Claude Lorraine (properly named CLAUDE GELLÉE), a celebrated landscape-painter, was a native of Lorraine, and born in 1600. According to Baldinucci, a relative who travelled as a lace-dealer took Claude when still a boy to Italy, but deserted him in Rome. However, he soon found employment in grinding colours, and doing other menial services for Agostino Tassi, a landscape-painter, from whom he gained some knowledge of art. He seems next to have studied under Godfrey Waals at Naples, and after some time spent in wandering through various portions of Europe, he finally settled at Rome in 1627. Here he made his way slowly with the public, and it was about ten years afterwards that he received a commission from Cardinal Bentivoglio, who introduced him to Pope Urban VIII., for whom he executed four landscapes, two of which, 'La Fête Villageoise' and 'Un Port de Mer au Soleil Couchant,' both dated 1629, are now in the Louvre. His position was

now assured, and his works were much sought after. During his later years he suffered from gout and other maladies, and died in November 1682.

Claude's landscapes, which number about four hundred, are found in the chief galleries of Italy, France, Spain, and Germany, and in particular England, which, according to Dr Waagen, contains fifty-four paintings by Claude. Four of his best works—the landscapes known as 'Morning,' 'Noon,' 'Evening,' and 'Twilight'—are in the imperial gallery at St Petersburg. The painting on which Claude himself set the highest value is the 'Villa Madama.' He kept it as a study, and refused to sell it, even when Pope Clement IX. offered for it as much gold coin as would cover the canvas. As Claude's paintings have always commanded very high prices, many copies and imitations have been imposed on buyers. This was the case even during the artist's lifetime; for he set high prices on his works. It has been stated that it was in order to stop the fraudulent trade carried on in his name that he collected the sketches of his pictures in six books titled *Libri Veritatis*, which are now in the library of the Duke of Devonshire; but these were probably executed simply to preserve a record of the works and of their destination. They were engraved in mezzotint by Earlom, and it was in rivalry with these prints that Turner executed his celebrated *Liber Studiorum*.

Claude was an earnest, indefatigable student of nature, of which, however, he possessed a far less close and scientific knowledge than is evinced by the works of many modern landscape-painters. He was restricted in his range of subjects and effects, and he had little sympathy with nature in her wilder and sterner moods. On the other hand, his composition, if rather formal, is always graceful and well considered; his colour is singularly mellow and harmonious; and as a sky-painter his work is full of delicacy and great tenderness of gradation and aerial quality. Claude produced about thirty etchings, the best of which are distinguished by great technical skill, refinement, and freedom. Hamerton has pronounced 'Le Bouvier' to be in many ways 'the finest landscape etching in the world.' His plates have been recently reproduced by Amand-Durand, and they are catalogued by Meunier in *Le Peintre-Graveur Français* of Robert-Dumesnil. His figures, in which he was sometimes aided by other painters, are in general such inferior accessories that he was wont to say he made no charge for them when he sold his pictures. See Ruskin's *Modern Painters*; Mrs Mark Pattison (Lady Dilke), *Claude Lorraine, sa Vie et ses Œuvres* (Paris, 1884); Dullea, *Claude le Lorrain* (Lond. 1887).

Claudianus, CLAUDIUS, the latest of the great Latin poets, a native of Alexandria, flourished in the end of the 4th and beginning of the 5th century. He wrote first in Greek, which appears to have been his native tongue, though he was originally of Roman extraction; but in Gibbon's words, he 'assumed in his mature age the familiar use and absolute command of the Latin language; soared above the heads of his feeble contemporaries, and placed himself, after an interval of three hundred years, among the poets of ancient Rome.' His poems brought him into such reputation that, at the request of the senate, the Emperors Arcadius and Honorius erected a statue in honour of him in the forum of Trajan. The productions of Claudianus that have come down to us consist of two epic poems, *Raptus Proserpinæ* and the fragmentary *Gigantomachia*; besides panegyrics on Honorius and Stilicho, *Eidyllia*, *Epigrammata*, and occasional poems. Claudianus displays a brilliant fancy, rich colouring, with variety and distinctness in his pictures; but he is

often deficient in taste and gracefulness. Editions of his works were published by Gessner (1759), Burmann (1760), and Jeep (Leip. 1876-79).

Claudius I., Roman emperor, whose full name was Tiberius Claudius Drusus Nero Germanicus, was the younger son of Drusus, brother of the Emperor Tiberius and Antonia, and was born at Lyons in Gaul, 10 B.C. He was naturally sickly and infirm, and his education was neglected, or left to be cared for by women and freedmen. His supposed imbecility saved him from the cruelty of Caligula; but Claudius, in his privacy, had made considerable progress in the study of history, and wrote in Latin and Greek several extensive works now lost. After the assassination of Caligula, he was found by the soldiers in a corner of the palace, where, in dread, he had concealed himself. The praetorians carried him forth, proclaimed him emperor, and compelled his recognition by the senate and many citizens who had hoped to restore the republic. By giving largess to the troops who had raised him to the throne, Claudius commenced the baneful practice which subjected Rome to a military despotism under the succeeding emperors. The first acts of his reign seemed to give promise of mild and just government, but in the year 42, when a conspiracy against his life was detected, his timidity led him to yield himself entirely to the guidance of his third and most infamous wife, Messalina, who, in concert with the freedmen Pallas and Narcissus, practised cruelties and extortions without restraint. The emperor meanwhile lived in retirement, partly occupied in his studies, and expended enormous sums in building, especially in the famous Claudian Aqueduct (*Aqua Claudia*). At the same time he ruled well though mildly, and carried out the enlightened policy of extending citizenship to the provincials. Abroad his arms were victorious. Mauritania was made a Roman province, the conquest of Britain was commenced, and the frontier provinces in the east were settled. At home the uxorious emperor continued to be governed by his wives. Tacitus tells us that the shameless Messalina, after abusing her blind and doting husband by a series of the vilest profligacies, went so far as to marry herself publicly to a young lover, on which the emperor, at last awakened to her wickedness and his own shame, put her to death. He next married his own niece, the equally vicious and more cruel Agrippina, who procured his death by poison (54 A.D.) in order to secure the succession of Nero, her own son by an earlier husband.

Claudius, Appius, a Roman decemvir (451 and 450 B.C.), who gained the high favour of his fellow-citizens by his ability and activity. In the latter year, however, he began to show his real aims towards absolute and illegal power. The growing indignation of the Roman populace reached a height on account of his grossly tyrannous action towards Virginia, daughter of a respected plebeian named Lucius Virginus, who was abroad with the army. The proud patrician gained possession of the person of the maiden by pretending that she was the born slave of one of his clients. Her lover Icilius summoned her father Virginus from the army, but another mock-trial again adjudged the girl to be the property of the decemvir's client. To save his daughter from dishonour, the unhappy father seized a knife and slew her. The popular indignation and the father's appeal to the army overthrew the decemviri, and the proud Appius was flung into prison, where he died by his own hand. The story is specially familiar to English readers from Macaulay's *Lays*. The Claudian *Gens* was one of the most numerous and important of the patrician tribes of Rome; and besides the sons

and grandsons of the decemvir, there were numerous persons of distinction who bore the name of Appius.

Claus, KARL, zoologist, born 2d January 1835, at Cassel, became professor successively at Würzburg (1860), Marburg, Göttingen, and Vienna (1873). His principal work is the *Grundzüge der Zoologie* (4th ed. 1878-82).

Claus, SANTA. See NICOLAS.

Clause. See DEED.

Clausel, BERTRAND, a French marshal, was born at Mirepoix, Ariège, 12th December 1772, and obtained distinction in the Italian and Austrian campaigns of Napoleon; but more especially as commander in Spain, after the battle of Salamanca in 1812. Condemned to death as a traitor on the return of the Bourbons, he was in 1820 permitted to return from America to France; commanded the army and was governor in Algeria in 1830; and was made governor-general of Algeria in 1835. He returned to France in 1836, voted with the opposition in the Chamber, and died 21st April 1842. See ALGERIA.

Clausewitz, KARL VON, a very distinguished Prussian general, whose writings prepared the way for a complete revolution in the theory of war, was born 1st June 1780 at Burg. He served with distinction in several campaigns in the Prussian and in the Russian service, in 1815 became chief of a Prussian army corps, and was ultimately director of the army school, and inspector of artillery. He died of cholera at Breslau, 16th November 1831. Of his works the best known are his great book on war, *Vom Krieg* (3 vols. 4th ed. 1880), and his life of Scharnhorst. See his Life by Schwartz (Berlin, 1877).

Clausius, RUDOLF, a great German physicist, born 2d January 1822 at Köslin in Pomerania. He studied at Berlin, and afterwards lectured on natural philosophy as *privat-docent* at Berlin, and as professor at the Zürich Polytechnic School. In 1869 he was appointed to the chair of Natural Philosophy at Bonn, and here he died, August 24, 1888. He was elected a foreign member of the Royal Society in 1868, and in 1879 was given its highest honour, the Copley Medal. His scientific labours cover parts of the field of optics and of electricity, but his especial work was his contribution to the science of thermo-dynamics, the honour of establishing which on a scientific basis he divides with Rankine and Thomson. His mathematical methods he also applied to the theory of the steam-engine, the dynamical or kinetic theory of gases, and to electricity and electro-dynamics. His great work is his *Abhandlungen über die mechanische Wärmetheorie* (1864, and 1867), which in its second edition took a more systematic form as vol. i., *Die mechanische Wärmetheorie* (1876), and vol. ii., *Die mechanische Behandlung der Electricität* (1879). Other books are *Ueber das Wesen der Wärme* (1857), and *Die Potentialfunction und das Potential* (3d ed. 1877).

Clavagella. See KLAUSTHAL.

Clavagella, or CLUB-SHELL, a genus of marine Lamellibranchiate Molluscs of the same family with *Aspergillum* (q.v.). They mostly live in excavated holes in rocks or in masses of coral. The ordinary form of the bivalve shell is curiously modified. One valve (the right) is fixed to the inner surface of the chamber in which the animal lives, and is continued without interruption into a secondary shell-tube, which extends from the chamber outwards, and varies considerably in length in different species. The left valve is free and movable on the right. The mode of excavation is not known. Six living species of wide

distribution are known. The fossil forms, which

Clavagella lata, showing the cavity and fixed valve:
a, the fixed valve; b, the calcareous tube.

are more numerous, were first discovered. They do not occur below the Upper Chalk.

Clavaria, a genus of Fungi, of the order Hymenomycetes, family Clavariaceae, in which the spore-bearing tissue is produced over all parts of the surface. The species are numerous, some of them simple and club-shaped, some branched. *C. botrytis*, a species common in oak and beech woods, especially in Germany, growing on the ground, among moss, grass, heath, &c., is gathered when young and used as food, having a very agreeable sweetish taste. Other species, notably *C. flava*, *coralloides*, *aurea*, and *formosa*, are used in the same way.

Claverhouse. See GRAHAM OF CLAVERHOUSE.

Clavichord, an obsolete instrument of the same type as the Harpsichord (q.v.) and Spinnet (q.v.). A *Clavicharp* is a harp struck with keys like a piano.

Clavicle, an important part of the pectoral girdle of Vertebrates, perhaps most familiarly known in the collar-bone of man and in the merry-thought of birds. It is well developed in those mammals in which the fore-leg or arm is used very strongly and freely, but is poorly developed or absent in many cases, as in Carnivores and Ungulates. In most flying birds it is strong, and often fused to the breast-bone; in the ostrich tribe it is rudimentary or absent. It is not a prominent bone in reptiles, being absent in snakes and crocodiles, apparently continuous with the scapula in tortoises, and in fact only well seen in the majority of lizards. A 'clavicle' is also to be seen in most Amphibia, though its exact relations are much disputed. A prominent part in the girdle of ordinary bony fishes is also called the 'clavicle,' but it is not certain that it corresponds to that of higher vertebrates. Of the clavicle generally it may be said that it is a paired bone superadded from the skin as an auxiliary to scapula and coracoid, that its position is ventral and anterior to the coracoid, and that it is often associated with an interclavicle. See BIRD, BONE, SKELETON; also Huxley's *Anatomy of the Vertebrate Animals*, and other works on Comparative Anatomy, such as those of Gegenbaur and Wiedersheim (translated by Professors Bell and Parker). There is a separate article on the human COLLAR-BONE (q.v.).

Clavicornia, a name sometimes applied to several tribes of beetles with club-shaped (clavate) antennae. They are included within the great Pentamerous section of Coleoptera. Burying beetles illustrate the type.

Clavijero, FRANCISCO XAVIER, Mexican historian, born at Vera Cruz in 1721, entered the order of the Jesuits in 1748, and became a teacher of rhetoric and philosophy. On the suppression of the Jesuits in Spanish America in 1767, Clavijero retired to Italy, where he died at Bologna in 1787. He wrote in Italian a *History of Mexico*, an impartial and valuable work, of which an English translation by C. Cullen was published in 1787.

Claws, sharp hardenings of the skin at the end of appendages. The term is often applied to the chela and similar structures at the end of Arthropod limbs, but is best restricted to the epidermic tips found at the ends of the digits in most reptiles, on the toes, and often on the thumb and first finger of birds, but seen in perfection in many mammals—e.g. Carnivores, Insectivores, Edentates. It is obviously impossible to draw any sharp line between claws and Nails (q.v.).

Clay (A.S. *clæg*; of the same root as 'clag,' 'claggy'), a term applied, in a vague way, to those kinds of earth or soil which, when moist, have a notable degree of tenacity and plasticity. The clays are not easily distinguished as rock species, but they all appear to owe their origin to the decomposition of various rocks, and to consist chiefly of aluminic silicate, along with other ingredients, which vary in character with the nature of the parent rock from the degradation of which they are derived. Thus common clay is a mixture of kaolin or China clay (which is a hydrated clay), and the fine powder of some felspathic mineral, which is anhydrous and not decomposed. Clays vary much in plasticity—all being more or less plastic when moistened with water, and capable of being moulded into any form. But while many retain their shape when dried by heat, others, which in the damp state would ordinarily be called clays, tend to fall to powder when all the water is driven off. Clay is eaten by the Botocudos and other savage tribes, as also in Georgia and the Carolinas by negroes and 'poor whites.' The plastic clays are used for many purposes, as for making pottery of all kinds, bricks and tiles, tobacco-pipes, firebricks, &c. The following are the commoner varieties of clay and clay-rocks: *China clay* or *Kaolin* (q.v.); *Pipeclay* (q.v.), very like kaolin, but containing a larger percentage of silica; *potter's clay*, not so pure as the preceding; *sculptor's clay* or *modelling clay*, a fine potter's clay, sometimes mixed with fine sand; *plastilina*, a potter's clay from Italy, supposed to be composed of oil, glycerine, rosin, and powdered clay, which, as it does not shrink, need not be kept wet; *brick-clay* (see BRICKS), an admixture of clay and sand with some ferruginous matter; *Fireclay* (q.v.), containing little or no lime, alkaline earth, or iron (which act as fluxes), and hence infusible or highly refractory; *Shale* (q.v.), a laminated clay-rock; *clay-slate*, an indurated cleaved clay-rock; *Loam* (q.v.), a non-plastic mixture of clay and sand; *Marl* (q.v.), a clay containing much calcareous matter. Clay at the deepest sea-bottom is largely of animal origin. See ARGILLACEOUS ROCKS.

CLAY SOILS derive their character from the aluminic silicate which they contain in a state of mixture, as well as in chemical combination with other substances. Some soils contain so large a proportion of alumina as 35 per cent., but generally the proportion is much smaller. The felspars which chiefly yield the alumina of clay soils contain also soda, potash, and lime, substances which

tend to render clays fertile when under cultivation. The physical characters, however, of the different varieties of clay soils arising from the varying proportions of silica, and other substances mixed with the alumina, are chiefly concerned in their relative fertility. Calcareous matter exercises a considerable influence on their powers of producing crops. For an account of the distribution of soils in this country, see Johnston's and Cameron's *Elements of Agricultural Chemistry and Geology*.

Clay, CASSIUS MARCELLUS, a zealous abolitionist, born in Kentucky in 1810, graduated at Yale in 1832, and three years after was elected to the legislature of his native state. He opposed the annexation of Texas (1844); started at Lexington *The True American*, a vigorous anti-slavery paper, the following year; volunteered in the Mexican war (1846); supported Mr Lincoln in 1860; and from 1861 till 1869 was U.S. Minister to Russia. A true son of Kentucky, Clay delivered his political addresses armed to the teeth, was involved in a number of serious quarrels, and in 1877 was tried but acquitted on a charge of killing a discharged negro servant who had threatened his life. See his *Life, Writings, and Speeches* (2 vols. 1886).

Clay, HENRY, statesman, one of the 'great triumvirate' of American orators, was born in 'the Slashes,' a district of Hanover county, Virginia, April 12, 1777. He was the son of a Baptist preacher who died in 1781, and from the employment of some part of his early youth in connection with a grist-mill, he earned the cognomen of 'the mill-boy of the Slashes.' His early schooling was but scanty. When fifteen years old he became an assistant-clerk in the chancery court of his native state, and for four years was amanuensis to that excellent lawyer and true patriot, George Wythe, then chancellor. He also studied law for one year with Robert Brooke, attorney-general of Virginia. In 1797 he was licensed to practise law, and in the same year went to Lexington, Kentucky, where he soon acquired a high reputation as an orator and as a jury lawyer. He was sent in 1806, and again in 1809, to the United States senate for short terms. He first entered the lower house of congress in 1811, and was chosen its Speaker. This position he filled for many years with great ability. He was active in bringing on the war of 1812-15 with Great Britain, and was one of the commissioners who arranged the treaty of Ghent which ended the war. By his course in regard to the 'Missouri Compromise' of 1821, he won the title of 'the great pacificator.' In 1824 he was one of the strongest advocates of a high protective tariff, and in the same year was one of the four candidates for the presidency. No choice having been made by the electoral college, Mr J. Q. Adams was elected president by the House of Representatives; and Clay's acceptance of the position of secretary of state under Adams was by many held to constitute a proof of a corrupt bargain between two statesmen, neither of whom, in truth, would have been guilty of countenancing such a bargain. Clay re-entered the senate in 1831, and in the same year was renominated for the presidency; but in the following year General Jackson was re-elected to that office. His candidature for the office of president in 1844 was in like manner unsuccessful. The compromise of 1850 between the opposing free-soil and pro-slavery interests was largely Clay's work. He died July 29, 1852. Although he was the most attractive public speaker in his country during what is justly regarded as 'the golden age of American oratory,' his ability as a reasoner was excelled by that of Webster; while his other principal

rival, Calhoun, surpassed him in intensity and fiery earnestness. No man had a larger following of devoted personal friends than Clay, and for more than forty years he had a very conspicuous share in shaping the legislation of the republic. As a public man his career was without a blemish. Of the rather numerous biographies of Clay the best is that by Carl Schurz (Boston, 1887).

Clay Cross, a town in Derbyshire, 4½ miles S. of Chesterfield, the centre of a coal and iron district. The collieries here were begun by George Stephenson in 1838. Pop. (1881) 6879.

Clay Ironstone, a granular or compact admixture of the mineral *siderite* (ferrous carbonate) and clay. It occurs as nodules or in thin beds in various geological systems, but especially in the carboniferous strata. It frequently contains organic matter. When very highly carbonaceous, it passes into the variety called blackband ironstone. See IRON ORES.

Claymore (a Gaelic term meaning 'the great sword') is properly used of the old Celtic one-handed, two-edged longsword, often engraved on ancient tombstones, with the guards pointing downwards. The name is now commonly given, inaccurately, to the basket-hilted sword of the officers of Highland regiments.

Clayton, JOHN MIDDLETON, statesman, was born in Sussex county, Delaware, 24th July 1796, studied at Yale, and practised as a lawyer. In 1829 he became a United States senator, and while secretary of state in 1849-50, he negotiated the Clayton-Bulwer Treaty with Britain, guaranteeing the neutrality of lines of interoceanic communication across Nicaragua or elsewhere. He died 9th November 1856. See BULWER.

Clazom'ene, one of the twelve cities of Ionia which stood on the gulf of Smyrna, westward from Smyrna. Under the Romans it was a free city, and had an extensive commerce. It was the birthplace of Anaxagoras. It is now called Vurla.

Cleanthes, a Stoic philosopher, born at Assos, in Troas, about 300 B.C. His poverty was such that he had to work all night at drawing water in order to obtain money for his support and to pay his class-fee while attending the lectures of Zeno—a fact discovered only when the Areopagus called upon the ardent young student to show how he obtained his living. For nineteen years he listened patiently to the great Stoic, and, on his death, succeeded him in his school. He died of voluntary starvation when about eighty years old. Cleanthes differed from the other Stoics in regarding the sun as the governing principle of the world; but none of his writings are extant except a *Hymn to Zeus*, one of the purest and noblest pieces of poetry in the Greek language, showing an admirable union of religious feeling and philosophic thought.

Clear, CAPE, a headland of Clear Island, the most southerly point of Ireland, with a lighthouse and telegraph station. Clear Island, 66 miles SW. of Cork, is 1504 acres in area. Pop. 594.

Clearing-house. The business facilities afforded by bankers to their customers in collecting their bills, cheques on other firms, and similar obligations, early necessitated an organised system of interchanging such documents, whereby labour might be saved, and the cash-balances required in settlements reduced. It is claimed by a French writer that the *Chambre de Compensation de Lyon*, as reorganised in 1667, was practically similar to the modern clearing-house; and the Scottish bank-note exchanges (a species of clearing) were established as far back as 1752. The present system, however, originated in London at an unknown date. It is said that the clerks, when collecting

from the various banking-houses, began to interchange the documents of mutual indebtedness in the street, and subsequently at taverns or any banking-office where they were tolerated. Some time previous to 1778 a special apartment was devoted by the bankers to the purpose; and in 1810 the building in Lombard Street, since known as the 'Clearing-house,' was set apart for the clearing, under the direction of a committee of bankers, and the immediate management of two inspectors. The joint-stock banks were not admitted to the clearing-house until 1854. Four years later the country-cheque clearing was established as a department of the clearing-house. In 1864 the Bank of England entered, but it clears only *against* the other banks. Only twenty-seven banks, including the Southwark branch of the London and Westminster Bank, are members. Other London bankers arrange with clearing banks to represent them.

The system pursued is as follows: From time to time during the day, each firm transmits to the clearing-house cheques and bills payable by other bankers, classified according to the banks retiring them, account being also taken of obligations coming against their firm. At a certain hour the doors are closed, and the balances struck. Time is allowed for each bank to decide as to honouring the drafts upon it, after which the final adjustment of balances takes place. Subjoined is an actual balance sheet as at the close of a day's clearing.

252,355	3	11	Balance				
651,824	19	5					

The figures in either column are the sums due to or by Glyn & Co. in account with each of the other members of the clearing-house, after allowing for their mutual indebtedness; the differences as they occurred that day being also shown interlined; as well as the total amount of vouchers returned unpaid. The result was that after placing all their claims on the other banks against the claims of the latter on them, there remained a sum of £252,355, 3s. 11d. due by Glyn & Co. on the general balance. This was more than accounted for by the claims of the Bank of England, who only clear on one side. Each bank makes up a similar form. The inspectors having satisfied themselves that the general balance is correct (all the members having agreed

between themselves, and the total *debtor* balances equalling the *creditor*), warrants for settling the balances by transfer at the Bank of England, certified by the inspectors, are passed between the members. Formerly these balances were settled in cash. Thus, transactions to the amount of several millions daily are settled without the use of a bank-note or coin. The importance of the system is illustrated by the fact, stated in evidence before the House of Commons, that the London and Westminster Bank, by getting admission to the clearing-house, were enabled to reduce their cash-balance by £150,000.

The record of the total amount of bills, cheques, and drafts passing through the clearing-house is regarded as an index of the state of trade; and as London is the chief centre of trade for the world, this record has a world-wide range. The sums passed through the clearing-house are greatest on certain 'special days.' These are (1) the 4th of the month, trade bills being mostly dated on the first of the month, and, with three days' grace, falling due on the 4th of some succeeding month; (2) consols settling days, once a month; (3) Stock Exchange settling days, twice a month. The following figures, commencing with the earliest record, show the magnitude and growth of the clearing-house work: (1839) £954,401,600; (1868) £3,425,185,000; (1873) £6,070,948,000; (1878) £4,992,398,000; (1883) £5,929,404,000; (1887) £6,077,097,000. The highest record was in 1881, £6,357,059,000. In most of the large towns in England there is now a clearing-house, and in Scotland the system, including the separately conducted note-exchanges, has been thoroughly organised, so that clearings take place all over the country, balances being settled in Edinburgh.

The first clearing-house in America was started in New York on 11th October 1853, and the system has since assumed enormous proportions throughout the United States; in 1888 there were upwards of 30 clearing-houses. The progress of the New York clearing-house will be seen from the following figures for the years ending 30th September (1854) £1,150,091,197; (1868) £5,696,857,727; (1873) £7,092,210,565; (1878) £4,501,687,688; (1883) £8,058,633,051; (1887) £6,974,569,757.

The system has more recently spread to the continent of Europe. *La Chambre de Compensation des Banquiers de Paris* was formed March 1872, the clearing-house of Berlin in 1883, and that of Vienna in 1864; but their transactions are greatly less than those of London and New York. While it was in connection with banking that the clearing-house system originated, the principle (in modified forms) has been adopted by other departments of business. The London Railway Clearing-house was founded in 1842, the Stock Exchange Clearing-house in 1874, and others more recently. See Howarth, *Our Clearing System* (1886); François, *Clearing House et Chambres de Compensation* (Lille, 1887); *The New York Clearing House, its Methods and Systems* (New York, 1888).

THE RAILWAY CLEARING-HOUSE is an association instituted to enable railway companies in Great Britain to carry on, without interruption, the through traffic in passengers, animals, minerals, and goods passing over different companies' lines of railways, and to afford to the traffic the same facilities as if the different lines had belonged to one company. The arrangements are conducted in London by a committee, the members of which are appointed by the directors of the companies who are parties to it; and the association is regulated by the Railway Clearing Act, 1850. The companies are each represented on the committee by a delegate. The committee holds stated meetings four times a year, and oftener if necessary.

Subordinate committees of railway officers also meet from time to time. The accounts of the clearing system, and the balances due to and from the several companies, are settled and adjusted by the secretary of the committee, with appeal to the committee, whose decision is final. The clerks at stations of the various companies send abstracts of all traffic monthly. The collected passenger-tickets are also sent monthly. Number-men are employed by the clearing-house at junctions where the lines of different companies meet, who note the number of every carriage, horse-box, wagon, van, and sheet or wagon-cover on the train going beyond the parent line, and make weekly returns. The returns from the companies' stations, together with those of the number-men, enable the accounts of mileage and demurrage incurred to be made up by the clearing-house, by whom the companies are debited and credited, as the case may be. A debtor and creditor account is sent from the clearing-house monthly to each company, showing on the one side in one sum what the company has to receive from all other companies as their proportion of through passenger fares, through goods and parcels rates, and mileage and demurrage of carriages, wagons, and sheets; and on the other side, also in one sum, what the company has to pay to others out of moneys drawn by them. The balance is struck as against, or in favour of, the clearing-house (as a common debtor or creditor). In addition to declaring the balances, the clearing-house supplies to each company monthly statements of the details of the traffic of each station.

The number of companies parties to the clearing system was recently between sixty and seventy, including practically all the working railway companies of Great Britain; and the amount of business of an intricate kind which was involved may be judged of from the foregoing particulars, and from the number of separate settlements, which amount to eleven and a half millions per annum, representing seventeen millions of money. The staff now numbers nearly two thousand. Regulations are published annually by the clearing-house for the guidance of the different companies in connection with the system.

The clearing-house system is made available also for the recovery of lost articles of luggage. Reports giving the description of each lost article are sent from all stations daily to the clearing-house, and by this means almost all lost luggage is restored to the owners. The reports number nearly half a million per annum. The government scheme of the parcel post involves a quarterly payment by the Post-office to the whole of the railway companies of Great Britain and Ireland, and the apportionment as between the companies is effected through the machinery of the clearing-house. There is a similar railway clearing system in Ireland, with its headquarters in Dublin.

The general railway clearing-house has never been established in the United States, but there are several of limited extent, each embracing such lines as belong to an individual system. Thus, one at Philadelphia is a common centre for an association of lines, with about forty members. Others are at Atlanta (Ga.), Louisville (Ky.), Boston (Mass.). There are besides various railway commissions, pools, and associations partaking of the nature of a limited clearing system.

Clearing-nut (*Strychnos potatorum*), a small tree of the same genus with the Nux Vomica (q.v.), abundant in the forests of India, and of which the seeds are much used for clearing water. They are sold for this use in the bazaars, and travellers commonly carry some with them. These seeds being rubbed on the inside of a vessel, muddy water put

into it quickly becomes clear, all impurities settling to the bottom.

Clear-story. See CLERESTORY.

Cleator Moor, a town of Cumberland, 4 miles SE. of Whitehaven, with coal-mines and iron-furnaces. Pop. of parish (1861) 3995; (1881) 10,420.

Cleats, in Shipbuilding, are pieces of wood or iron fastened to various parts of the vessel, and having holes or recesses for fastening ropes. There are several kinds, applied to various purposes.

Cleavage, or SLATY CLEAVAGE, is a condition of rocks in which they split easily into thin plates. In true bedding the layers of rock correspond to planes of deposition or accretion, but in slaty cleavage the planes along which the rock splits may or may not coincide with bedding-planes. In point of fact they rarely do, but intersect the bedding-planes at all angles. Slaty cleavage is a superinduced structure—the result of the extreme compression which the rocks have undergone while they were being squeezed into anticlinal and synclinal folds (see ANTICLINE). When thin

Section exhibiting Lines of Cleavage.

sections of clay-slate are examined microscopically, the grains of which the rock is composed are found to be flattened or compressed, and drawn out in the direction of the cleavage planes. Although slaty cleavage is best developed in homogeneous fine-grained clay-rocks, it yet occurs in many coarse-grained rocks as well, but in these the cleavage is never so perfect as in the finer-grained clay-rocks. As induration necessarily accompanies cleavage, the cleaved clay-rocks become of great economic importance, and are familiar to every one in the common blue and purple roofing-slates.

Cleavers, or GOOSE-GRASS (*Galium Aparine*), a species of Bedstraw (q.v.), a coarse Rubiaceous annual, with whorls of six to eight leaves, both stem and leaves rough with reflexed bristles, the fruit also hispid, and when ripe distributed by adhering like a bur to any animal which may brush against it. A very common weed in hedges and bushy places in Britain and most parts of Europe and North America, it was formerly of repute in domestic medicine as a diuretic. From the time of Dioscorides, and it is said still in Sweden, its prickly stems have been used as a strainer for milk.

Clef, a musical character placed on the staff, by which the absolute pitch of the notes is fixed. There are three clefs—viz. the G, the C, and the F clef. The G clef is placed on the second line, and the stave with this clef is known as the treble stave; the C clef on the third line as the alto stave; and the F clef on the fourth line as the bass stave. The C clef is a fifth below the G clef, and a fifth above the F clef, thus:

The C clef is also placed on the fourth line for some instruments, and for the tenor part in vocal music,

thus: ; and in old vocal music, and also in full scores, the C clef placed on the first line is used for the soprano.

Cleg, a name given to some insects of the dipterous family Tabanidae, the females of which are in summer extremely troublesome to horses, cattle, and human beings.

Cleg (*Chrysops cecutiens*).

Some of them are well known as 'breeze-flies.' The females pierce the skin of their victims by means of formidable lancet-like mouth organs, and greedily suck the blood from the wounds. The name cleg is sometimes given in England to *Chrysops cecutiens*, a fly frequent in most parts of Europe, but rare in Scotland. It often attacks man, and not unfrequently inserts its proboscis through the sleeve, or some other part of the dress. It is about one-third of an inch in length, mostly black, with yellow markings on the abdomen, and very large eyes of the most beautiful green and golden colours. The insect always called cleg in Scotland is *Hematopota pluvialis*—a rather smaller but equally troublesome fly, mostly of a gray colour, but also remarkable for its very large and beautiful eyes, which are greenish, with waved purplish-brown bands. In England it is sometimes called the *Stout*. It is particularly common in low damp places.

Cleland, WILLIAM (1861-89), Covenanting poet. See CAMERONIAN REGIMENT.

Clem'atis (Gr. *clēma*, 'the shoot of a vine'), a genus of plants of the natural order Ranunculaceae, having four coloured sepals, no corolla, and for fruit numerous one-seeded achenia with long—generally feathery—awns. The species are pretty numerous, herbs or shrubs, generally with climbing stems, natives of very different climates, and much scattered over the world. They possess more or less active caustic properties. The long awns give the plants a beautiful appearance even in winter. The flowers of many species are also beautiful. *C. vitalba*, the common Traveller's Joy (fancifully so named because of its ornamental appearance by the wayside), is the only native of Britain.

Clematis montana.

It is common in the south, but becomes rarer towards the north, and is scarcely found in Scotland. The twigs are capable of being made into baskets. It rapidly covers walls or unsightly objects. The fruit and leaves are acrid and vesicant, the leaves are used as a rubefacient in rheumatism; and those of other species are also employed in the same way. In ornamental gardening the genus is a most important one. A number of species and many garden varieties are of the

greatest beauty, and most profuse in flowering. The flowers of some in different varieties attain the diameter of from 4 to 8 inches, and range in colour from pure white to pale azure, deep purple, and claret or ruby. In the United States there are many native species. A beautiful evergreen species from New Zealand, *C. indivisa*, with pure white flowers, is one of the handsomest of greenhouse climbers; and *C. flammula*, a native of southern Europe and northern Africa, with white flowers, which have a very strong honey-like smell, is the species known as Sweet Virgin's Bower. The garden varieties are propagated by grafting the young shoots in spring on the roots of such common species as *C. vitalba* and *C. flammula*. Many are propagated by cuttings, and all may be increased by seeds, but the garden varieties cannot be depended upon to come true by that means.

Clemens, SAMUEL LANGHORNE ('Mark Twain'), an American humorist, was born at Florida, Missouri, November 30, Copyright 1899 in U.S. 1835. He learned the trade of a printer, and afterwards acted as a pilot on the Mississippi River. From a well-known call of the man sounding the river in shallow places ('Mark twain,' meaning 'by the mark two fathoms') his pseudonym as a writer was subsequently taken. After the outbreak of the war of 1861-65, he went to Nevada, where he tried silver-mining; next he edited for two years the Virginia City *Enterprise*, to which he had previously contributed as 'Mark Twain'; and in 1864 moving to San Francisco, became a journalist, and lectured with success there and in New York. In 1867 he joined a pleasure party going abroad, and visited France, Italy, and Palestine, gathering material for his *Innocents Abroad* (1869), which established his reputation as a humorist, 125,000 copies selling within three years. He was afterwards an editor at Buffalo, New York, with an interest in the *Express*, where he married Miss Langdon, a lady of wealth. He, later, removed to Hartford, Connecticut. His books have been mostly sold by subscription, and have yielded him a large income. He is a member of the publishing firm of Charles L. Webster & Co. He was made M.A. of Yale in 1888. His humour, however grotesque, is never laboured, never mean or ungenerous; it is singularly direct and simple in form, and has appealed as successfully to British as to American readers. 'If the prevailing spirit of Mark Twain's humour,' writes Mr Howells, 'is not a sort of good-natured self-satire, in which the reader may see his own absurdities reflected, I scarcely should be able to determine it.' Mr Clemens has varied much of his work by excellent character-sketches and graphic descriptions. Among his books are *The Innocents Abroad* (1869); *Loughing It* (1872); *The Gilded Age* (1873), the last written with the co-operation of Mr Charles Dudley Warner, and published both as a story and as a comedy, in which shape it had great success; *Tom Sawyer* (1876); *A Tramp Abroad* (1880); *The Prince and the Pauper* (1882); *Life on the Mississippi* (1874, re-issued 1883); *The Adventures of Huckleberry Finn* (1885); and a compilation, *Library of Humour* (1888). All these have been republished in England, and translations of his principal works have appeared in Germany.

Clement. CLEMENS, or CLEMENT, is the name of seventeen popes, few of whom require any special notice (see POPES). The first of the series, CLEMENS ROMANUS (so distinguished from Clement of Alexandria), is accounted one of the Apostolic Fathers (q.v.), and is reckoned variously as the second or third successor of St Peter in the see of Rome. A 9th-century legend makes him martyred in the Crimea in the year 102. His day

is November 23. Origen (185-254) was the first to distinctly identify Clement with St Paul's 'fellow-labourer' (Phil. iv. 3); but this assumption has nothing to support it, while the ancient tradition makes Clement the disciple of St Peter. Moreover, on a name so common endless theories may be built. Distinguished German scholars, such as Hilgenfeld, and Harnack (doubtfully), have identified the bishop with Flavius Clemens, cousin of the Emperor Domitian, whose sons had been named successors to the empire, and who was consul in 95 A.D., and in the same year put to death on a charge of 'atheism' and 'Jewish manners.' The most probable view is that advanced by Lightfoot—that Clement was a freedman of Jewish parentage belonging to 'Caesar's household'—strong arguments in support of which are set forth in his edition of the two *Epistles*. Of these, the so-called second epistle is really a homily, and is certainly not Clement's; but the first, although its genuineness has been earnestly disputed by the author of *Peregrinus Proteus* (Lond. 1879), is generally accepted. Chiefly hortatory and didactic, it is addressed to the Corinthian Church, in which serious feuds had arisen, and taints of social dissensions and of the resurrection, which is illustrated by a curiously circumstantial account of the phoenix. It was probably written about 95 A.D., and it was widely known and highly esteemed at an early date. Clement would appear to have had some reputation among his contemporaries as a letter-writer; Hermas (q.v.) represents himself as directed by the angel to deliver a copy of his *Shepherd* to him, that he may transmit it to the cities abroad, 'for this function belongs to him.' To-day the epistle is chiefly of interest as the first though innocent step towards papal aggression, and for what Lightfoot calls its *liturgical* position. There is no respectable evidence that it was ever placed in the same catalogue with the canonical books, but in the church at Corinth it was publicly read from time to time, and by the 4th century this use had extended to other churches. For convenience of reading it would be attached to MSS. of the New Testament, as is the case in the famous Alexandrian MS. of the 5th century; but neither on this fact nor on its insertion in the forged Apostolic Canons can any argument be based; and it is only in the late Syriac MS. that it actually appears with the catholic epistles. The first edition was edited by Patrick Young in 1833, from the mutilated and incomplete Alexandrian MS., then in the king's library. This was the only copy known to the world until in 1875 Bryennios (q.v.) published a complete MS. (dated 1056) found at Constantinople, and in 1876 a complete Syriac MS. (1170) came into the possession of Cambridge University. See Lightfoot's scholarly and exhaustive edition (1869; appendix, 1877), where the second epistle will also be found. Quite a mass of literature has sprung up around the name of Clement, but the other works attributed to him—the Apostolic Constitutions and Canons (q.v.), two Syriac epistles on Virginité (MS. dated 1470; published 1752), the *Clementine* (the *Recognitions* and *Homilies*), and two epistles to James, which, with three forged Clementine letters, were in the 9th century incorporated in the notorious Isidorian Decretals—are all undoubtedly spurious. The *Clementine* is a fiction of which St Peter is the hero; it was regarded by Baur and the Tübingen school as the most notable outcome of the Ebionite party in the early Christian church, and on it much of their theory is based; the *Recognitions* (the Latin form, preserved by Rufinus) have been edited by Gersdorf (1838), the *Homilies* (the Greek form) by Schwegler (1847), Dressel (1853), and De Lagarde (1865).

For the *Epistles to Virgins*, see Beelen's edition (Louvain, 1856), and Funk (Tüb. 1881); for their source, see Cotterill's elaborate and convincing *Modern Criticism* (Edin. 1884).

CLEMENS, TITUS FLAVIUS, a celebrated father of the Christian church, was born probably at Athens, of heathen parents, about the middle of the 2d century, and resided during great part of his life in Alexandria, whence the epithet *Alexandrinus*. In his earlier years he devoted himself with great zeal to the study of philosophy, and wandered far and wide in quest of truth. The date of his conversion is unknown, but it is certain that after coming to Egypt, and listening to the prelections of Pantænus, he joined the Alexandrine Church, and was made a presbyter. Afterwards he became assistant to his master, whom he succeeded, about 190 A.D., as head of the celebrated Catechetical school. In 203 the persecution of the Christians under Severus compelled him to flee to Palestine. The only later notice we have of him is as the bearer of a letter from his pupil Alexander, afterwards Bishop of Jerusalem, to Antioch; and the date and place of his death are matters of pure conjecture, some writers putting it in 213, others as late as 220. His most distinguished pupil was Origen. Clement held a place in the Western martyrologies until the 17th century, when his name was omitted by Clement VIII. from the revised Roman martyrology; but in France, at least, he has never lost his title, his festival is still celebrated on the 4th December, and his name appears in the popular list of saints whose names may be given to children at baptism.

The chief writings of Clement that have survived, besides a practical treatise, *Who is the Rich Man that is Saved*, are the *Missionary*, the *Tutor*, and the *Miscellanies*, which form a connected series, probably continued in his lost *Outlines*, which was an investigation of the canonical writings. The first is an exhortation to the Greeks to abandon idolatry; the second, an exposition of Christian ethics; and the third, a collection of treatises and brief observations on Greek and Christian literature, designed as an introduction to Christian philosophy. They show that Clement, when he became a Christian, did not cease to be a philosopher. His liberal mind saw in science not a gift of devils, but of God through the Logos; Greek philosophy was part of the divine education of man, and his teaching is the result of the lofty purity of character that led him to seek the truth alike from heathen writers and from Christian heretics, believing that all that comes from God is good. The period in which he lived must also be taken into account: in his day all believers were regarded as in process of salvation; the distinction between the visible and invisible church had not yet been suggested, while Gnosticism offered to many minds an attractive solution of some obvious difficulties. Clement therefore distinguished between the ordinary believer and the Christian gnostic; above faith he placed knowledge, above salvation the more august glory and full spiritual life of the 'perfect man.' Faith implies knowledge, but imperfect knowledge; many things must be accepted in simple trust, until by contemplation and the practice of what is right the believer shakes himself free from the power of evil, and rises to intelligent sympathy with the divine will. And this system of spiritual evolution Clement extends to the future life, where the process of development is continued before the gnostic becomes as far as possible like God. Here are easily visible the germs of the later mysticism, just as his view of the Father as a pure Monad, undemonstrable, who can only be manifested through the Son, marks an important step in the progress of Neoplatonism. God and the cause of

all things he sought to discover in the simplest thing conceivable; and he went equally astray in making Christianity only a philosophy, and, as a means to a perfect life, the fullness of what had been partial in the Greek systems. Yet two truths he nobly taught—the present recovery of the divine likeness, and that formulated doctrine is not an end but a means to final knowledge. Clement's extant works exhibit a man of pure and gentle spirit, of sincere piety, of wide reading and of wider sympathies, and with a noble conception of the purposes of God's providence; but his learning is undigested, his quotations are often careless, and his turgid, verbose style and desultory method appear to have repelled most scholars. The best edition of his works is still that of Bishop Potter (1715), and others based on it; there is a translation in Clark's *Ante-Nicene Library* (1877-79), and a bibliography at the end of Dr Westcott's article in the *Dictionary of Christian Biography* (1877). Reference should also be made to Merk, *Clemens von Alexandria in seiner Abhängigkeit von der griechischen Philosophie* (Leip. 1879), and especially to Dr Bigg's able *Christian Platonists of Alexandria* (Bampton Lectures, 1886).

Clement XIV., GIOVANNI VINCENZO ANTONIO GANGANELLI, born in 1705 at Sant' Arcangelo, near Rimini, at the age of eighteen entered the order of Minorites, and studied philosophy and theology, which he afterwards successfully taught at Ascoli, Bologna, and Milan. He was the friend and confidant of Benedict XIV., who appointed him to the important post of counsellor to the Inquisition, and under Clement XIII. he was made a cardinal. He succeeded to the papal chair, May 19, 1769, after a conclave agitated by the intrigues of the Catholic sovereigns, who united in opposing every candidate favourable to the Jesuits. The new pope first set about reconciling these monarchs; he suspended the bull *In Cena Domini*, and entered into negotiations with Spain and France. After four years of deliberation, he issued in 1773 the famous brief *Dominus ac Redemptor noster*, suppressing 'for ever' the society of the Jesuits. The motive assigned in the brief is, 'regard to the peace of the church.' From this time his strength gradually gave way, and he died September 22, 1774, of poison, it was said, although no evidence has been produced to verify this suspicion. Clement was remarkable for liberality of mind, address as a statesman, sound learning, and integrity of character. He cherished the arts and sciences, and was the founder of the Clementine Museum, which, by the additions of Pius VI. and Pius VII., became the chief ornament of the Vatican. See Theiner, *Geschichte des Pontifikats Clements XIV.* (Paris, 1853; also in French).

Clement, JACQUES, the assassin (1589) of Henry III. (q.v.) of France.

Clementi, MUZIO, one of the best of pianists and composers for the pianoforte, was born in 1752 at Rome, where he competed successfully for a post as organist at the age of nine. Before he was fourteen, he had composed several contrapuntal works of considerable size, one of which, a mass, had produced some sensation in Rome; he then attracted the notice of an Englishman, Peter Beckford, M.P., who brought him to England, and at whose house in Dorsetshire he studied till 1770. When he appeared in London, his extraordinary command of the pianoforte secured him an almost unprecedented success. From 1777 to 1780 he conducted the Italian Opera; in 1781 he visited Paris, Strasburg, Munich, and Vienna, where he engaged in a prolonged musical combat with Mozart before the emperor, the victory being left undecided. Mozart's letters express the verdict that Clementi

was 'a mere mechanician;' but the latter had not then exchanged his brilliant execution for the melodic style of his after performances. He made other visits to the Continent, and amassed an independence in England by teaching; and when much of this was lost in the failure of a musical firm with which he had become connected, he founded the business of manufacturer of pianofortes which is still carried on under the name of his associate, Collard. He died at Evesham, 9th March 1832. He has left over a hundred sonatas, of which sixty are for the pianoforte alone; his 'Op. 2' (composed in his eighteenth year) is considered the model of all modern pianoforte sonatas. Of his other works, the *Gradus ad Parnassum* (1817) is a splendid series of 100 studies, 'on which to this day the art of solid piano-playing rests.'

Cleome'des, author of a Greek treatise, in two books, *On the Circular Theory of the Heavenly Bodies*, which sets forth the Stoic theory of the universe, and which is remarkable as containing, amid much error and ignorance, several truths of modern science—such as the spherical shape of the earth. Nothing is known definitely regarding his life, but it seems most probable that he flourished in the 2d century A.D. Editions of his treatise are those of Bake (Leyden, 1820) and Schmidt (Leip. 1831).

Cleon, a famous Athenian demagogue in the time of the Peloponnesian war, for about six years the leader of the party opposed to peace. Originally a tanner, he gradually abandoned his business, and became the champion of popular rights, a position for which his fluent speech and loud voice fitted him admirably. He first became prominent about 427 B.C. by his advocating the putting to death of the Mytilenean prisoners, but his first great success was the reduction of the island of Sphacteria, in which a Lacedæmonian force had long held out. It is by no means clear how far this exploit was not really due to the skilful dispositions of his colleague Demosthenes, but Cleon himself was highly elated with his success, and many of his countrymen must have credited him with military genius, for in 422 he was sent to oppose Brasidas, the great Spartan general, in Macedonia and Thrace. But for this task the demagogue was insufficient, and he only saved his character by falling in the battle fought under the walls of Amphipolis.

Our picture of Cleon has had the misfortune to have been painted in unfavourable colours by such masters as Thucydides and Aristophanes; and, as Grote has pointed out, it should be remembered that the great historian was full of oligarchical prejudices, while we know that Aristophanes girded at other men about whose nobility of character there is no doubt at all. Besides, it appears not unlikely that both owed the demagogue a private grudge; the former for having been banished at Cleon's instance while holding a subordinate command, the latter because Cleon had complained to the senate that in his comedy, *The Babylonians*, Aristophanes had ridiculed his country's policy in the face of foreigners, and that, too, in time of war. Whether just or unjust the picture, Cleon will live in the *Knights* of Aristophanes as the shifty and unscrupulous demagogue, lying and pandering to the mob, which he befools for his own selfish ends. In this comedy he is one of the actual *dramatis personæ*, and this part the author played himself, not being able to find an actor bold enough to take it.

Cleopa'tra, was daughter of the Egyptian king, Ptolemy Auletes, and was born in 69 B.C. By the will of her father, who died in 51, she should have inherited the throne along with her younger

brother, Ptolemy, who was also to be her husband, in accordance with Egyptian custom. But she was expelled from the throne by young Ptolemy's guardians, Pothinus and Achillas, whereupon she retreated into Syria to raise troops, and was just about to return to reassert her rights when the great Cæsar arrived in Egypt in pursuit of Pompey. Her charms quickly touched the susceptible heart of Cæsar, who warmly espoused her cause, and, after the successful issue of the Alexandrine war, in which Ptolemy fell, placed her again upon the throne, this time with, as nominal colleague and husband, a still younger brother, of whom she soon rid herself by poison. Cleopatra bore a son to Cæsar, who was called Cæsarion (afterwards cut off by Augustus), and soon followed her lover to Rome, where she received such honours as were but ill-pleasing to the Roman populace. In the civil war after Cæsar's murder, she hesitated at first which side to take. After the battle of Philippi, Antony summoned her to appear before him at Tarsus in Cilicia, to give account of her conduct. The 'serpent of old Nile' sailed up the river Cydnus to meet him, in a gorgeous galley, arrayed as Venus rising from the sea, and accompanied with all the gorgeous and romantic splendour of the East. She was then in her twenty-eighth year, in the perfection of matured beauty, and that, from her pure descent, almost certainly of the best Greek type, spite of Shakespeare's 'gypsy's lust,' Tennyson's 'swarthy' cheeks, and Gérôme's typical Egyptian features. The splendour of her beauty and her wit so fascinated the amorous heart of Antony that he at once flung away for her sake, duty, a Roman's pride, and at last all his ambition and his life. They spent the next winter at Alexandria, where they steeped their senses in the most delicious revelries of reckless love. Antony, although in the meantime he had returned to Rome to marry Octavia, the sister of Octavianus, soon returned to the arms of Cleopatra, who met him at Laodicea, in Syria (36 B.C.), and accompanied him on his march to the Euphrates. From this time his usual residence was with her at Alexandria, and here he heaped upon her and her children the most extravagant gifts and honours. His infatuated folly cost him all his popularity at Rome, and weakened his energies for the inevitable struggle. It was at Cleopatra's instigation that Antony risked the great naval battle of Actium, and when she fled with sixty ships, he forgot everything else and flung away half the world to follow her. When the conqueror appeared before Alexandria, Cleopatra entered into private negotiations with him for her own security; while Antony, who was at first indignant at her treachery, being told that she had already killed herself, fell upon his sword. Mortally wounded, and learning that the report which he had heard was false, he had himself carried into her presence, and died in her arms. Octavianus, by artifice, now succeeded in making the queen his prisoner. Finding that she could not touch his colder heart, and too proud to endure the thought that her life was spared only to grace her conqueror's triumph at Rome, she took poison, or as it is said, killed herself by causing an asp to bite her bosom (30 B.C.). Her body was buried beside that of Antony, and the good Octavia brought up the twin children she had borne to Antony as if they had been her own.

For Cleopatra, 'age cannot wither her'—the fascination of her beauty and the rare romantic interest of her story defy the touch of time. Helen of Troy and Mary Stuart alone divide with her that sovereignty over the imaginations of men that survives across the centuries. To dramatist, to poet, and to painter, she will continue to be all that she was to Cæsar and to Antony.

Clepsydra (Gr., 'water-clock'), an instrument to measure time by the trickling or escape of water. In Babylonia, India, and Egypt, the clepsydra was used from before the dawn of history, especially in astronomical observations. A Hindu form of it was that of a copper basin put to float in a vessel, so that by the gradual influx of water through an aperture beneath, it should sink in a certain time. A more common type is that referred to by Greek and Latin writers, which resembled the modern sand-glass, and was used in courts of law to limit the length of the pleadings. Julius Cæsar (*Com. de Bell. Gall.*, lib. v. 13) speaks of measuring time in Britain 'by accurate water-measures,' and some commentators infer that the clepsydra was used by the Britons. More probably, however, it was brought by the Romans, being regularly used in their armies for allotting out the three hours' watches. Pliny ascribes the invention of the clepsydra to Scipio Nasica, but he, no doubt, merely introduced it from Alexandria or Greece, where it had already been greatly improved and perfected.

The general form of the clepsydra consisted essentially of a float which slowly rose by the trickling of water from above through a small hole in a plate of metal. As the float rose it pointed to a scale of hours at the side of the water-vessel, or, in the more elaborate forms, moved a wheel by means of a ratchet, and thus turned a hand on a dial. The first great difficulty was to secure a constant and uniform supply of water. This was well and simply done by using an intermediate cistern, so that, by means of a waste-pipe near the surface, the water always remained at the same level, even when the amount poured in exceeded the average.

There remained a much greater difficulty, arising from a fact often overlooked—viz. that by the Greek and Roman calendar the *hour* was not a fixed space of time, being very much longer in summer than in winter. A *day* meant the interval from sunrise to sunset, and an hour being the twelfth part of it was by no means so simple and measurable a magnitude as the unit of time shown on our modern dials. The problem of measuring the hour, thus varying through the year, was solved by Ctesibius of Alexandria, who invented an elaborate self-adjusting mechanism.—Clepsydra was also the name given to an ancient musical instrument, a hydraulic or water organ, described by Athenæus.

Clerc, JEAN LE. See LE CLERC.

Clerestory, an upper row of windows rising clear above the adjoining parts of the building, but more probably so named as admitting *clearness* or light. The term is particularly applied to the windows in the upper part of the central nave of churches (see GOTHIC ARCHITECTURE; and for an illustration, the article BRISTOL). This mode of lighting was also in use among the Romans. See BASILICA.

Clergy (Gr. *klēros*, 'a lot, an inheritance'). The word *clēros* occurs in the Septuagint as the equivalent of the Hebrew *nachalati*, 'an inheritance,' applied to the Jewish nation generally as peculiarly the divine heritage (Deut. iv. 20; ix. 29), and to the Levitical office specifically, as a 'spiritual' heritage, distinguished from the temporal possessions of the other tribes (Deut. x. 9; xviii. 1-2). In the New Testament it is found in cognate senses applied to the Christian body or its several congregations (1 Peter, v. 3, where the word is plural), and to the apostolic office (Acts, i. 17, 25). Hence the term was very generally applied to the ministers of the Christian religion, as holders of an allotted office, in contradistinction to the

Laity (q.v.). This use of the term is very ancient, being found in Clement of Alexandria (*De Divite. Servando*, 48) and Tertullian (*De Monog.* 12), and appears to have gradually become prevalent, as the ministers of religion more and more exclusively, instead of the members of the Christian church generally, began to be regarded as God's 'heritage' and 'priesthood' (1 Peter, ii. 9), consecrated to him, and peculiarly his. The distinction between the clergy and the laity became more marked through the multiplication of offices and titles among the clergy, the ascription to them of a place in the Christian church similar to that of the priests and Levites in the Jewish Church, with peculiar rights and privileges (which occurs as early as Clement of Rome, *Ep. ad. Corinth.* i. 40), their assumption of a peculiar dress and of official insignia, the growth of monastic institutions, and the introduction of celibacy. In harmony with the notions on which this distinction is founded, is that of an indelible or almost indelible character derived from ordination, so that a renunciation of the clerical office is either viewed as an impossibility, or a sort of apostasy. These notions in their highest degree belong to the Church of Rome. In the Protestant churches, the distinction between clergy and laity is much less wide; and although the same terms are often used, it is rather conventionally than in their full signification. The employment of official robes by the clergy preceded their assumption of a peculiar ordinary dress (indeed, for the most part, there was no direct adoption of a special garb for ordinary occasions, but the clergy did not change their fashions as the laity did, and continued to wear attire, such as the cassock, which was once commonly worn by all persons, but was discarded by the laity), and is not so intimately connected with any peculiar pretensions.

Among the privileges accorded to the clergy by the Roman emperors, and in the middle ages, was exemption from civil offices; among the rights asserted by them, and which caused much dispute, was exemption from lay-jurisdiction, even in cases of felony. With the revival of the Western Empire by Charlemagne, the clergy became one of the Estates of the empire, and the bishops were given baronial rank, and entitled to sit along with the temporal nobles in the imperial Diets. This institution survived the break-up of the Carolingian empire, and prevailed in several parts of Europe, very noticeably in France until the Revolution. In England the clergy are still technically and constitutionally one of the three Estates of the realm, and taxed themselves in their convocations as late as 1663. The bishops who sit in the House of Lords do so in virtue of baronies annexed to their sees, but not as prelates of the church, and it was held by parliament in Henry VIII.'s time, and later by Coke, that the right of session in convocation made the clergy of the second order ineligible to sit in the House of Commons. But the point remained doubtful till the Act 41 Geo. III. chap. 63, sec. 4 definitely excluded clerks in holy orders from sitting there, under a penalty of £500 per day if so sitting or voting. Those only who have formally relinquished the clerical office can sit, in virtue of the Clerical Disabilities Act of 1870. The clergy were distinguished into the *higher clergy* and the *lower clergy*, that is, those in the 'major orders' of bishop, priest, and deacon (and, since the 13th century, sub-deacon), or those in the 'minor orders' of acolytes, lectors, exorcists, &c. The term *Secular Clergy* is the designation of priests of the Latin and Greek churches who do not follow any religious rule (*regula*), but have the care of parishes. Monks who are in holy orders are designated *Regular*

Clergy. See BENEFIT OF CLERGY, ORDERS, BISHOP, PRIEST, RECTOR, &c.

Clergyman's Sore Throat. See THROAT.

Clericus. See LE CLERIC.

Clerk (Lat. *clericus*), properly a clergyman; also, in old usage, a scholar; an officer attached to courts and corporations, who keeps the records; a lawyer's assistant; a booking or railway clerk; and in the United States, a shopman.

The PARISH CLERK is an official in the Church of England, who leads the responses in a congregation, and assists in the services of public worship, at funerals, &c. There is usually one in each parish. In cathedrals and collegiate churches there are several of these lay-clerks; and in some cases they form a corporate body, having a common estate, besides payments from the chapter. Before the Reformation, the duties of parish clerk were always discharged by clergymen in minor orders.

Clerk, JOHN, of Eldin, writer on naval tactics, was born in 1728, the seventh son of the antiquary, Sir John Clerk of Penicuik, Midlothian (1684-1755). He prospered as an Edinburgh merchant, and by 1773 purchased the small estate of Eldin at Lasswade, where he devoted himself to etching, to geology, and to studying deeply both the theory and practice of naval tactics. In 1779 he communicated to his friends a new manœuvre for 'breaking the enemy's line' in a naval battle; and during a visit to London the following year, he claimed to have had some conferences on the subject with naval officers, among whom was Sir Charles Douglas, Lord Rodney's captain of the fleet in the memorable action of April 12, 1782, when the experiment was tried for the first time, and a decisive victory gained over the French. In 1782 Clerk printed 50 copies of his *Essay on Naval Tactics*, for private distribution among his friends. It was reprinted and published in 1790; three parts were added in 1797; and the work was republished entire in 1804, with a preface explaining the origin of his discoveries. Clerk died May 10, 1812.—His son, JOHN CLERK (1757-1832), was raised to the Scottish bench in 1823, when he assumed the judicial title of Lord Eldin.

Clerkenwell, a London parish, lying within the parliamentary borough of Finsbury, and due north of St Paul's. It is largely inhabited by watchmakers, goldsmiths, and opticians. The Fenian attempt to blow up Clerkenwell prison took place 13th December 1867. Pop. (1881) 69,076.

Clerk-Maxwell. See MAXWELL.

Clermont (in the middle ages, *Clarus Mons*, or *Clarimontium*) is the name of several towns in France. The most important are: (1) CLERMONT, in the department of Oise, 41 miles N. of Paris by rail, with a large hospital and a prison for women. Pop. (1886) 5529.—(2) CLERMONT-FERRAND, the capital of the department of Puy-de-Dôme (the *Augustonemetum* of the Romans, in the country of the Arverni), which is finely situated on a gentle elevation between the rivers Beud and Allier, 135 miles S. of Paris by rail. Among the principal buildings are the old Gothic cathedral, built of dark lava from a neighbouring range of extinct volcanoes; the fine church of Notre Dame, where Peter the Hermit preached the first Crusade; the handsome Palais des Facultés; and the government buildings, formerly a convent (1250). The town is the seat of a medical and a theological college, technical schools, and several scientific bodies, and has a public library with 40,000 volumes. The streets, with the exception of a number of fine squares, are narrow, tortuous, and steep. The chief manufactures are candied fruits, wax matches, chemicals, linen, rope, lace, and machines, and there is

an extensive traffic in the produce of the district, and in the transit trade between Paris and the south of France. There are several mineral springs in the town, of which the iron spring of St Alyre (65° F.) has formed by deposits in the course of ages two natural bridges. The bishopric of Clermont was founded in 253; and seven ecclesiastical councils were held here during the middle ages, the most remarkable of which was that in 1095, at which the first Crusade was instituted by Urban II. A statue has been erected to Pascal, who, as well as Gregory of Tours, was a native of Clermont. Pop. (1872) 32,963; (1886) 41,740.—(3) CLERMONT L'HÉRAULT, 33 miles W. of Montpellier by rail, with manufactures of leather and of cloth for the army. Pop. 4929.

Clevedon, a pleasant Somersetshire watering-place, on the Bristol Channel, 12 miles by road but 16 by rail WSW. of Bristol. The historian Hallam, and Arthur, his son, lie in the old parish church; Coleridge lived a while here at Myrtle Cottage (1795); and Clevedon Court, a mediæval mansion of singular beauty, though much damaged by fire in 1882, is the 'Castlewood' of Thackeray's *Esmond*. Pop. of parish (1851) 1905; (1881) 4869.

Cleveland, a wild mountainous district, with some picturesque fertile valleys, forming the east part of the N. Riding of Yorkshire between Whitby and the Tees. In the south the hills rise 1300 to 1850 feet. An extraordinary change has been wrought in the aspect of the country by a rich discovery of ironstone in the Cleveland hills; since 1851, lonely hamlets have become populous towns. The ironstone is chiefly an argillaceous carbonate, inferior in quality to the ironstone of the coal-measures. See MIDDLESBOROUGH, IRON. The title of Duchess of Cleveland was conferred in 1670 by Charles II. on his mistress, Barbara Villiers (see CHARLES II.), and her eldest son (Fitzroy) was first duke. In 1827 the title of Marquis of Cleveland was bestowed on William Henry Vane, Earl of Darlington (whose grandfather married a descendant of the first duke); he became duke in 1833.

Cleveland, the second city of Ohio in population and general importance, and the eleventh, in 1880, in the United States, is situated at the mouth of the Cuyahoga River, on the south shore of Lake Erie, 255 miles by rail NE. of Cincinnati, 183 SW. of Buffalo, and 350 E. of Chicago. The city is built mainly upon a plain from 60 to 150 feet above the lake, and is divided into two great divisions, the east and west sides, by the tortuous valley of the Cuyahoga. The 'flats,' about half a mile wide, along the river are occupied by vast lumber-yards, numerous factories, iron, flour, and other mills, coal-yards, ore docks, ship-yards, &c. A wide and massive viaduct, 3211 feet long, constructed mainly of stone, and completed in 1878 at the cost of \$2,250,000, crosses the valley at the height of 50 to 70 feet; and another viaduct of iron (1888), 100 feet above the river and 3931 feet long, makes a second broad level highway between the two divisions of the city. The river is the harbour, and is spanned by numerous bridges. An outer harbour, safe and commodious, is completed by the construction of an immense United States breakwater, about 2 miles long and half a mile from the shore, opposite the mouth of the river, where there is a large opening for vessels. The business centre of Cleveland extends east from the lower part of the river-valley, for three-fourths of a mile along Superior Street, which is 132 feet wide, and the chief shopping thoroughfare. It embraces several parallel and intersecting streets. In this district is the Public Square, 10 acres in area. The custom-

house and post-office, a large stone structure, is situated on the east side of the square, upon which front also a court-house, the fine old 'Stone' (first Presbyterian) Church, a theatre, an hotel, banks, and many business blocks. This attractive breathing spot contains fountains, a stone speakers' stand for public meetings, and a statue of Commodore Perry, the hero of the battle of Lake Erie in 1813. From the south-east corner of the square, Euclid Avenue, the most famous street in the city, and, according to Bayard Taylor and other travellers, the most beautiful in the world, extends nearly east through the best residence quarter of Cleveland. Four and a half miles from the square it passes Wade Park, a beautiful tract of about 65 acres, containing a lake for boating, a deer paddock, fountains, and groves of noble forest-trees.

A mile farther east, just beyond the city limits, is Lake View Cemetery, one of the finest in the country. Here, on a commanding site, 250 feet above Lake Erie, stands the stone monument to the late President Garfield, built by subscription at a cost of about \$130,000. The monument is 125 feet high, and surmounts the president's grave. Euclid Avenue is lined with stately mansions upon a gentle eminence, 200 to 500 feet from the Avenue, in a park-like stretch of shade-trees, smooth lawns, flowers, shrubbery, and winding walks and drive-ways. The same wealth of gardens and shade-trees is noticeable in a less degree throughout the 'Forest City,' except in the poorest quarters. Few houses are built in blocks, and tenements are virtually unknown. At least 20,000 families, it is believed, own the houses in which they live, and the area of the city, 26½ sq. m., is about 20 per cent. greater than that of Manhattan Island, on which New York is mostly built. About 19½ sq. m. lie east of the river and 6½ miles west. The soil is light and sandy, the drainage excellent, and the water supplied from Lake Erie by a tunnel, two pumping stations and standpipes, and two large reservoirs, is pure and abundant. The climate is temperate, the average yearly rainfall being 37·6 inches, and the mean annual temperature 50° F. Naturally the death-rate is low, averaging about 18 in the thousand of population. Cleveland has a music-hall capable of seating 5000 persons, 4 fine theatres and 6 of less importance, 150 churches, 8 colleges—3 of which are medical schools—7 hospitals, and many asylums and other benevolent institutions. There are two large circulating libraries, one, containing about 52,000 volumes, being free. The schools number about 100; and 60 periodicals, daily, tri-weekly, weekly, and monthly, are published in the city. Cleveland's rapid growth is due mainly to the fact that nowhere else can the rich iron ores of Lake Superior, the coal of Northern Ohio, and the limestone of the Lake Erie islands, be brought together so cheaply. The chief industries of the city are the various manufactures of iron, including steel rails, forgings, wire, bridges, steel and iron ships, engines, boilers, nails, screws, sewing-machines, agricultural implements and machinery of all kinds, the refining of petroleum, wood-work, and other manufactures of endless variety. In 1880 the value of manufactured products was \$48,600,000, the number of persons employed 21,700, and the capital invested \$19,430,000. All of these figures must be increased at least 50 per cent. to approximate existing facts.

In 1887 the vessel tonnage constructed in Cleveland, nearly all in steamships of 1500 to 2500 tons burden, exceeded that built in the entire state of Maine. The city has a commanding commercial situation, due, primarily, to its position at the north terminus of the Ohio Canal, connecting Lake Erie with the Ohio River at the mouth of the Scioto. The start obtained when the canal was opened in

1834 has been maintained. Seven railroads terminate in the city, and two pass through it from east to west. Cleveland's lake commerce is very great, the total tonnage entered and cleared in 1887 exceeding 3,000,000 tons. Cleveland is the greatest iron ore receiving point in America, one of the largest lumber markets in the country, and the mercantile centre of an extensive and productive region. In 1796 a party under General Moses Cleveland laid out the site of a town where Cleveland now stands, and in 1830 the population of the town was 1076. In 1836 the city of Cleveland was incorporated. Since then its growth has been very rapid. In 1840 the Federal census showed a population of 6071; (1850) 17,034; (1860) 43,417; (1870) 92,829; and (1880) 160,146. A police census in 1886 returned the number of inhabitants at 214,013, and the population in 1889 was at least 240,000.

Cleveland, GROVER, the twenty-second president of the United States, was born at Caldwell, New Jersey, March 18, 1837, the son of a Presbyterian minister. In early life he removed to the state of New York. In 1859 he was admitted to the bar, and began the practice of law at Buffalo. From 1863 to 1866 he was assistant district attorney for Erie county, and in 1870 was chosen sheriff. After filling the office of mayor of Buffalo, he was, in 1882, elected governor of New York by an unexampled majority of more than 190,000 votes. His course as governor was approved by the best people of all parties. In 1884 he was nominated by the Democrats for the chief magistracy of the United States. The canvass which followed was one of extreme earnestness and excitement. Cleveland received 219 electoral votes (Blaine, the Republican candidate, securing 182); and the returns of the popular vote also gave him a plurality. He took his seat as president in 1885. In a unique and forcible message to congress in December 1887 regarding the reduction of the great surplus in the national treasury, he strongly advised a careful readjustment of the tariff charges on certain manufactured articles of import, and the admission duty-free of some of the raw materials of manufacture—a position which led to a well-defined issue between the two political parties. Protectionists classed the president's message as a free-trade document, but this was denied by the Democrats, and its doctrines were adopted as the basis of the Democratic platform at the convention of that party in 1888, when Mr Cleveland was unanimously nominated for re-election to the presidency. In the following August, on the rejection of the proposed Fisheries Treaty with Canada by the Republican majority in the senate, the president sent a message to congress, declaring a policy of 'retaliation' against Canada now necessary, and asking for powers to put an end to the privilege, formerly enjoyed by the Canadians, of transporting goods in bond across the territory of the United States. In October, in consequence of Lord Sackville, the British minister at Washington, responding to an application from a naturalised American citizen of English birth, who had asked for advice on the pending election, the president demanded the ambassador's recall. At the election in November Cleveland was defeated by the Republican candidate, General Harrison, who received 233 electoral votes, as against 168 cast for Cleveland.

Cleveland, JOHN, a cavalier poet, born at Loughborough, in Leicestershire, in June 1613, the son of a needy clergyman, who was ousted by the parliament from the living of Hinckley in 1644. In 1627 he was admitted at Christ's College, Cambridge, graduated B.A. four years later, and

then migrated to St John's College, where he was elected to a fellowship in 1634, and lived nine years 'the delight and ornament of St John's society.' Here he studied both law and physic. Cleveland vigorously opposed Cromwell's election to the Long Parliament for Cambridge, and was for his loyalty ejected from his fellowship by the parliament in 1644. He betook himself to the king's army, was popular among the cavaliers, and was appointed 'judge-advocate' at Newark, but was obliged to surrender with the garrison. His indignation at the Scotch army for handing over the king to the parliamentarians he expressed in some stinging verses, which, however, are too violent to be really strong. Henceforward Cleveland lived upon the hospitality of his partisans, and was forced to keep his wit in check. In 1655 he was arrested at Norwich, but was soon released by command of Cromwell, whose magnanimous spirit could admire the courageous manliness of the poor poet's letter addressed to him. In 1656 he published a small volume containing thirty-six loyal poems, consisting of elegies upon Charles I., Strafford, Laud, and Edward King, the subject of Milton's *Lycidas*, also some stinging satires. Cleveland now went to live at Gray's Inn, where he soon after died, April 29, 1658. In the year 1677 was published, with a short account of the author's life, *Cleveland's Viridities, or Cleveland's Genuine Poems, Orations, Epistles, &c.* Cleveland undoubtedly exercised a strong influence upon the greater genius of Butler. Thomas Fuller commends him as 'a general artist, pure latinist, exquisite orator, and eminent poet. His epithets were pregnant with metaphysics, carrying in them a difficult plainness, difficult at the hearing, plain at the considering thereof.'

Cleves (Ger. *Kleve*, Dutch *Kleeff*), a town of Rhenish Prussia, 48 miles NW. of Düsseldorf. It is situated on three gentle elevations, about 24 miles from the Rhine, with which it communicates by canal, in the midst of a rich and beautiful country. It is well built, in the Dutch fashion, and surrounded by walls. The fine old castle, known as the Schwanenburg, partly built on a commanding rock, is the reputed scene of the legend of the Knight of the Swan, made familiar by Wagner's opera of *Lohengrin*. Anne of Cleves, fourth wife of Henry VIII., was born in this castle. In the collegiate church, which dates from the 14th century, are some good monuments to the counts and dukes of Cleves. Cleves has manufactures of cotton and leather goods, tobacco, &c. Pop. (1885) 10,170. Cleves was anciently the capital of a duchy (a countship until 1416) extending along both banks of the Rhine, which passed by inheritance in 1609 to Brandenburg.

Clew Bay, an inlet of the Atlantic, on the west coast of County Mayo, Ireland, about 15 miles long by 9 broad. The upper part of the bay contains an archipelago of fertile and cultivated islets; and at the entrance of the bay is Clare Island (3949 acres; pop. 62), which, as well as Inishgort (27 acres; pop. 23), has a lighthouse.

Cliché (Fr.), the impression made by a die in any soft metal. It is the proof of a medallist's or die-sinker's work, by which they judge of the effect, and ascertain the stage of progress which they have reached before the die is hardened. The same term is applied by the French to electrotype casts from wood-engravings.

Clichy, a town of France, on the Seine, to the north-west of Paris, of which it forms a suburb. It has numerous manufactories, especially of chemicals and catgut, and is much affected by washerwomen. Pop. (1872) 14,599; (1886) 26,741.

Client. See AGENT AND CLIENT. See also PRINCIPAL AND AGENT, PATRON.

Clifford, a family descended from Walter, Roger Fitzpounce's son, who by marriage, prior to 1138, acquired Clifford Castle on the Wye, 17 miles W. of Hereford, and who thence assumed the surname Clifford. He was the father of Fair Rosamond, Henry II.'s mistress, who seems to have died about 1176, and to have been buried at Godstow Nunnery, near Oxford. The legend of her murder by Queen Eleanor appears first in the 14th century; the Woodstock maze, the clue, the dagger, and the poisoned bowl belong to a yet later age. Among Walter's descendants were the soldier-judge Roger de Clifford, who by marriage with Isabella de Vipont got Brongham Castle in Westmoreland (circa 1270); John (1435-61), the savage Lancastrian; Henry (1455-1523), the 'shepherd lord'; Henry (1493-1542), fifteenth Lord Clifford and first Earl of Cumberland; George, third earl (1558-1605), naval commander; and Henry, fifth and last earl (1591-1643). To a cadet branch belonged Thomas Clifford (1630-73), a Catholic member of the Cabal, who in 1672 was created Lord Clifford of Chudleigh.

Clifford, WILLIAM KINGDON, F.R.S., one of the foremost mathematicians of his time, was born at Exeter, May 4, 1845. He was educated at a school in his native town, at King's College, London, and at Trinity College, Cambridge. While at Trinity he did not confine himself to examination subjects, but read largely in the great mathematical writers, and came out second Wrangler in 1867, next year being elected a fellow of his college. At this time, while excelling in gymnastics, he would also solve and propound problems in the pages of the *Educational Times*, and could discuss with ease complicated theorems of solid geometry without the aid of paper or diagram. A High-Churchman at first (though on unconventional speculative grounds), Clifford soon after taking his degree threw off all dogmatic restraints, and discussed the fundamental questions of the philosophy of religion with complete independence. In August 1871 he was elected to the chair of Mathematics and Mechanics at University College, London, which post he retained until his untimely death at Madeira, March 3, 1879. Clifford first established his reputation as an original thinker with the faculty of expressing scientific thought in plain and simple language by a Friday evening discourse at the Royal Institution, *On Some of the Conditions of Mental Development*. He was a valued member of the London Mathematical Society, contributing to the *Proceedings*; for a time he acted as secretary, and afterwards vice-president of the Mathematical and Physical section of the British Association; he also lectured to the Sunday Lecture Society on various physical and philosophical subjects. The versatility of his mind for philosophical and scientific discussion was further shown by his varied contributions to periodical literature. Clifford issued in his lifetime the first part of *Elements of Dynamics* (1878). A further portion, edited by Mr R. Tucker, was published in 1887. A work on the *Common Sense of the Exact Sciences*, which Clifford left unfinished, was completed and edited by Professor Karl Pearson in 1885. A selection from his *Mathematical Papers* appeared in 1881, and a series of lectures on *Seeing and Thinking* in 1879. Clifford's general scientific and philosophical writings are collected, with a prefatory memoir, in *Lectures and Essays*, edited by L. Stephen and F. Pollock, 1879 (2 vols.; 2d ed. in 1 vol. 1886).—Mrs Clifford (*née* Lucy Lane) has

published a really striking novel, or rather tragedy, *Mrs Keith's Crime* (1885), and two books for young children of quite unusual interest, *Anyhow Stories* (1884), and *Very Short Stories and Verses for Children* (1886).

Clifton. See BRISTOL.

Clifton, a town and port of entry of Ontario, on the Niagara River, about 2 miles below the Falls. Here the Great Western Railway of Canada connects with the New York Central, the trains crossing the river on a noble suspension bridge, 800 feet long and 240 above the water. Pop. 1610.

Climacteric Years (from Gr. *klimaktēr*, 'the step of a stair or ladder,' *klimax*). It was long believed that certain years in the life of man had a peculiar significance to him, and were the critical points, as it were, of his health and fortunes. The mystical number 7 and its multiples with odd numbers (e.g. 35, 49) constituted crises of this kind. The most important of all was the 63d year, called, by way of eminence, the 'climacteric year' or 'grand climacter,' which was supposed to be fatal to most men; its influence being attributed to the fact that it is the multiple of the two mystical numbers 7 and 9. An actual 'change of life' (Fr. *âge critique*) in woman is marked by the cessation of menstruation, usually between the 48th and 52d years. Astrologers called any period which an evil conjunction marked as threatening, a *climacteric time*.

Climate (from the Greek *klima*, 'a slope or inclination,' afterwards applied to a tract of country, with reference to its supposed inclination to the pole, and the effect of the obliquity of the sun's rays upon the temperature), a term now employed as including not merely the conditions of a place or country with regard to temperature, but also its meteorological conditions generally, in so far as these exercise an influence on the animal and vegetable kingdoms. The effect of the sun's rays is greatest where they fall perpendicularly on the surface of the earth, and diminishes as their obliquity increases; the surface which receives any given amount of the sun's rays increasing with their increased obliquity, as *a'b'* is greater than *ab* in the annexed figure; whilst

at the same time the oblique rays being subjected to the influence of a greater number of particles of the atmosphere, as *c'a'* is longer than *ca*, a greater amount of their heat is absorbed before they reach the surface of the earth at all. The greater or smaller extent of surface receiving a certain amount of heat, also makes important differences to arise from *exposure* by slope towards the equator or towards the nearest pole. *Elevation* is a most important cause of differences of climate. As we ascend from the level of the sea to the greatest mountain altitudes, the temperature gradually diminishes, and we ultimately reach a region of perpetual snow, as in approaching the poles. The progressive diminution of the temperature is, however, affected by many causes, so that the line of perpetual snow is far from being at the same elevation in all places of the same latitude. Thus the snow-line on the southern side of the Himalayas is depressed by the heavy rainfall brought by the winds from the Indian Ocean; and that on the northern side is elevated by the extreme drought and summer heat in the vast

tablelands of Central Asia, thus causing active evaporation from the snow-fields; so that the difference between the two is not less than 4000 feet in favour of the northern side of the mountain-ranges; and Humboldt says, 'millions of men of Tibetan origin occupy populous towns in a country where fields and towns would, during the whole year, have been buried in snow, if these tablelands had been less continuous and less extensive.'

As the actual temperature of the atmosphere depends not so much upon the direct rays of the sun as upon the radiation from the heated surface of the earth, the diversities in the character of that surface are productive of great effects in modifying climate. A sandy desert, a tract of country clothed with luxuriant vegetation, and an expanse of water, absorb and radiate heat in very different degrees. A newly ploughed field both absorbs and radiates heat much more rapidly than a field covered with grass. A sandy desert heats the atmosphere above it much more than either a fertile tract or a watery expanse, whilst a watery expanse only slightly raises the temperature; but, on the other hand, the desert cools sooner by terrestrial radiation; whilst the heat absorbed by the water being diffused through a larger mass, owing to the depth to which solar radiation penetrates and to vertical as well as horizontal currents generated by the winds to great depths, the influence of the ocean, of seas, and of great lakes, is very powerful in maintaining a greater equableness in the temperature of the air. Thus maritime places, and particularly islands and peninsulas, have a more equal temperature, with less diversity of the extremes of summer and winter, than more inland or continental places otherwise similarly situated. The effect of the sea is modified by many circumstances, and particularly by currents, of which the Gulf Stream (q.v.) affords a notable instance, the heated water conveyed by it and by the general surface-flow north-eastwards of the waters of the Atlantic, from the equatorial to the polar regions, having a great influence on the climate, particularly of the north-west of Europe. Over the world generally, atmospheric currents or prevailing winds must be regarded as exercising even a greater influence on climate than oceanic currents. The quantity of rain or snow that falls in the course of a year, and the times and manner of its falling, are circumstances which have the greatest possible effect on climate; these being in their turn much influenced by the distribution of land and water, and by the character and elevation of the surface of the land, according as the mountain-ranges lie across or in the line of the rain-bringing wind.

The relations of climate to vegetation are generally determined less by the mean annual temperature than by the relative duration of summer and of winter. Thus maize, which may be mentioned as an important example, succeeds well in climates of which the winter-cold is severe, the summer season alone being sufficient for its whole life; whilst, on the other hand, such plants as fuchsias, some kinds of laurel, and even the common hawthorn, which succeed well enough where maize would scarcely put forth an ear, would perish from the colder winters of countries where it is profitably cultivated. The polar limit of particular species of animals, except those which hibernate, is generally determined by the degree of winter-cold which they can bear without injury.

Bogs and marshes exercise an unfavourable influence on climate, cooling the air and generating fogs, as do clay-soils also to some extent, through their retentiveness of moisture; whilst marshes of some kinds, and in some situations, abound in malarious and other exhalations very unfavourable to health. Similar remarks apply to large tracts of forest.

The clearing, drainage, and cultivation of land have generally favourable effects on climate; although plantations are often beneficial for shelter, and a too complete removal of natural forests may prevent the deposition of moisture from the atmosphere to such a degree as to cause droughts, a result stated to be exemplified in some of the smaller West India Islands, and the tendency to which is said to be manifested on a great scale in the eastern part of the continent of North America.

The important and difficult subject of climate will be found further elucidated in some of the principal geographical articles (ASIA, &c.), and in the articles ATMOSPHERE, GEOGRAPHICAL DISTRIBUTION, GLACIAL PERIOD, HEALTH RESORTS, HYGROMETRY, METEOROLOGY, MONSOONS, PLEISTOCENE, RAIN, SEASONS, SNOW-LINE, STORMS, TEMPERATURE, TRADE-WINDS, WEATHER, WIND. See also Ramsay, *Bibliography and Index of Climate* (1888), and the works named under CROLL.

Climax (Gr., 'a stair'), in Rhetoric, that artifice which consists in placing before the mind of the reader or hearer a series of propositions or objects so arranged that the least forcible strikes it first, and the others rise by successive gradations in impressiveness. See the example in 1 Sam. iv. 17.

Climbers (*Scansores*), an old-fashioned popular title for several orders of birds whose feet are mainly adapted for climbing. In many cases two toes are turned forward, and two backward; or it may be that one permanently turned backward is joined in branch grasping by another reversed for the nonce. Parrots (*Psittaci*), cuckoos (*Coccygomorpha*), woodpeckers (*Picariæ*), &c. are included under this wide and somewhat inexact title.

Climbing Perch (*Anabas scandens*), a bony fish in the Acanthopteri division, famous for its peculiar clambering habits. It is a native of rivers and ponds in most parts of the East Indies. It is about six inches long, and in general form somewhat resembles a perch. That this fish climbs trees, has been asserted by observers whose veracity and accuracy cannot easily be questioned; yet others, who have enjoyed ample opportunity of observation, express great doubt concerning this habit. According to circumstantial accounts, the fish suspends itself by its spiny gill-covers, and by fixing its anal fin in cavities of the bark, urges its way upwards by distending and contracting its body. There is no doubt that it often leaves pools when they are in danger of being dried up, and travels in search of water. Though these fish are sometimes

Climbing Perch.

compelled in their distress to travel by day, and have been met in the glare of noon toiling along a dusty road, their migrations are generally performed at night or in early morning, whilst the grass is still wet with dew. This restless fish is aided in its peregrinations out of water by an accessory labyrinthine respiratory cavity, in which water may be retained for a considerable time. Climbing perches are plentiful in the Ganges, and the boatmen have been known to keep them for five or six days in an earthen pot without water, using

daily what they wanted, and finding them as lively as when just caught. Some related forms, such as the walking fish (*Ophiocephalus*), exhibit to a less marked degree the same power of living out of water. Closely related also is the Chinese Macropod, not unfrequently kept for its beauty in aquaria. Many of the genera make nests for the eggs, over which the males frequently keep guard.

Climbing Plants, or **CLIMBERS**, are, in the most extensive and popular sense of the term, those plants which, having weak stems, seek support from other objects, chiefly from other plants, in order to ascend from the ground. This, however, is accomplished in very different ways. Some climb by means of small root-like processes growing from the stem, as the ivy; others by means of hooks (e.g. *Cleavers*, q.v.); others again twining round their support—e.g. *hop*, *convolvulus*, &c.; and others, the most evolved, by help of sensitive organs, which are branches or leaves or leaf-stalks more or less modified. The subject of climbing plants has been worked out with peculiar fullness and interest in Mr Darwin's classical *Climbing Plants*; but its main facts and theories may be more profitably discussed under the general head of plant-movements. See **PLANTS** (MOVEMENTS OF), and special articles—e.g. **TENDRIL**, **LIANA**.

Clinical Medicine (Gr. *klinē*, 'a bed') is that department of the art which is occupied with the investigation of diseases at the bedside of the sick; and a clinical lecture is one delivered to students there. So with clinical surgery. Clinical baptism is baptism administered to sick or dying persons on their sick-bed; a clinical convert is one converted on his death-bed.

Clinker, the name given to the scales or globules of black oxide of iron, obtained from red-hot iron under the blows of a hammer. The same term is applied to the slags of iron-furnaces. By geologists the cindery-like masses which form the crust of some lava-flows are termed clinkers.

Clinker-built, or **CLENCHEE-BUILT**. See **BOAT**.

Clinkstone, or **PHONOLITE**, is a greenish gray or brownish compact or very finely crystalline igneous rock, remarkable for its tendency to split into slabs, which are now and then thin enough to be used for roofing purposes. This structure is due to the parallel arrangement of plate-like or tabular crystals of sanidine felspar. The slabs give a metallic ring or 'clink' when struck with a hammer, whence its name. Its essential mineral components are sanidine and nepheline, but other minerals, such as augite or hornblende, leucite and magnetite, are usually present. The rock has often a porphyritic structure.

Clinometer, an instrument for the purpose of taking the amount of dip or angle of inclination of a stratum. There are various kinds in use, but the simplest consists of a strip of wood upon which is mounted a graduated arc with a pendulum. When this instrument is held horizontally, the pendulum points to zero; when it is held in a slanting position, the pendulum shows the number of degrees that the upper edge or the base of the strip deviates from horizontality. The most useful form of clinometer is that which is combined with a compass—both these instruments being required in geological observations.

Clinton, (1) capital of Clinton county, Iowa, on the Mississippi, which is here crossed by an iron railroad bridge, 4000 feet long, 60 miles SSE. of Dubuque by rail. It has numerous mills, foundries, and factories, and a trade in lumber and grain. Pop. (1870) 6129; (1885) 12,012.—(2) A town of Massachusetts, on the Nashua River, 45 miles W. of Boston by rail. It has large manufactures of

ginghams and plaids, carpets, combs, and machinery. Pop. (1885) 8945.—(3) A post-village of Oneida county, New York, 9 miles WSW. of Utica, is the seat of Hamilton College (1812), a Presbyterian foundation, with about 180 students, and of several other noteworthy educational institutions. Pop. 1236.

Clinton, a distinguished American family, descended from Charles Clinton, who was born in Ireland in 1690, settled in New York state in 1731, and died there in 1773.—His third son, JAMES, born in 1736, served with distinction against the French, and as brigadier-general took part in several operations during the War of Independence. He died in 1812.—His brother, GEORGE, born in 1739, studied law, and from 1768 sat in the New York assembly; in 1775 he was sent as a delegate to the second Continental Congress, and in 1776 he was appointed general of militia, serving against Sir Henry Clinton on the Hudson. In 1777 he was chosen first governor of New York, to which post he was re-elected from 1780 to 1795, and in 1801; and to him was due the first conception of the Erie Canal. In 1804 he was chosen vice-president of the United States, and in that office he died at Washington, 20th April 1812.—James's son, DE WITT, born in 1769, was admitted to the New York bar in 1788, and was private secretary to his uncle, then governor, from 1790 to 1795. He sat in the state legislature (1797) and in the state senate (1798-1802); and in 1802 he was elected to the United States senate, but resigned in the same year on being appointed mayor of New York by his uncle. In this office he continued, save for two short intervals, until 1815, holding other appointments at the same time; he was defeated by Madison in the presidential contest of 1812. It was he who pressed the adoption of the Erie Canal scheme; the bill was passed and Clinton elected governor of the state in 1817, and in 1825 he opened the canal. He was several times re-elected in spite of the untiring efforts of his political opponents, and died in office at Albany, 11th February 1828. He published a number of addresses, some literary and historical, which will be found in his *Life* by Campbell (1849).

Clinton, SIR HENRY, British general, born about 1738, was the son of the Hon. George Clinton, colonial governor of Newfoundland, and afterwards of New York. He first entered the New York militia, was gazetted to the Guards in 1751, served with conspicuous gallantry on the Continent, and was promoted colonel in 1762 and major-general in 1772. From 1772 to 1784 he sat in parliament in the interest of his cousin, the Duke of Newcastle. Sent to America in 1775, he fought at Bunker's Hill, and in 1776 was repulsed in an attack on Charleston, but was shortly afterwards knighted for his services under Howe. After Burgoyne's surrender in 1778, Clinton succeeded Howe as commander-in-chief of the forces in North America, which he at once concentrated in New York. In 1780 he captured Charleston and the entire southern army; but after Cornwallis' capitulation at Yorktown in 1781, Clinton resigned his command and returned to England, where in 1783 he published a *Narrative of the campaign*. In 1794 he was appointed governor of Gibraltar, and died there, 23d December 1795. His two sons both rose to be generals in the army and G.C.B.'s, the younger being one of Wellington's favourite officers.

Clinton, HENRY FYNES, a great classical scholar, was born January 14, 1781, at Gamston, in Nottinghamshire. He was educated at Southwell, Westminster, and Christ Church, Oxford, where he graduated B.A. in 1803. He represented Aldborough in parliament from 1806 till 1826. He

died at Welwyn, October 24, 1852. His great works on Greek and Roman chronology are unlikely ever to be superseded or forgotten. These are the *Fasti Hellenici* (1824-34), and *Fasti Romani* (1845-50).

Clinton Group, name given in North America to a subdivision of the Upper Silurian strata.

Clio, in Greek Mythology, the Muse of History and Epic Poetry. She was represented as sitting with a half-opened scroll in her hand, and a casket for holding manuscripts at her feet. See **MUSES**.

Clio, a genus of shell-less pelagic molluscs in the class of Pteropods. They occur in myriad swarms in northern (*C. borealis*) and southern (*C. australis*) seas, and along with such related forms as *Limacina* form the principal part of the food of some species of whales. The whalers rightly call it 'whales' food.' The whale has simply to swim through a shoal with its mouth open to engulf thousands. Clio is a small animal of a spindle-shape, towards an inch in length, with distinct head, bearing six tentacle-like processes, which are sensitive and glandular, and in part used for laying hold of the prey of small animals. It is active in habit, rising to the surface when calm, or as rapidly sinking again. It swims by means of two locomotory expansions of the 'foot.' See **PTEROPODS**.

Clipper is a name familiarly given to a sailing-ship built expressly for speed. Aberdeen was long celebrated for building swift tea-clippers, which since 1860 have been gradually superseded by steamers. The Baltimore clippers were also famous. As to the possible rate of speed, it may be noted that the *Lightning*, built at Boston, U.S., in 1854, during a voyage from Melbourne to Liverpool ran 2550 English miles in one week, or at the rate of about 15½ miles an hour during the whole period.

Clipping the Coin. See **COINING**.

Clitheroe, a municipal borough in Lancashire, on the left bank of the Ribble, 35 miles N. of Manchester, and 225 NNW. of London by rail. It lies on a low eminence of carboniferous limestone, at the base of Pendle Hill, which is 1831 feet high. Clitheroe has cotton and paper mills, and extensive lime-quarries are wrought in the neighbourhood. Its ruined castle, founded by Robert de Lacy in the later part of the 12th century, was dismantled by the parliamentarians in 1649. The free grammar-school dates from 1554. About 4 miles southwest of Clitheroe lies Stonyhurst College (q.v.). Clitheroe has been a borough since about 1280. Till 1832 it returned two members to parliament; till 1885, one. Pop. (1851) 7244; (1881) 10,176. See Whitaker's *History of Whalley and Clitheroe* (1801; 4th ed. 1872-76).

Clive, CAROLINE, novelist, was born in London, 24th June 1801, the daughter of Mr Meysey-Wigley, M.P. for Worcester. In 1840 she married the Rev. Archer Clive; and, for several years a great invalid, she died, through her dress catching fire, at Whitfield, Hereford, 13th July 1873. Between 1840 and 1872 she published eight volumes of poems by 'V.', but she is best known by *Paul Ferroll* (1855), a really strong sensation novel, much superior to *Why Paul Ferroll killed his Wife* (1860).

Clive, KITTY, comic actress, was born in London in 1711, the daughter of William Raftor, a Jacobite lawyer from Kilkenny. She came out at Drury Lane about 1728, and chiefly at Drury Lane she continued to play till 1769, when she quitted the stage, and retired to Twickenham. About 1731 she had married George Clive, a barrister, but they soon parted. She died at Little Strawberry Hill, 6th December 1785. Garrick, Handel, Horace Walpole, and Dr Johnson all liked her, the last

remarking to Boswell that 'in the sprightliness of humour he never had seen her equalled.' And of him she said: 'I love to sit by Dr Johnson; he always entertains me.' See her *Life* by Percy Fitzgerald (1888).

Clive, ROBERT, the creator of our Indian empire, was born at the manor-house of Styche, near Market-Drayton, 20th September 1725. He was the eldest of thirteen children; his father, a lawyer and small landowner, of a very old Shropshire family. The boy was brought up by an uncle near Eccles. There, and at all his four schools—Lostock, Market-Drayton, Merchant Taylors', and Hemel-Hempstead—he proved a much better fighter than scholar, a thorough young dare-devil; and in 1743 he was packed off to India as a writer in the service of 'John Company.' He reached Madras penniless, and the drudgery of his life there moved him to suicide. But the pistol snapped twice, and he flung it from him, exclaiming: 'It appears I am destined for something; I will live.'

The capture of Madras by the French (1746), Clive's escape thence to Fort St David (the scene of his gallant duel with the card-sharper), his share in its defence, in the fruitless siege of Pondicherry (1748), and in the storming of Devikota (1749)—these events bring us up to the August of 1751, and Clive's daring dash upon Arcot. He seized it, and held its enormous citadel for eleven whole weeks against 7000 natives and 120 French soldiers. His own little force was reduced to 80 Englishmen and 120 sepoys (splendid fellows these); but, after a last desperate assault, the siege was raised (14th November), and Clive followed up his success by the victories of Arni and Kaveripak, and the capture of Kovilam and Chingalpat.

In February 1753 he married Margaret Maskelyne, sister to the astronomer, and immediately after sailed with her for England, where he was presented with a diamond-hilted sword, cleared his father's estate from encumbrances, stood for St Michaels, but was unseated, and otherwise got through a very fair fortune.

So in October 1755 he was back in India, and a twelvemonth later was summoned, with Admiral Watson, from Madras, to avenge the atrocity of the Black Hole. Calcutta was soon retaken; Chandernagore, the French settlement, captured; and at Plassey, on 23d June 1757, Clive's 3200 men (two-thirds of them sepoys) encountered Suraj ud Dowlah's 50,000 with 40 to 50 French gunners. The battle took eight hours to win, that truly 'decisive battle of the world.' But its lustre was sullied by the only two blots on Clive's memory. In his dealings with Mir Jaffier, the would-be next nawab of Bengal, he had imposed on a go-between, the merchant Omichand, with a fictitious treaty, to which he had forged his colleague Watson's signature; and now from Mir Jaffier he accepted a present of upwards of £200,000. Both actions are defended by Malcolm, both sternly condemned by Macaulay and Malletson.

For three years sole ruler in all but name of Bengal, Clive, in 1760, with a fortune of more than £40,000 a year, returned to England, to be hailed by Pitt as 'a heaven-born general'; in India he was known as *Sabat Jung*, 'the daring in war.' In 1761 he entered parliament as member for Shrewsbury; in 1762 was raised to the Irish peerage as Baron Clive of Plassey; in 1764 was created a Knight of the Bath. But meanwhile in India the Company's affairs, through the dishonesty of its servants, high and low, had fallen into the utmost disorder; and Clive was the only man who could set them right. He arrived at Calcutta in May 1765, and at once applied himself wisely and firmly to reform the civil service and re-establish military discipline. This second governorship, lasting but

twenty-two months, marks the beginning of our Indian administration, as Plassey of our military supremacy.

Early in 1767 Clive quitted India, never to return; in all he had spent there less than a dozen years. This time he came back to England poorer than when he last left it; but this time he came back to encounter a storm of obloquy. The energy with which he had cleansed that Augean stable had raised up a host of influential enemies, who employed their influence to gratify their enmity, to stir up ill-feeling against him. His early proceedings in India were in 1772 made the subject of animadversion in parliament, and next year matter for the inquiry of a select committee. He was examined and cross-examined more like a sheep-stealer than the Baron of Plassey. Indignation at treatment so unmerited found vent at last in the exclamation: 'By heaven, Mr Chairman, at this moment I stand astonished at my own moderation.' The censure implied in the ultimate resolution was hardly wiped out by its rider, that he 'did at the same time render great and meritorious services to his country' (21st May 1773). Sickness, opium, mental depression—on 22d November 1774 Clive died by his own hand. He is buried in the church of Moreton Say, the parish that gave him birth.

Clive's eldest son, Edward (1754-1839), was governor of Madras from 1798 till 1803, and in 1804 was made Earl of Powis, having twenty years earlier married the daughter of the last Earl of Powis of the Herbert line.

See ARCOOT, DUPLEIX, INDIA; Sir John Malcolm's *Life of Clive* (3 vols. 1836), with Macaulay's essay thereon; Colonel G. B. Malleson's *Founders of the Indian Empire: Clive* (1882); and Browning's *Dramatic Idylls* (2d series, 1890). For the conflicting accounts of the manner and place of Clive's death, whether by penknife, razor, pistol, or poison, whether at his mansion in Berkeley Square, or his Shropshire seat, Walcot Park, see Horace Walpole's *Letters to the Countess of Ossory* (i. 155); the *Gentleman's Magazine* for September 1848, p. 227; and several articles in *Notes and Queries* for 1888.

Cloaca, in Zoology, the technical name for the common terminal chamber into which the alimentary canal, the genital and the urinary ducts, all open. A cloacal chamber and aperture occurs in many fishes, in all amphibians, reptiles, and birds, and in the three lowest mammals. In all other mammals the urogenital orifice is independent of the end of the alimentary canal or anus.

Cloaca Maxima, the most important of the sewers of ancient Rome, according to tradition, constructed by Tarquinius Priscus, or by Tarquinius Superbus, to drain off the stagnant waters of the Velabra, a swampy land between the Capitoline and Palatine hills on which the Forum and Circus Maximus also stood. Running from the valley of the Subura, under the Forum along the Velabrum, it opened into the Tiber in an archway still 11 feet wide by 12 feet high, consisting of three concentric arches, built of large blocks of peperino stone, fixed together without cement, of the uniform size of rather more than 5 feet 5 inches long and 3 feet high. The sewer was flushed by a continual stream of superfluous water from the aqueducts. Large portions of this and of the other cloacæ remain entire after two thousand years, but the greater part is buried, by the accumulation of soil, at a considerable depth below the present level of the streets. During the Republic, the surveillance of the Roman cloacæ was one of the duties performed by the censors. The *cloaca maxima* was repaired by Cato and his colleague in the censorship. Agrippa, when ædile, obtained praise for his exertions in cleansing and repairing the cloacæ, and is recorded to have passed through them in a boat. Under the empire, officers called *curatores cloa-*

curum urbis were appointed for their supervision. So thoroughly was the city undermined by these large sewers, that Pliny calls it *urbs pensilis*, a city suspended in the air rather than resting upon the earth.—*Cloacina* ('The Purifier') was a surname of the goddess Venus at Rome.

Clocks. See HOROLOGY.

Clog Almanac, the name given in England to a primitive kind of calendar or almanac, called also a 'rim stock' and 'prime staff.' In Scandinavia it was called a 'Runic staff,' from the Runic characters used in its numerical notation. It was generally of wood (whence its name of 'clog'—i.e. log or block), of about 8 inches in length, but was sometimes of brass, of bone, or of horn. When of wood it was most commonly of box; but elm, fir, and oak were also employed. 'This almanac,' says Dr Plot, in his *Natural History of Staffordshire*, written in 1686, when it was still in use among the common people of that county, 'is usually a square piece of wood, containing three months on each of the four edges. The number of days in them are expressed by notches: the first day by a notch with a patulous stroke turned up from it, and every seventh by a large-sized notch. Some are perfect, containing the dominical letters as well as the prime and marks for the feasts, engraven upon them, and such are our prime staves in the Museum at Oxford: others imperfect, having only the prime and immovable feasts on them, and such are all those I met with in Staffordshire.' The marks on the left side, in the figure, indicate the golden numbers of a cycle showing the new moons throughout the year. On the right side against the 6th January is a star, the symbol of Epiphany; against the 13th St Hilary is shown by the bishop's double cross; 25th, conversion of St Paul, by an axe. The mark against the first notch (or New-year's Day) symbolises the Circumcision of our Lord. Christmas was marked by a horn, the sign of health-drinking—*notans cornua exhaurienda*, as Dr Plot quotes. Examples of the clog almanac may be seen in the British Museum (one cut apparently towards the end of the 17th century); in the Ashmolean Museum and the Bodleian Library at Oxford; in St John's College, Cambridge; and in the Cheetham Library, at Manchester. It is described by the Swedish historian, Olaus Magnus, in the 16th century; and by the Danish antiquary, Olaus Wormius, in the 17th century. Some of the clog almanacs show a peculiar numerical notation. The first four digits are marked by dots; the fifth, by a sign like the Roman numeral V; the next four, by this sign and additional dots; and the tenth, by the sign +. See Chambers's *Book of Days*.

Clog Almanac for January.

Clogher, a decayed episcopal city of County Tyrone, on the Blackwater, 15 miles SSE. of Omagh. The Protestant Episcopal see is now united to that of Armagh. The cathedral and episcopal palace are handsome edifices; but, though formerly a parliamentary borough, the place is now a mere village. Pop. 225.

Clogs are a sort of shoes, the uppers of which are leather and the soles of wood (specially alder

wood). They are much used in the north of England and south-west of Scotland, especially during winter.

Cloister (Fr. *cloître*, *claustrum*, 'an inclosure'), a covered passage or ambulatory running round

Cloister, Killoconel Abbey.

the walls of certain portions of monastic and collegiate buildings. The cloister usually surrounded or ran along three or four sides of a quadrangular area, which was called the *cloister garth*, generally situated on the south or sunny side of the church, as shown under CHURCH in the ground-plan of Durham cathedral. That of Salisbury, one of the finest in the kingdom, is 195 feet square. The roof of the cloister, which was often vaulted, was supported on the side next to the quadrangle by pillars and arches, which were frequently occupied by tracery. The upper portions of these arches above the mullions were often glazed; and sometimes latterly even the whole arches, so that they became a row of windows, as at Gloucester. Cloisters were used for exercise and recreation by the inmates of the religious houses. Occasionally, when wholly glazed, they had cells or stalls for study on the inner side; and very frequently a stone bench may still be seen, which runs along the same side. Many of the larger monasteries had more cloisters than one; and so characteristic were they of the religious houses, that the term cloister came to be used in a general sense for the whole establishment, which is still the sense of the word *kloster* in German. See MONASTERY.

Clonakilty, a seaport of County Cork, at the head of Clonakilty Bay, 33 miles SW. of Cork, with several corn and flax mills, and a considerable trade in grain. There are 'druidical' remains in the neighbourhood. Pop. 3676.

Clones, a town of County Monaghan, 94 miles NW. of Dublin by rail, with spade manufactories, corn-mills, and the remains of an abbey and of a round tower. Pop. 2216.

Clonfert, an ancient episcopal city of Ireland, is in the extreme east of County Galway, and has now a population of 2200. The bishopric was founded in the 6th century, and ceased to be a separate Anglican one in 1602, being ultimately incorporated with Killaloe; but it is still the see of a Roman Catholic bishop. There is another Clonfert, a parish in County Cork.

Clonmel, a municipal borough in Tipperary and Waterford counties, on the Suir, 135 miles SW. of Dublin by rail. It has flour-mills, and a trade in agricultural produce, especially butter. In 1650 Cromwell besieged the town, and demolished the castle. Clonmel gave birth to Sterne and Lady Blessington, and was the chief scene of Smith O'Brien's attempted rising in 1848. Till 1885 it sent a member to parliament. Here Bianconi (q.v.)

first established his jaunting-cars; and Clonmel is still a great tourist centre. Pop. 2157.

Clontarf, a town in County Dublin, 3 miles ENE. of Dublin city. It is much frequented for sea-bathing. Here, in 1014, Brian Boru won a great victory over the Danes. Pop. (1881) 4210.

Clootz, JEAN BAPTISTE DU VAL DE GRÂCE, BARON, better known as Anacharsis Clootz, was perhaps the most singular of all the frothy enthusiasts brought to the surface of society by the French Revolution. He was born near Cleves in 1755, and from his eleventh year was educated in Paris. While still young he traversed Europe under the name of Anacharsis, lavishing his money to promote the union of all nations in one family. In the French Revolution he saw the fulfilment of his dreams. He constituted himself the 'orator of the human race,' and wearied out the National Assembly with his endless rant, at one time leading in a tatterdemalion regiment of strangers dressed in the costumes of different nations, at another raving at Christianity and preaching the worship of Reason. He gave his vote for the king's death 'in the name of the human race.' With all its folly his enthusiasm was honest, and he was at once hated and feared by the jealous Robespierre, who had him excluded as a noble from the Jacobin Club, and at last involved him in St Just's impeachment of Hébert and his adherents. He was guillotined, March 23, 1794, preaching materialism to the last, and protesting against his sentence, as usual, 'in the name of the human race.' Of his absurd books, may be named: *Certitude des Preuves du Mohammedisme* (Lond. 1780), *L'Orateur du Genre Humain* (1791), and *Base Constitutionnelle de la République du Genre Humain* (1793). See his Life by Avenel (2 vols. Paris, 1863).

Close is an inclosed place, and specially in England, the precincts of a cathedral. In Scotland, however, the word means a narrow side-street, or a passage leading from the street to a court, or to the stair of a block of tenements.

Close Time, the time during which game, certain wild birds, salmon, and some other fish, may not be shot or caught, varies for the different animals and for different places. Lists of the dates may be found in such almanacs as Whitaker's.

Closet, in Heraldry, the half of the Bar (q.v.).

Closure (formerly in the French form *clôture*), the name used for a power given in 1882 to the Speaker of the House of Commons, or chairman of committees, to close a debate when it seems to him that the subject has been discussed, and he is authorised to do so by a motion duly supported. For the rules of procedure, see PARLIAMENT.

Clotaire I. (*Illthar*), son and successor of Clovis (q.v.), first king of the Franks in Gaul, reigned as sole king from 558 to 561.—CLOTAIRE II., a king of the same Merovingian dynasty, reigned over the Franks thirty years later. See FRANCE.

Cloth. See WOOLLEN MANUFACTURE.

Clothes-moth. See MOTH.

Clotho, one of the Fates (q.v.).

Clotho, a genus of spiders which spins a curious tent for itself and its young. See SPIDER.

Clotilda, ST, born in 475, was the daughter of Chilperic, king of Burgundy, and in 493 became wife of Clovis, king of the Franks. She was the chief means of securing the conversion of her husband to Christianity, and largely influenced his life. After his death she lived a life of austerity at Tours, where she died in 545. She was canonised a few years after. Her remains were buried in the church of St Geneviève at Paris, and burnt

at the Revolution to prevent their desecration; the ashes are still in the church of St. Leu.

Cloudberry (*Rubus Chamaemorus*), a plant related to the bramble, although of very different appearance, having a herbaceous single-flowered stem destitute of prickles. The plant is of humble growth, 8 to 10 inches in height; the leaves few, large, lobed, and kidney-shaped; the flower large and white; the fruit orange red, equal in size to a bramble-berry, and of an agreeable flavour. It is a native of the northern parts of Europe, Asia, and America. In Britain it is chiefly confined to elevated moors; in Norway and Sweden it is much more abundant, and the fruit is highly valued and made into excellent preserves.

Clouds are masses of fog, consisting of minute particles of water, often in a frozen state, floating in the atmosphere. When air has its temperature lowered below the saturation point, either by ascending and becoming rarer, or by meeting a colder current, a portion of the vapour loses its gaseous form, and becomes condensed into minute specks of water. It has been shown by Dr Aitken that this condensation always takes place round a small particle of dust. A cloud, therefore, does not consist of vapour, in the proper sense of the word, but of very small drops of water. How this water-dust is suspended in the atmosphere—why the particles do not descend as soon as formed, has never been thoroughly explained. Professor G. G. Stokes holds that the rate of fall is rendered exceedingly slow by the friction and drag of the air-particles, just as fine powders remain suspended for a long time in liquids of much less specific gravity than themselves. Besides, as Sir J. Herschel says, ascending air-currents also oppose the fall of clouds, for the air may be ascending faster than the particles of the cloud are falling through it; while at night, in the absence of rising currents, clouds often descend to, and dissolve in lower and warmer levels. The conditions under which clouds are formed, and afterwards deposited in rain, are more fully considered under EVAPORATION, DEW, RAIN, SNOW-LINE. The present article is confined to a description of the various kinds of clouds and of the weather they indicate.

A general haze of precipitated vapour covering the sky, and coming down to the earth, is termed a *Fog* or *Mist*; and the term cloud is usually confined to masses of fog floating in the higher regions, and not descending to the ground. They are mostly within a mile of the earth's surface; and few are more than six miles above it. From observations made at Upsala in Sweden, it has been found that there are three principal cloud layers: the low clouds at from 2000 to 6000 feet; middle clouds, 12,000 to 15,000 feet; and high clouds, 20,000 to 27,000 feet. These three layers are found at apparently much the same heights all over the earth. Clouds spread and move with the wind in varied, often grand forms; they are generally disposed in beds parallel to the earth's surface; vertical clouds occur rarely, if at all.

Mr Luke Howard's classification of clouds, proposed in 1802, into three primary forms—Cirrus (Cir.), Cumulus (Cum.), and Stratus (Str.); three intermediate—Cirro-cumulus (Cir.-c.), Cirro-stratus (Cir.-s.), and Cumulo-stratus (Cum.-s.); and one compound form, Nimbus (Nim.)—has been universally adopted, and has been shown by the Hon. Ralph Abercromby and others to hold good in all climates and atmospheric conditions.

Cirrus, or curl cloud, consists of parallel, curling, flexuous, diverging, and partly straight fibres, increasing in any or in all directions by elongation, branching, or addition of new fibres. It is the

highest and least dense of clouds; varies most in extent, direction, and shape; retains longest its varied outlines; and is the longest illuminated after sunset and before sunrise. It has been compared to a mare's or cat's tail, a lock of hair, fine

Cirrus.

trellis-work, or thin silvery streaks, and it may cover all the sky. Threads and groups of Cir., during gentle wind after severe weather, presage serene settled weather. But after a long tract of fair days, whitish filaments or parallel bands of Cir. crossing the sky, with the ends converging by perspective in each horizon, foretell a change to wet; they move with the upper currents of the atmosphere, and generally indicate by this motion a change of wind long before it is felt on the earth's surface. Cir., being so high, consists of minute ice crystals, whose refractions and reflections produce the halos, coronæ, and mock suns and moons almost restricted to this cloud and its derivatives the Cir.-s. and Cir.-c. Cir., especially with fine tails, varying much in a few hours, presages rain or snow, and windy variable weather.

Cumulus, ball of cotton, day or summer cloud, consists of dense, convex, hemispherical, or conical heaps of small roundish clouds, piled or stacked on each other. The heaps enlarge upwards from a

Cumulus.

horizontal base, and have rounded or rocky tops; they sometimes unite into stupendous white-topped mountains. It is formed by the condensation of vapour in local ascending columns of air, and is generally at from 4000 to 6000 feet elevation. Cumuli often begin after sunrise as a few scattered specks in the clear sky; these specks enlarge and unite to form clouds, which nearly cover the sky in the afternoon, and generally decrease and vanish about sunset; but rain follows if they increase in number and darkness in the evening. Cum., of

pleasing forms, dispositions, and colours, and of moderate size, presages fine dry warm and calm days; but cold, rain, and tempest follow dark, abrupt, dense, shaggy Cum., covering the sky, and rolling on each other. Hemispherical, silvery white Cum. presages thunder.

Stratus, fall or night-cloud, the lowest of clouds, is a widely extended, horizontal sheet, of varied thickness, seldom rising above 4000 feet, and often quite close to the earth's surface. It is common in

Stratus.

summer and autumn, often from sunset to sunrise, and is densest at or after midnight. It arises in calm clear evenings, after warm days, from the sinking and flattening out of Cum., from the cooling of moist air on damp ground, marshes, lakes, rivers, or from the cooling of moist air mixed with smoke enveloping great cities. From a height it is seen spreading around like a sea, and creeping up hillsides. After sunrise it rises higher, sometimes forming Cum., and sometimes entirely disappearing; but it may quietly accumulate in layers, and become Nim.

Cirro-cumulus, or sonder-cloud, consists of Cir. compressed into dense roundish-white cloudlets, or woolly irregular tufts, and is found either in the middle or high cloud layers. It forms the well-known mackerel sky, but is also often seen through breaks in lower clouds moving differently. It may vanish or pass into Cir. or Cir.-s. Solar and lunar coronæ appear in it. It occurs in warm dry weather and between summer showers, and presages increased heat. Cir.-c. very dense, round, and close, and with Cum.-s., presages a storm or thunder. In winter it precedes a thaw and warm wet weather.

Cirro-stratus, or vane-cloud, consists of long, thin, horizontal clouds, sometimes hairy, with bent or undulated edges. It is found on the advancing side of cyclonic storms, and hence is a sure prognostic of wind or rain. Being of great extent, but little depth, and at a great height, it is the most usual source of solar and lunar halos.

Cumulo-stratus, or twain-cloud, is a Cir.-s. mixed with Cum. heaps, or a wide flat base surmounted by a bulky Cum., with fleecy protuberances or rocky and mountain masses. It is much denser than Cum., though being formed by less rapidly ascending currents, the air is not dry enough to round off sharply its tops. It often forms vast banks of cloud, with overhanging masses. It is common towards night in dry windy weather, when it has a leaden hue. It generally arises from Cum. becoming denser, wider, and protruding in large irregular projections over the base. It tends to overspread the sky, and partly or wholly to become Nim., and fall in showers. Cum.-s. is intermediate

between clouds indicating fair and those indicating rough, rainy weather, and attends sudden atmospheric changes. Distinct Cum.-s. forms before thunder. Cum.-s. increases the grandeur of mountain scenery, and drops on and envelops mountaintops like a curtain.

Nimbus, or Cumulo-cirro-stratus, the black rain-cloud, is a cloud, or mixed system of clouds, with rain or snow falling from it. It is a dense, continuous, horizontal black or gray sheet, with fringed edges, having rolling masses of Cum. above it and topped by Cir. Before rain, vast towering masses of Cum. often pass into Cum.-s., which, increasing in density, darkness, irregularity, and extent, become Nim. capped by Cir.-s. Thunderstorms are always accompanied by Nim. in its most perfect form.

The term *scud* has been applied to loose vapoury fragments of clouds driven by wind, and *cumulonus* to very shaggy cumuli.

The formation and height of clouds depend on the quantity of vapour in the air, the course and height of air-currents, the climate, season, temperature, disposition, and extent of sea and land, and the height of land. The highest clouds yet observed were Cir. at 43,800 feet elevation. Remarkable cloud-rings prevail over the calm zones of the equator, and over those of Cancer and Capricorn. The tops of mountains are often capped by clouds formed by the moisture in the air condensing as it is forced up and over the hill. Clouds, viewed from above in bright sunshine by the astronaut or mountaineer, appear as dense volumes of steam or masses of white cotton.

Clouds moderate the sun's rays during day, and the earth's radiation during night. They always exhibit positive or negative electricity, but of greatest tension in thunderstorms. They are the carriers of the moisture required by plants; of the water of springs, lakes, and rivers; and of the polar, glacial, and winter snows, which cover temporarily or permanently parts of the earth.

In Britain, six or seven tenths of the sky is on an average daily obscured by clouds. There is most cloud in winter, and about mid-day, and least in May or June, and during night. Summer and autumn nights are freest of clouds. All the forms of clouds may be seen in one day, often very much commingled.

Clough, ARTHUR HUGH, poet, was born at Liverpool, January 1, 1819. His father, a cotton-merchant there, belonged to an old Denbighshire family. In the winter of 1822-23 he emigrated to Charleston, in South Carolina, and there the boy mostly lived in the midst of a home-life of singular happiness, until in November 1828 he was sent back to school at Chester, and to Rugby in the summer following. Dr Arnold had already been head-master for a year, and his high ideal of Christian duty early made a profound impression upon the boy. At Rugby he was foremost in athletic sports, edited for some time the school magazine, and not only worked his way to every honour open to him, but gained the warm affection of all his school-fellows. In November 1837 he entered Balliol College, Oxford, but astonished all who knew his powers by only obtaining a second-class in 1841. In the spring of the following year he was elected to a fellowship at Oriel. Clough's residence at Oxford had fallen at a time of fierce theological controversy, and his sensitive spiritual nature reflected all the unrest of the atmosphere around him. For a time he fell under the spell of Newman's influence, but this was soon followed by a period of severe inward struggle between his absolute honesty of mind and the religious prepossessions of his youth, the result of which was that he felt it his duty to withdraw in

1848 from Oriol. A little earlier he had published his first long poem, the *Bothie of Tober-na-Vuolich*, a 'Long Vacation pastoral' in hexameter verse. He next spent some time in travelling in France and Italy, part of the time with Emerson, and was appointed on his return (October 1849) Warden of University Hall, London. His life here was far from congenial to him, but he found much help in the warm friendship of Carlyle. At Rome, in 1849, he had written his *Amours de Voyage*, and at Venice, during a holiday in 1850, he wrote *Dipsychus*. In 1852 he resigned his office, and sailed to America; but an examiner-ship in the Education Office soon recalled him to England. In June 1854 he married, and the remaining seven years of his life were spent in the calm peace of domestic happiness, free at once from the unrest of religious perplexity and the vexation of his earlier monetary liabilities undertaken for the sake of his father's business. In the spring of 1856 he was nominated secretary to the Commission for examining scientific military schools on the Continent, and the duties of this office carried him to France and to Vienna. But his health now began to give way, and he was advised by his physicians to travel. After visits to Greece, Constantinople, the Pyrenees, and Italy, he was carried off at Florence by paralysis succeeding a malarial fever, November 13, 1861.

Clough's poetry reflects with absolute sincerity all the spiritual unrest and conflict of his life, his passionate love of truth, and intense longing for reality. His few short lyrics are almost perfect in form and matter, but, as an artist in words, his best gift was perhaps his undeniable humour, which is of a rare and indeed exceptional quality. But his true significance is that pointed out with sure insight by Mr Lowell: 'We have a foreboding that Clough, imperfect as he was in many respects, and dying before he had subdued his sensitive temperament to the sterner requirements of his art, will be thought a hundred years hence to have been the truest expression in verse of the moral and intellectual tendencies, the doubt and struggle towards settled convictions, of the period in which he lived.'

Clough is the subject of Matthew Arnold's elegy *Thyrsis*, one of the finest tributes of passionate admiration to the dead in the English language, almost worthy indeed to be compared with the *Lycidas* of Milton, the *Adonais* of Shelley, and the *In Memoriam* of Tennyson. No truer words have been spoken of Clough than these:

The music of his rustic flute
Kept not for long its happy country tone;
Lost it too soon, and learnt a stormy note
Of men contention-tost, of men who groan,
Which tasked his pipe too sore, and tired his throat.

See Samuel Waddington's Monograph (1883). A collected edition of Clough's *Poems* was published in 1862, with a memoir by F. T. Palgrave, and his *Poems and Prose Remains*, edited by his wife, with an admirable short memoir, in 2 vols. in 1869.

Clove Bark, a name vaguely used for various aromatic drugs; some belonging to the clove, others to the cinnamon alliance. To the former class belong the bark of *Eugenia caryophyllata* of Ceylon, &c.; to the latter, the *Culilawan* bark (*Cinnamomum Culilawan*) of the Moluccas.

Clovelly, a coast village of North Devon, 11 miles WSW. of Bideford. From its rude little pier it climbs 400 feet upwards in a steep narrow combe, white house rising over white house, and all nestling in flowers and greenery. Dickens describes it in *A Message from the Sea*. Pop. of parish, 787.

Clover, or TREFOIL (*Trifolium*), a genus of Leguminosae, sub-order Papilionaceae, containing a great number of species, natives chiefly of temperate

climates, abounding most of all in Europe, and some of them very important in agriculture as affording pasturage and fodder for cattle. The name clover is indeed popularly extended to many plants not included in this genus, but belonging to the same natural order, and agreeing with it in having the leaves formed of three leaflets, particularly to those of them which are cultivated for the same purposes, and sometimes collectively receive from farmers the very incorrect designation of *artificial grasses*, in contradistinction to *natural grasses*—i.e. true grasses. See MEDICK and MELILOT. The true clovers (*Trifolium*) have herbaceous, not twining stems; roundish heads or oblong spikes of small flowers; the corolla remaining in a withered state till the ripening of the seed; the pod inclosed in the calyx; and containing one or two, rarely three or four seeds. About 20 species belong to the flora of Britain, and many are North American.—The most important of all to the farmer is the Common Red Clover (*T. pratense*), a native of Britain and of most parts of Europe, naturalised in America, and growing in meadows and pastures. It is a perennial, but is generally treated as if it were a biennial. This plant was formerly reputed very noisome to witches; knights and peasants wore the leaf as a potent charm against their arts. The Zigzag Clover (*T. medium*), also called Meadow Clover, Marl-grass, and Cow-grass, much resembles the Common Red Clover, but is easily distinguished by the stems being remarkably zigzag, and more rigid than in *T. pratense*; the heads of flowers are larger, more lax, more nearly globose, and of a deeper purple colour; and the leaflets have no white spot. It is a common plant in Britain and most parts of Europe, and grows sparingly in the

A, White Clover (*Trifolium repens*).
B, Red Clover (*Trifolium pratense*).

United States.—White or Dutch Clover (*T. repens*) is also a common native of Britain and of most parts of Europe, and grows everywhere in North America. When a barren heath is turned up with the spade or plough, White Clover almost always appears. This is sometimes but erroneously called the Shamrock (q.v.). The flowers of all kinds of clover are the delight of bees, but those of this species perhaps particularly so.—Alsike Clover (*T. hybridum*), a perennial species introduced from the south of Sweden about 1850,

has proved a most valuable forage plant.—Crimson Clover, or Italian Clover (*T. incarnatum*), an annual, native of the south of Europe, with oblong or cylindrical spikes of rich crimson flowers, is much cultivated in France and Italy, and has of late been pretty extensively grown in some parts of England, producing a heavy crop. The Crimson Clover is also sometimes employed as a decorative annual in the flower-garden.—Moliner's Clover (*T. Molineri*) very much resembles Crimson Clover, but is biennial, and has pale flowers. It is cultivated in France and Switzerland.—Alexandrian Clover, or Egyptian Clover (*T. Alexandrinum*), an annual species, a native of Egypt, universally cultivated in its native country, where it is the principal fodder for cattle, has been tried in Britain, but the colder climate has been found to render it less luxuriant and productive. It is supposed to be one of the best kinds of clover for many of the British colonies. It has oval heads of pale-yellow or whitish flowers.—Yellow Clover, or Hop Trefoil (*T. agrarium*), is very common in dry gravelly soils in Britain, and in parts of the United States, but is not much esteemed. It has smaller leaves and heads of flowers than any of the cultivated species. Its flowers are yellow.—The Showy Clover (*T. speciosum*) is the only plant made into hay in the island of Zante, and has therefore been recommended on trial as a fodder plant in the south of England and the warmer colonies. None of the strictly native North American species have been much utilised as forage plants.

It is little more than a century and a half since clovers were introduced into field-culture in Britain. They are now universally cultivated on large farms in alternation with grain-crops. The kinds most generally sown are the Common Red, Cow-grass, Dutch White, Yellow, and Alsike. The Common Red is the finest and most valuable, but it is difficult to grow unless on naturally rich soils. Land must be thoroughly cleaned of perennial weeds before it is sown with clover, as the land cannot be subjected to cultivation while it is under this plant; clover, therefore, is always sown in the end of the rotation, or as near the fallow or turnip crop as possible. A well-manured soil greatly assists in keeping the plants from dying out in spring. Clovers, like grasses, play a most important part in restoring fertility to land which has been exhausted by grain-crops. Their leaves gather food—carbonic acid and ammonia—from the atmosphere, which they store up in their roots and stems; and these, on decomposing, afford food for cereals or other crops which are more dependent on a supply within the soil.

The caterpillars of a number of species of moth feed on the leaves of different kinds of clover; but the insects most injurious to clover crops are weevils of the genera *Apion* and *Sitona*. See CLOVER-WEEVIL, and WEEVIL.

Clover-weevil, a small black beetle of the genus *Apion*, which in larval and adult state infests clover and other leguminous plants. See WEEVIL.

Cloves (Span. *clavo*, 'a nail') are the flower-buds of the Clove-tree (*Caryophyllus aromaticus*). The genus to which this tree belongs is of the natural order Myrtaceæ; the tree is from 15 to 40 feet high, with a beautiful pyramidal head. The leaves are large, ovate-oblong, acuminate at each end, evergreen; the flowers are small, but produced in great profusion in cymes. Leaves, flowers, and bark have an aromatic odour. The ripe fruit resembles an olive in shape, but is not quite so large; it is of a dark-red colour; it sometimes appears in commerce in a dried state, under the curious name of *Mother Cloves*; it has an odour and flavour similar to cloves, but much weaker;

the broken fruit-stalks are sometimes also used for the same purposes as cloves; but the flower-buds themselves are the principal product of the tree. They are gathered, and are dried by exposure to the smoke of wood fires, and afterwards to the rays of the sun, or by the latter alone. When first gathered they are reddish, but become of a deep-brown colour. The unexpanded corolla forms a little round head at the end of the calyx tube,

Clove:

a, a branch with leaves, buds, and flowers; b, a bud.

which is about half an inch long, and thus the appearance is not unlike that of a little nail, whence the name. The clove-tree is a native of the Moluccas, and the Amboyna cloves are still esteemed the best; but the tree is now cultivated in Java, Sumatra, Réunion, Mauritius, Zanzibar, Guiana, and some parts of the West Indies. The Dutch, in order to secure a monopoly and keep up the price, destroyed the trees in the other Molucca Islands in the 17th century, and confined the cultivation of them to Amboyna. In 1770 the French succeeded in introducing the plant into the Isle de Bourbon (Réunion). It is not deemed quite certain that cloves are the *karyophyllon* of the ancient Greeks; but before the discovery of the Spice Islands eastern merchants brought them from Arabia, Persia, and Egypt, to the harbours of the Mediterranean, from which the Venetians and Genoese diffused them over Europe.

The Wild Clove-tree of the West Indies is *Myrcia acris*. See MYRCIA.

The properties of cloves depend chiefly on an essential oil, *Oil of Cloves*, which forms one-fifth or one-sixth of their whole weight. They are used for flavouring dessert dishes and articles of confectionery, also for driving moths from clothing, furs, &c., by placing them in the boxes or drawers with the clothing. They are also reputed to possess febrifuge properties. They have a hot taste and a characteristic odour. The oil of cloves is obtained by repeatedly distilling cloves with water, when two oils pass over, one of which is lighter and the other is heavier than water. The oil has a hot acrid taste, is of a light yellow when pure, and brown red when not so carefully prepared. It has a well-known odour, and is soluble in ether, alcohol, and the fixed oils. It is useful in medicine to check nausea and griping, caused by the administration of purgatives, and has consider-

able reputation as a cure for toothache. It is also employed in the scenting of soap, and by the distiller. *Tincture of Cloves* is obtained by treating cloves with alcohol for several days, and then straining, or by a solution of the oil of cloves in spirits of wine. It is added, in medicine, to stomachic, tonic, and purgative mixtures. Cloves are adulterated by adding to the fresh spice more or less of the buds from which the oil has been distilled, and which are thereby rendered practically worthless. The exhausted buds are made to appear fresh by rubbing them between the hands moistened with sweet oil, or otherwise varnishing them with a thin coating of oil.

Clovis (old Ger. *Chlochoig*, modern Ger. *Ludwig*, Fr. *Louis*), king of the Franks, was of the Merovingian race, and was born 465 A.D. By the death of his father, Childeric (481), he became king of the Salian Franks, whose capital was Tournai. His first achievement was the overthrow of the Gallo-Romans under Syagrius, near Soissons. He then took possession of the whole country between the Somme and the Loire, and established himself in Soissons. In 493 he married Clotilda, daughter of a Burgundian prince. His wife was a Christian, and earnestly desired the conversion of her husband. In a great battle with the Alemanni near Cologne, Clovis was hard pressed, and as a last resource invoked the god of Clotilda, offering to become a Christian on condition of obtaining the victory. The Alemanni were routed, and on Christmas Day of the same year Clovis and several thousands of his soldiers were baptised by Remigius, Bishop of Rheims. Most of the Western Christian princes were Arians, but Clovis was strictly orthodox, and, in consequence, was saluted by Pope Anastasius as the 'Most Christian King.' In 507, love of conquest concurring with zeal for the orthodox faith, Clovis marched to the south-west of Gaul against the heretic Visigoth, Alaric II., whom he defeated and slew at Vouglé, near Poitiers, taking possession of the whole country as far as Bordeaux and Toulouse; but he was checked at Arles in 507, by Theodoric, king of the Ostrogoths. Clovis now took up his residence in Paris, where he died in 511. His great aim was the subjugation of all the Frankish princes, and the union of the whole Frankish people into a single powerful kingdom. — Clovis II., son of Dagobert, reigned over the Franks from 638 to 656.

Clowes, WILLIAM, an Elizabethan surgeon of distinction, was born about 1540, became surgeon at St Bartholomew's Hospital, served with Leicester in the Low Countries, and also on board the fleet that defeated the Spanish Armada. He became surgeon to the queen, and after a prosperous practice in London retired to a country house in Essex, where he died in 1604. He wrote five books in clear and vigorous English, of which two long continued popular: *A Prooved Practise for all Young Chirurgians* (1591), and *A Treatise on the Struma* (1602).

Clown. See JESTER, PANTOMIME.

Cloyne, an ancient episcopal town of County Cork, 15 miles ESE. of Cork. The cathedral was founded in the 8th century by St Colman: opposite is a finely preserved round tower over 90 feet high. About 1430 the see was united to that of Cork, separated in 1678, and reunited in 1835; the town still gives its name to a Roman Catholic diocese. Berkeley was Bishop of Cloyne (1734-53). Pop. 1126.

Clubbing, in cabbages, turnips, and other plants of the genus *Brassica*, a diseased growth of tubercular excrescences in the upper part of the root or lower part of the stem, caused by the larvæ of the Cabbage-fly (q.v.) and of other insects, by

which the vigorous growth of the plant is prevented, and crops are often much injured. It is common for gardeners to cut away these excrescences, with their contained larvæ, in planting out young cabbages, &c.; and where they are not so numerous that the injury done by the knife is necessarily great, this plan succeeds very well. Dressings of gas-lime applied to the soil some time before planting is the best preventive of this evil; but change of crop, when practicable, is of all things the most commendable. Clubbing is sometimes confounded with Anbury (q.v.), from which it is quite distinct.

Club-foot (Lat. *talipes*) is a distortion of the foot primarily due to shortening occurring in one or other of the groups of muscles which carry out its intricate movements; subsequently, this error in the muscular activity becomes aggravated by shortening of the ligaments which bind the bones together, and ultimately the shape of the bones themselves becomes altered so as to constitute a very serious deformity, difficult to correct. In the majority of cases the condition is congenital, and at the time of birth it is usually only the muscular structures that are affected. Thus it is of great importance to recognise its presence early in life; for until the ligaments and bones become altered, it may be remedied by very simple means, such as manipulation and electric stimulation of the affected groups of muscles. If these simple measures appear ineffectual, recourse must be had to the division of the tendons (Tenotomy, q.v.), by which the shortened muscles are attached to the bones of the foot. The foot thus freed from the cause of the distortion, should be placed at rest in good position within an immovable apparatus, such as a plaster of Paris case, until healing of the tendons has occurred. The weakened parts should then be

Club-feet:

A, *Talipes equinus*; B, *Talipes varus*.

exercised by suitable manipulations which restore their strength. In very bad cases it may be necessary to remove portions of the distorted bones and thus restore the natural shape of the foot.

These affections are very markedly hereditary, and they are in all probability due to disordered function in the nerves leading to the affected muscles, or in the brain or spinal cord, in which these nerves have their origin. Four chief varieties of club-foot are recognised by surgeons: (1) *Talipes equinus* (fig. A), in which the heel is drawn up, and the patient walks on the under surfaces of the toes; (2) *Talipes calcaneus*, in which the reverse condition is present, and the patient walks on the heel only; (3) *Talipes varus* (fig. B), in which the patient walks on the outer border of the foot; and (4) *Talipes valgus*, where the inner edge of the sole alone touches the ground. See DEFORMITIES.

Club-moss. See LYCOPODIACEÆ.

Club-rush. See SCIRPUS.

Clubs. The word *club* is from the same root as *clump*; and its secondary meaning of 'a collection of persons' is illustrated by 'a clump of trees.' As specially applied to a select association meeting for social intercourse, it dates from the 17th century, and the use has since been extended to other bodies having a common object, such as literature, science, amusements, politics, or the furtherance of material interests. The practice of some kind of club-life is almost universal; and can be traced in the earliest civilisations. Modern travellers in Africa, the Pacific, and elsewhere, constantly speak of a kind of club-houses where the men meet for gossip and recreation. Vacancies in the public tables among the Spartans were filled up by ballot, and Aristotle refers to members of the same locality in Greece as clubbing for merry-making. Many such associations both in Greece and Rome were, however, really secret societies for the cultivation of religious mysteries; others were more of the nature of Guilds (q.v.). But there are records of social clubs more closely allied to the modern form, and Cicero tells of his pleasure in frequenting such gatherings. We also hear of a club of old soldiers belonging to the armies of Augustus, and another among the officers of an African legion. Women had their sociable *collegia*.

In England the history of clubs dates from the Court de Bone Compaignie mentioned by Occleve in the early part of the 15th century. Nearly two hundred years later the symposia originated by Raleigh made the Mermaid Tavern in Bread Street famous, while Ben Jonson is said to have founded a similar gathering at the Devil Tavern. The Apollo is connected with Jonson's *Leges Convivales*. The Rota (1659) and the clubs of the Restoration were mainly political. The members of the Calves' Head Club (q.v.) were supposed to ridicule the memory of Charles I. The portraits of the members of the Kit Kat Club (1700) are still preserved. Addison, Steele, and the essayists of the *Spectator* and *Tatler* class have made us familiar with the coffee-house and tavern clubs of their time. The Royal Society Club (1743) is the earliest of the many dining-clubs associated with the learned societies. To Reynolds is due the institution of the still existing Literary Club (1762), which numbered so many distinguished members, among them Dr Johnson, who established the Ivy Lane and other clubs of a less formal character. Good fellowship and conversation were the leading features of these societies.

The present type of English club is quite different from the earlier bodies bearing the same name. It arose about the commencement of the 19th century, and is characterised by dining and other arrangements whereby members seek to preserve their independence while sharing in the benefits to which their united subscriptions contribute. The modern club-house is generally a spacious and handsome building, with dining, smoking, billiard, newspaper, writing, and drawing rooms, &c. Some possess libraries, the most extensive being that of the Athenæum, which owns one of the choicest collections of books of reference in London. The Garrick is famous for its theatrical pictures. Portraits of eminent members are to be found on the walls of many club-houses. Clubs are usually managed by a changing committee who submit their accounts and report to an annual meeting. Some are proprietary. The number of members is generally limited. They are either elected by a ballot of the whole club, a certain number of black-balls or contrary votes excluding, or by the committee, who sometimes choose all or a select number. The revenue is derived from the sale of provisions, &c. consumed in the house, and from an entrance fee and annual subscription paid by each

member. Some clubs have a dining-room to which strangers may be invited; in others a select number of honorary members are admitted. House-dinners are a revival of a former habit. Many of the recent clubs contain bedrooms for members. Concerts and entertainments are also innovations. Moderate card-playing is allowed, but games of chance are invariably forbidden in respectable English clubs. Clubs have been instituted to unite persons of every class, profession, and opinion. There are clubs for ladies alone, and some to which ladies are admitted on equal terms with gentlemen. In others ladies are allowed as guests. It is difficult to say where the club proper ends and the mere drinking saloon commences; some of the numerous working-men's clubs and inferior political clubs fall in the latter class. Others are developments of the old betting and gambling rooms.

The best organised and finest clubs in the world are in London, where there are over a hundred of a high class. The chief among them are the Albemarle (1875), for ladies and gentlemen; Army and Navy (1838); Arthur's (1765), social; Arts (1863); Athenæum (1824), literature, science, and art; Bachelors' (1881), ladies admitted; Boodle's (1762), social; Brooks's (1764), Liberal politicians; Burlington Fine Arts (1866), exhibitions held; Carlton (1832), for Conservatives; City Conservative (1883); City Liberal (1874); Conservative (1840); Constitutional (1883), for Conservatives; Cosmopolitan, conversation; Devonshire (1875), for Liberals; East India United Service (1849); Garrick (1831); German Athenæum (1869), entertainments given; Grillion's (1812), breakfast parties; Grosvenor (1883), social; Guards' (1813); Hogarth (1870), artistic; Isthmian (1882); Junior Army and Navy (1869); Junior Athenæum (1864); Junior Carlton (1864); Junior United Service (1827); Literary (1762); Lyric, entertainments given; National (1845), Church of England; National Liberal (1882); National Union (1887), for Unionists; New Athenæum (1878); New University (1863); Oriental (1824); Orleans (1877); Oxford and Cambridge (1830); Press (1882); Reform (1836), for Liberals; St George's (1874), social; St Stephen's (1870), for Conservatives; Salisbury (1880), ladies admitted; Savage (1857), literature, drama, &c.; Saville (1868); Scottish (1879); Thatched House (1865); Travellers' (1819); Turf (1868); Union (1822); United Service (1815); White's (1730); Windham (1828). County clubs are to be found in all English provincial towns. At Edinburgh the New Club (1787), and in Dublin the Kildare Street (1790), are equal to the best metropolitan clubs. The English in India and the colonies possess luxurious club-houses in which bedrooms for temporary visitors are a convenience.

Well-appointed clubs in the English style have been established in all the leading cities of the United States. Among the best in New York are the Lotos (1870), Union League (1863), Century, Manhattan, Union, Knickerbocker, and University. Gambling and the giving of dramatic and musical entertainments and exhibitions of pictures are special features of club-life on the European continent. The Jockey Club (1833) and the Union Artistique 'Cercle des Mirlitons' (1863) at Paris are representative examples. The political associations formed in Paris at the time of the first revolution exercised considerable influence on public affairs. In 1848 similar bodies in Germany and Austria were suppressed by order of the police. 'Club' is frequently used as an equivalent to society, as in benefit societies, Alpine Club (q.v.), Book-club (q.v.), and cricket, cycling, yachting, boating, and racing clubs. The word has been adopted in most European languages, although Cercle in France and Circolo in Italy are used.

See Ned Ward, *The Secret History of Clubs of all Descriptions* (1709); Ward, *Account of all the most Remarkable Clubs and Societies in London and Westminster* (1750); C. Marsh, *The Clubs of London, with Anecdotes of their Members* (2 vols. 1832); *The London Clubs* (1853); Admiral W. H. Smyth, *Sketch of the Royal Society Club* (4to, 1860); J. Timbs, *Club-life in London* (2 vols. 1866); J. Strang, *Glasgow and its Clubs* (1857); W. Arnold, *The Sublime Society of Beefsteaks* (1871); Col. G. J. Ivey, *Clubs of the World* (1880); Sir P. G. Egerton, *Grillon's Club* (privately printed, 1880); *Club-Almanach* (Paris, 1883-84, discontinued); L. Fagan, *The Reform Club* (4to, 1887); F. G. Waugh, *Members of the Athenæum Club* (1824-87; privately printed, 1888). The rights and obligations of members are discussed by A. F. Leach, *Club Cases* (1879), and J. Wertheimer, *Law relating to Clubs* (1885).

Clugny, or **CLUNI**, an industrial town in the French department of Saône-et-Loire, on the Grosne, 15 miles NW. of Mâcon by rail. Pop. 3653. The famous Benedictine abbey, founded here in 910 by the Duke of Aquitaine, had two centuries later attained a degree of splendour and influence unrivalled by any similar institution of the middle ages; at its height, Clugny stood second to Rome alone as a chief centre of the Christian world. It was the asylum of kings, the training-school of popes; its abbot took rank above all others, issued his own coinage, and was a power in the political world; it was enormously wealthy, and covered Europe with its affiliated foundations. Two hundred priors of subordinate houses assembled here in the 12th century, and in the 15th century there were said to be over 2000 religious houses that were offshoots of or connected with the abbey in France, Italy, Spain, England, Germany, and Poland; although the alphabetical list of Clugniac foundations in the 15th century, at the end of the *Bibliotheca Cluniacensis*, represents only 825. In England the extension of the order dates from the Conquest; William and his successors were devoted to Clugny, and numerous foundations were shortly established, of which the priory of Lewes (1077) became the chief. At their ultimate suppression in 1539 these numbered 35, exclusive of such Scottish foundations as Paisley and Crossraguel. In the 16th century, the conventual buildings at Clugny covered upwards of 25 acres. The grand basilica or abbey church, commenced by St Hugh, the eighth abbot, in 1089, and dedicated by Pope Innocent II. in 1131, was, until the construction of St Peter's at Rome, the largest church in Christendom. Of this magnificent and imposing pile one tower and part of the transept alone remain; the site of the nave is traversed by a road. The abbey, over which cardinal-ministers and princes of the blood had once ruled as commendator-abbots (see COMMENDAM), had outlived both its utility and its importance; it was no longer a great seat of learning, and its 300 monks had dwindled to 40, when in 1790 the order to whom Pope Urban II. had said, 'Ye are the light of the world,' was finally suppressed. Its library was the richest and most important in France, and its archives are of the greatest value to monastic history and that of the early Norman kings of England. In 1562 the Huguenots sacked the abbey and scattered its records; but most of this literary treasure was afterwards wonderfully recovered. Many records were burned along with religious books by the mob in 1793, and the library was again scattered; it was generally supposed that nothing had survived, but in 1829 no fewer than 225 folio and quarto volumes of charters and MSS. were discovered in the town-hall, of which many are preserved in the Bibliothèque Nationale, Paris, and some have found their way to the British Museum. For those relating to England, see Sir G. F. Duckett's valuable *Record-Evidence of Cluni* (1886), and *Charters*

and *Records of Cluni* (1888). See also the works of Pignot, the historian of the order, Lorain, Penjon, Cuchérat, and Champly. The ancient palace in Paris of the Abbots of Clugny became in 1833 a museum of antiquities.

Clumber, a seat of the Duke of Newcastle 3 miles SE. of Worksop. It has given name to a breed of Spaniels (q.v.).

Clunes, a gold-mining township of Victoria, 119 miles NW. of Melbourne. Pop. 4717.

Clupeidæ. See HERRING, SARDINE, SPRAT.

Clusia, a genus of tropical trees and shrubs of the order Clusiaceæ or Guttiferæ (q.v.), some of which are commonly called Balsam trees, from their resinous or balsamic products. They are very often *epiphytes*, growing on larger trees, but also take root in the ground. *C. rosea*, a native of the West Indies and tropical America, yields a resin, which is used as an external application in veterinary medicine, and for covering boats instead of pitch. The abundant resin exuding from the disc of the flowers of *C. insignis*, the Wax-flower of Demerara, is used to make a gently stimulating and soothing plaster. The name was given in honour of the botanist and traveller Clusius, or Charles de Lecluse (1526-1609).

Clustum. See CHIUSI.

Clwyd, a river of North Wales, rises on Craig Bronbanog, in Denbighshire, and enters the Irish Sea after an irregular course of 30 miles. Below Ruthin it flows through the fertile Vale of Clwyd, 24 miles long, and 2 to 7 wide.

Clyde (Welsh *Clwyd*, 'strong'), a world-famous river and firth of south-west Scotland. The river rises as Daer Water at an altitude of 1600 feet, and runs 106 miles northward and north-westward, round Tinto Hill (2335 feet), and past Lanark, Bothwell, Glasgow, and Renfrew, till at Dumbarton it merges in the firth. Its drainage area is estimated by Sir John Hawkshaw at 1481 sq. m., of which 111 belong to the South, North, and Rotten Calder, 127 to the Kelvin, 200 to the Black and White Carts, and 305 to the Leven and Loch Lomond. Tributaries higher up are Powtrail Water, Little Clydes Burn, Douglas Water, Medwyn Water, Mouse Water with its deep gorge through the Cartland Craigs, and, near Hamilton, the Avon. Of these, Little Clydes Burn, rising close to head-streams of the Tweed and the Annan, is often wrongly regarded as the Clyde's true source. In the four miles of its course near Lanark the river descends from 560 to 200 feet, and forms the four celebrated Falls of Clyde—Bonnington, Corra, Dundaff, and Stonebyres Linns, of which the finest, Corra, makes a triple leap of 84 feet. Above the falls the Clyde is a beautiful pure trout-stream, traversing pastoral uplands; below, it flows through a rich fertile valley, here broadening out into plain, there pent between bold wooded banks. But its waters become more and more sluggish, begrimed, and polluted, the nearer they get to Glasgow, where experiments made with floats in 1857-58 showed that the sewage sometimes took a whole week to travel only 2½ miles. Since 1765 upwards of ten millions sterling has been expended on rectifying and deepening the channel from Glasgow to Dumbarton, no less than 32,261,776 cubic yards of materials having been lifted by steam-dredgers during 1844-87. The result has been that whereas 'a hundred years ago there was a depth at low-water of 15 inches, now they have at Glasgow from 18 to 20 feet at low-water;' and that whereas even lighters could once 'not pass to and from Glasgow except it be in the time of flood or high-water at spring-tides,' now a steamer has been docked at Glasgow that

is second in size only to the *Great Eastern*. In 1812 Henry Bell (q.v.) launched on the Clyde the first boat in Europe successfully propelled by steam; and since then the river's shipping and shipbuilding (the latter dating from about 1718) have both grown enormously, 404,383 tons having been launched from the Clyde yards in 1883.—The *FIRTH*, which some make begin at Glasgow (the highest point of the tide), and some not until Gourock, extends 12 miles westward and 52 southward, and broadens from 1 mile at Dumbarton to 1½ at Dunoon, and 37 at Ailsa Craig. It sends off the Gareloch, Loch Long, Holy Loch, and the Kyles of Bute; contains the islands of Bute, Arran, and the two Cumbraes; is bordered along its ancient sea-margin with an almost continuous fringe of seaports and watering-places (Greenock, Rothesay, Ayr, &c.); and, like the last 14 miles of the river, is one of the world's chief commercial waterways. See the reports of Smeaton (1755), Rennie (1799), Hawkshaw (1876), and Deas (1881-87); Dorothy Wordsworth's *Tour in Scotland* (1874); W. J. Millar's *The Clyde from its Source to the Sea* (1888); and Pollock's *Dictionary of the Clyde* (1888). For the 'Clydesdales,' or famous Lanarkshire horses, see HORSE.

Clyde, LORD. See CAMPBELL, SIR COLIN.

Clyster (Gr., from *κλύζω*, 'I wash out'), called also *enema*, a medicine administered in the liquid form by the rectum, or lower end of the intestine. It is used either for the purpose of procuring evacuation of the bowels, or of conveying stimulants (brandy, wine, &c.), other medicines, or nourishing substances into the system. A nourishing clyster, in order to be effective, must be specially prepared or digested by means of pepsin, pancreatin, or some such agent; for the rectum, though it has the power of absorbing food already digested, is not capable of performing the functions of digestion. A nourishing or medicinal clyster must be administered in as small bulk as possible; no more than a wine-glassful should be introduced at one time, or it will probably be rejected. For the purpose of procuring evacuation, on the other hand, as large a quantity should be introduced as possible; simple warm or cold water may be employed, or in special cases, various cathartics may be used in addition, such as colocynth, aloes, castor-oil, or turpentine made into an emulsion with yolk of egg; and sometimes carminatives, to expel air. The introduction of a teaspoonful of glycerine is often very effectual in procuring an action of the bowels when other methods fail. Medicinal clysters should only be used under medical superintendence. An injecting syringe, with a flexible tube and a double-action valve, is usually employed for the administration of remedies in this way.

Clytemnestra, in Homeric legend, the wife of Agamemnon. See AGAMEMNON, ÆSCHYLUS.

Cnidus, or GNIDOS, the chief of the cities of the Doric league in Asia Minor, stood on the promontory of Triopion (now Cape Krio), in Caria, and, with its two harbours, was long a wealthy and flourishing port. Here, in 394 B.C., a great sea-fight took place between the Athenians under Conon, and the Spartans under Pisander, in which the former were victorious. The city was a principal seat of the worship of Aphrodite, who was therefore sometimes called the Cnidian goddess. One of its many temples contained the famous statue in Parian marble of the naked Aphrodite by Praxiteles. Excavations were made on the site in 1857-58, and many of the marbles then recovered are in the British Museum.

Coach-building. See CARRIAGE.

Coach Dog. See DALMATIAN DOG.

Coaching. One of the most remarkable circumstances in connection with this subject is the comparatively short period in which its history is comprised. It might very reasonably have been thought that the exigencies of commerce, no less than those of private requirements, would, even in the earliest times, have demanded a system of communication as speedy as possible, and that some steps would have been taken to secure the desired end. Such, however, scarcely appears to have been the case; and merchants and squires contented themselves with whatever facilities for travel were afforded by the stage-wagon, a cumbersome vehicle drawn at a walk by six, eight, or more horses. Passing over all earlier attempts to organise road traffic, we may come to the year 1659, when the first stage-coach—that from Coventry—was started. Its pace was probably not faster than that of the Oxford coach, which went from London to Oxford in two days, at about 3 miles an hour, or that of the vehicles which occupied two days and a half in compassing the distance between London and Dover. In 1700 a week was required to go from London to York; and two days from London to Salisbury. The first mail-coach was not put on the road until 1784, when Mr John Palmer, manager of the Bath theatre, and M.P. for Bath, overcame strenuous opposition, and induced Mr Pitt to supersede Allen's system of postboys, whose contract rate of speed was 5 miles an hour, by his (Palmer's) plan of carrying the mails by mail-coach. The first experiment was made on the 8th of August 1784, on which day Mr Palmer entered government service as comptroller-general, of the Post-office. A coach left London at 8 A.M. and reached Bristol at eleven at night. The other coach left Bristol at four in the afternoon, arriving in London at eight the next morning, the up journey thus taking sixteen hours, or two hours longer than the down journey. The scheme appears to have worked so well from the beginning, that the municipal authorities of the more important towns soon petitioned for the adoption of Mr Palmer's plan in their districts, and in nearly every instance the request was complied with. It was part of the new scheme that the mails should be timed at each stage, so that they might all reach London at about the same hour; and that the outgoing mail-coaches should start at the same time from the General Post-office. At the outset the regulation pace was 6 miles an hour; but in course of time this was increased until the coaches were rated at 10 miles per hour.

This acceleration, however, was due to causes other than the judgment and enterprise of Mr Palmer, the skill of coachmen and coach-builders, and the employment of better horses. At the period above mentioned the bad state of the roads precluded quick travelling, and although we find that roads were the subjects of legislation as early as 1346, it was not till the days of Macadam and Telford that road-travelling was, so to speak, revolutionised. The former returned to Ayrshire from America in the year 1783, and after studying road-making as a science while one of the road commissioners in Scotland, came south to Bristol in 1816, became surveyor in that district, and was consulted as to the making of other roads in all parts of England. As soon as Macadam's plans were carried into effect, good roads took the place of bad ones; quick travelling commenced, and paved the way for the palmy days of coaching, until, in 1836, there were fifty-four mail-coaches in England, thirty in Ireland, and ten in Scotland. Meantime the stage-coaches had grown in number, travelled at a high rate of speed, and necessitated the employment of a vast amount of capital. Among the best-known London proprietors were Chaplin,

Horne, Sherman, Nelson, and Mountain; the two first named having the judgment to discern that the railways would eventually drive coaches off the road, threw in their lot with the London and Birmingham Railway. It was not till after George IV. came to the throne that coaching reached the zenith of its fame in respect of organisation, pace, appointments, and one may, perhaps, say coachmanship as well. The 'palmy days,' concerning which so much has been written, began about 1820, and coaching was possibly at its most perfect pitch about 1836. For about four years it enjoyed this repute, and then the downward journey, far more rapid than the upward one, began; one by one coaches were taken off; coaching inns became roadside public-houses; coachmen and guards found other occupations, or migrated to the workhouse; stables were emptied, and admiration for coaching gave way to appreciation of railroad-travelling.

Of amateur coachmen and coachmanship in the last century comparatively little is known; but, when good roads were the rule instead of the exception, 'gentleman coaching' became a fashionable amusement. Mr John Warde, the famous master of foxhounds, was a renowned whip, to whom were due the thanks of the old coachmen for having originated the idea of placing springs under the coach-box. The name of Peyton has ever been connected with the annals of the road; the Messrs Walker, Sir St Vincent Cotton, the Marquis of Worcester, Mr Henry Villebois, Mr Maxse, Mr Jerningham, Mr Sackville Gwynne, Sir Bellingham Graham, Mr Stevenson, Hon. Fitzroy Stanhope, Hon. T. Kenyon, Colonel Silthorpe, and Mr C. Buxton are among the number of those who patronised the road by every means in their power. Others, scarcely less enthusiastic, succeeded them, until there were no road-coaches to be driven. So far as London is concerned, the link between the past and present was broken in the year 1858, when the Brighton 'Age,' under the management of Clarke, assisted by the Duke of Beaufort and Sir George Wombwell, was given up; and for eight years there was no road-coach running out of London. But the love for the road was only slumbering, it was not dead; and it was on the Brighton road that the first step was taken in the coaching revival in 1866. In that year Captain Haworth, Captain Laurie, and a few others, started the 'Old Times' to Brighton. At the end of the season the confederacy was broken up, and in 1867 the Duke of Beaufort, Mr Chandos Pole, and Mr B. J. Angel took the road, running a coach each way daily. Between then and the present time coaches have been started to Sevenoaks, Tunbridge Wells, Virginia Water, Dorking, Sunbury, High Wycombe, Westerham, Reigate, Watford, Windsor, Rochester, Guildford, Portsmouth, Maidenhead, &c. Some only lasted a short time, and since the revival began there have been many changes in routes and proprietors. Thus in 1884 only four coaches were left, the Brighton road being vacant; whilst in 1888 there were eight coaches running out of London, and three of them on the Brighton road. From time to time coaches have also been put on in the provinces.

The year 1877 was a somewhat memorable one in the annals of modern coaching, as on 4th November the 'Old Times' was put on to St Albans, and has run every 'lawful day' since without a break, though not always on the same route. In 1888 it was put upon the Brighton road, and on the 11th July James Selby (*ob.* Dec. 1888), its coachman since 1877, drove from Piccadilly to Brighton and back in seven hours fifty minutes, the outward journey being accomplished in three hours fifty minutes and ten seconds. This performance, though a good one, is not a 'record,' as in 1837 Israel Alexander, a pro-

fessional on the Brighton road, drove down with the Queen's first speech in three hours forty minutes.

The meets of the Four-in-hand Driving Club and the Coaching Club are justly regarded as among the sights of the season. The former is the more exclusive as well as the elder, having been established in 1856, chiefly at the suggestion of Mr W. Morritt. The club could not entertain one quarter of the applications for membership, so in 1870 the Coaching Club was established, and has been gradually increasing in size. For the first driving club of which we have any account, we must go back to the year 1807, the date of the establishment of the Bensington Driving Club—the B.D.C. it was generally known as—which was limited to twenty-five members. For the first sixteen years of the club's existence its members used to drive down two days in the season to Bensington; near Wallingford, in Oxfordshire, and twice to Bedford; but in 1823 the Bensington gatherings were given up. A second club was founded in 1808 by Mr Charles Buxton. The new association was called the Four-horse Club; but it was sometimes, though wrongly, designated as the Whip Club, and the Four-in-hand Club. The Four-horse Club was broken up in 1820, was revived in 1822, but became extinct altogether about 1829. The B.D.C. was then the only body of the kind until 1838, when Lord Chesterfield established the Richmond Driving Club, the members of which, after meeting at Chesterfield House, drove to Richmond for dinner. This club, however, came to an end after nine or ten years; and in 1852 the B.D.C. was broken up. From that time there was no driving club until the present Four-in-hand Driving Club was founded as already mentioned. See *Driving*, by the Duke of Beaufort (Badminton series, 1888).

Coadjutor (Lat.), a fellow-worker, not as principal but as second, an assistant. Technically, it is applied in ecclesiastical law to one appointed to assist a bishop, whom age or infirmity has disabled. If a bishop or archbishop is too ill to execute a resignation, the crown may give the dean and chapter power to appoint a bishop-coadjutor.

Coagulation, the amorphous (q.v.) solidification of a liquid, or part of a liquid, as when the casein of milk is solidified by rennet in making Cheese (q.v.), or the white of an egg by boiling. The process varies in various substances. Albumen, or the white of an egg, coagulates at a temperature of 160°. Milk is coagulated or curdled by the action of rennet or by acids. The fibrin in the blood, chyle, and lymph of animals is coagulated by the separation of these fluids from the living body. See **BLOOD**.

Coahuila, a state of Mexico, separated from Texas by the Rio Grande, has an area of 59,280 sq. m., partly mountainous, and forming in the west a part of the wilderness of the Bolson de Mapimi. The climate is healthy, although extremes of heat and cold are usual. The state is rich in minerals, especially silver, and coal has been found. It has valuable pasturage, and in many parts a most fertile soil; but no district of Mexico is so little known, or has been less developed. The construction of the National Railway has, however, prepared the way for a change, and already several cotton-factories and a large number of flour-mills are in operation. Pop. (1882) 144,594. Capital, Saltillo (q.v.).

Coaita. See SPIDER-MONKEY.

Coal, in the sense of a piece of glowing fuel (and hence a piece of fuel, whether dead or alive), is a word common to all the languages of the Gothic stock (A.S. *col*, Icel. *kol*, Ger. *kohle*). The different sorts of fuel are distinguished by prefixes, as *charcoal*, *pit-coal*; but in England, owing to the

absorbing importance of mineral or pit coal, the word coal alone has come to be used in this special signification (Ger. *steinkohlen*, Fr. *charbon de terre*).

Coal is one of the most important of all rocks; it consists chiefly of carbon, and is universally regarded as of vegetable origin. Its geological relations are noticed in the article CARBONIFEROUS SYSTEM. It occurs in layers or beds, and is always of a black or blackish-brown colour. Some of the varieties have a very considerable degree of vitreous or resinous lustre, while others are destitute of lustre; some have a shell-like fracture, and others have a highly cross-jointed structure, and are readily broken into cubical or rhomboidal fragments. The precise characters of coal as a rock species are not easily defined, and both in Britain and other countries important cases have occupied courts of law, in which this difficulty was strongly felt, as in the great Scottish lawsuit concerning the Torbanehill Mineral or Boghead Coal (q.v.). Coal, indeed, is rather a commercial than a scientific term, but in a general way we may define it as a fossil fuel of black colour and stony consistency, which, when heated in close vessels, is converted into coke with the escape of volatile liquids and gases. The variety known as blind coal or anthracite no doubt gives off scarcely any volatile matter, but this is because it has undergone a natural distillation through the action of subterranean heat or of the proximity of intrusive igneous rock. We may therefore divide coal into two primary divisions—namely: (1) *Anthracite*, which does not, and (2) *Bituminous coal*, which does, flame when kindled. Anthracite (q.v.) sometimes contains as much as 94, and if we exclude the ash, 98 per cent. of carbon, and as this element decreases in amount it graduates into a bituminous coal. The term anthracite is, however, still applied to some coals which do not contain more than 80 per cent. of carbon. Various synonyms, such as stone coal, glance coal, culm, and Welsh coal, are also used to designate this substance, which is used chiefly for smelting purposes and for generating steam. In the United States it is also very largely used for domestic purposes—heating and cooking. It is difficult to kindle, but gives out a high heat in burning. Bituminous coal includes an almost endless number of varieties, one of the best marked being *cannel* or *parrot coal*. Cannel coal is probably so called from burning with a bright flame like a candle, and the name parrot coal is given to it in Scotland from the crackling or chattering noise it makes when burned. That of different localities varies much in appearance, but it is most commonly dull and earthy, or with only a slight lustre; some examples are, however, bright and shining. In texture it is nearly always compact, and certain beds of it admit of being polished in slabs of considerable size, which approach black marble in appearance. Of this material vases, inkstands, boxes, &c. are made. Cannel coal contains a large percentage of ash, but the best cannels are in some places much used for open-grate fires in houses. Cannel is for the most part consumed in making gas, of which it yields from 8000 to 15,000 cubic feet per ton. When distilled at a low red-heat it yields paraffin oil. The other varieties of bituminous coal are so numerous that, as an Admiralty report states, there are as many as seventy denominations of it imported into London alone. Still, among these there are three leading kinds—1. *Caking coal*, which cakes or fuses into one mass in the fire. It breaks into small uneven fragments, and is found largely at Newcastle and some other localities. 2. *Splint or hard coal*, occurring plentifully in Scotland, which is hard, and breaks into cuboidal blocks. This is often

called block-coal; and locally it is very valuable, because it can be employed in smelting without being first coked. It is not very easily kindled, but when lighted makes a clear lasting fire. 3. *Cherry or soft coal*, which breaks easily into small irregular cubes, has a beautiful shining lustre, is readily kindled, and gives out a cheerful flame and heat. It is common in Staffordshire. Brown coal or Lignite (q.v.), though for the most part inferior to true coal, is nevertheless an important fuel in some countries in default of a better kind. There are, however, large deposits of lignites in some regions, as in North America, which coke well, and which are excellent substitutes for true coal.

The use of coal does not seem to have been known to the ancients; nor is it well known at what time it began to be used for fuel. Some say that it was used by the ancient Britons; and at all events it was to some extent an article of household consumption during the Anglo-Saxon period as early as 852 A.D. There seems to be reason for thinking that Britain was the first European country in which coal was used to any considerable extent. A coal-pit at Preston, Haddington, was granted to the monks of Newbattle between 1210 and 1219. Henry III. is said to have granted a license to dig coal in 1234. About the end of the 13th century it began to be employed in London, but at first only in the arts and manufactures; and the innovation was complained of as injurious to human health. In 1306 the parliament petitioned the king to prohibit the use of coal, and a proclamation was accordingly issued against it; but owing to the high price of wood, its use soon became general in London. It was for a long time known there as *sea-coal*, because imported by sea.

Several theories as to the mode of the origin of coal have been put forth from time to time. The one now generally believed in is that the rank and luxuriant vegetation which prevailed during the carboniferous age grew and decayed upon land but slightly raised above the sea; that by slow subsidence this thick layer of vegetable matter sunk below the water, and became gradually covered with sand, mud, and other mineral sediment; that then, by some slight upheaval or gradual silting up of the sea bottom, a land surface was once more formed, and covered with a dense mass of plants; which in course of time decayed, sank, and became overlaid with silt and sand as before. At length, thick masses of stratified matter would accumulate, producing great pressure, and this, acting along with chemical changes, would gradually mineralise the vegetable layers into coal. Microscopical examination shows that coal consists principally of the cortical portions of plants—more especially of the bark of such trees as *Sigillaria*—commingled with the debris of various other plants, amongst which the spore cases and spores of certain lycopodiaceous trees not infrequently occur in great abundance. It seems probable indeed that many coal-seams simply represent great swamps and marshy jungles.

As will be seen from the following table, wood, peat, lignite or brown coal, and true coal indicate by their composition the changes which vegetable matter undergoes by decay and pressure; and a table in which a considerable number of examples of each substance could be given would show how gradually these substances pass into each other:

	Wood.	Peat.	Lignite.	Coal.
Carbon	50.0	60.0	65.7	82.6
Hydrogen	6.2	6.5	5.3	5.6
Oxygen	43.8	33.5	29.0	11.8
	100.0	100.0	100.0	100.0

In each of these bodies there is usually a small percentage of nitrogen, which in the above table has not been separated. In passing from wood or peat

to coal, the proportion of oxygen and hydrogen decreases, these substances being given off in the form of marsh-gas and carbonic acid in the process of decay.

On the continent of Europe, productive coal-fields occur in Belgium, France, Prussia, Spain, Silesia, and in Russia—the only important Russian coal-field being that of Donetz, on the north shore of the Sea of Azov. Coal is also found in India, China (where several extensive coal-fields occur, in which coal has been worked from a very early period), Japan, and the Malayan Archipelago, in Australia and New Zealand, and in Africa. There is evidence of promising coal-deposits in several South American countries, but, owing to the great supply of wood in their forests, there is little temptation to work them. Considerable importance already attaches, however, to the mines of Chili (q.v.). In Canada there are small, though valuable, coal-fields; but in the United States enormous fields of fossil fuel are found. The entire area of these is about 200,000 sq. m., being 83 times greater than the area of the coal-fields of Great Britain. But although the coal-measures of the States are of vast extent, and contain many valuable coal-seams—a few of them 40 and even 50 feet thick at certain places—it has been doubted whether the amount of workable coal in them has not been exaggerated. In proportion to the extent of the seams, the quantity of coal annually raised in the States is small, and amounted to 112,743,403 short tons of 2000 lb. each in 1886. The distribution of the coal-fields of Britain and North America is discussed at CARBONIFEROUS SYSTEM.

Coal-supply of Britain.—The probable duration of the British coal-supply is a question which until recent years rarely excited any public anxiety. Early in the 19th century attention had been called to the subject by Sir John Sinclair, Mr Robert Bald, and Dr Buckland, but the existing store of coal was generally believed to be practically inexhaustible—its exhaustion at all events seemed to be relegated to so remote a date as to relieve the nation from all anxiety on the matter. In recent years, however, Professor Hull, from a more accurate survey of British coal-fields than was possible before the map of the Geological Survey had been published, came to the conclusion in 1860, that at the then rate of production we had enough coal to last for 1000 years. But as the rate of consumption was yearly increasing, it was obvious that our coal-supply might not last nearly so long. In 100 years, as Professor Jevons showed, if the same rate of increase continued, the annual consumption would be 415,000,000 tons, and our coal-fields by that time would be nearly exhausted. A Royal Commission was appointed in 1866 to consider the whole question, and came to the conclusion in 1871 that at the then rate of consumption there was enough coal to last for 1273 years, but with a constantly increasing consumption this term would necessarily be reduced. The amount of coal at all depths down to 4000 feet was estimated at the date of the Royal Commissioners' Report to be 90,207 million tons, while including the coals at greater depths, the total was 146,480 millions of tons. Although, therefore, we know approximately the extent of available coal, we cannot tell how long that coal will last, for we cannot say whether the present rate of consumption will be maintained, increased, or diminished in the future. It seems most probable, however, that the rate of increase of coal used per head of the population will follow a diminishing ratio, and that it will be 300 or 400 years before the coal-supplies of these islands begin to fail.

Coal-trade.—The production and sale of coal, like every other important branch of industry, was long

fettered with legislative regulations. At a very early period, the corporation of the city of London undertook the duty of either weighing or measuring the coal brought into the port, and by a series of statutes commencing with 7 Edward VI. chap. 7, the mayor and aldermen of London, and the justices of the counties, were empowered to fix the price of coal to be sold by retail; and in case of refusal by the parties to sell at the prices fixed, to enter their wharves, or other places of deposit, and to cause it to be sold at the prices which they had set. In addition to the general supervision which they thus possessed, and the sums which they were empowered to exact for their trouble, the corporations of London and other towns have exacted, and still continue to exact, dues on coal for local purposes. These were first imposed in London in 1667, after the great fire, in order to enable the corporation to repair the ravages which it had committed; and they have been since continued as a fund for civic improvements, though, as McCulloch has remarked, no improvement could be equal to a reduction in the price of coal. In the reign of William III. a general tax, payable to government, was laid on all *sea-borne coal*—a tax which was in the highest degree unjust to places which were dependent for their supply on the coasting trade, and oppressive to the whole country, inasmuch as it amounted to more than 50 per cent. on the price paid to the owner at the pit's mouth. The tax varied in amount, not only at different periods, reaching its highest point of 9s. 4d. per chaldron during the great war, but also in different parts of the country, being higher in London and the south of England, and lower in Ireland and Wales, whilst Scotland for a considerable period was altogether exempt. The tax itself, with all its inequalities, was abolished in 1830, and there is now no tax on coal except that collected for local purposes in London, and a few other towns. The repeal, in 1845, of the duty on coal exported to foreign countries, was a measure of much more doubtful policy. The average annual quantity of coal exported from Great Britain during the three years ending 1886 was above 22,000,000 tons.—For the regulation and inspection of mines, explosions, &c., see MINING. The circumstances in which coal-mines are regarded as a pertinent of land, and those in which they form a separate estate, are stated under MINES. The condition of colliers and salters in Britain is discussed at SERF. For coal-tar products, see COAL-TAR.

Coal-whipping is the name given to a mode of unloading coal from vessels at anchor to barges, which convey them to the wharves. When the number of these men at work on the Thames was about 2000, public-house keepers got into the habit of acting as middlemen; the trade fell into such a state, that the men were virtually slaves to the publicans. They asked for the interference of the legislature. An act was passed in 1843, and a Coal-whippers' Board was formed, which contracted for the whipping of ships of coal, and employed the men. This exceptionally-protected trade was maintained on the same basis by other acts passed in 1846 and 1851. In 1856, however, a further renewal was refused. The coal-owners agreed with the Board of Trade to maintain a Whipping Office, to give the men a refuge from the publicans, but without interfering with the liberty of coal-shippers to employ whom they pleased; and this plan was afterwards acted on. The necessity for coal-whippers has been much lessened of late years, owing to the almost universal use of hydraulic or steam machinery in discharging. See Green and Miall, *Coal: History and Uses* (1878); Galloway, *History of Coal-mining in Great Britain* (1882); Hull, *Coal-fields of Great Britain* (1880).

Coalbrookdale is a district in Shropshire, extending 8 miles along the river Severn; its coal-field supplies coal and iron as well as limestone, and manufactures iron. The village of Coalbrookdale, which gives it name, is 11 miles SE. of Shrewsbury.

Coal-fish (*Gadus carbonarius*), a species of cod, with black upper parts, common in northern seas. It occurs from 80° N. lat. to the Mediterranean, and is common off North American and British coasts. In Scotland it is often called Saith. It often measures 2 to 3 feet in length, and may be considerably larger; occurs in great shoals; is exceedingly voracious. Though decidedly coarse, its flesh is much eaten in northern parts. The young ones are often caught by boys fishing off the rocks, and are variously known as podleys, sillocks, cuddies, and coalseys. See COD.

Coaling Stations. The question of coaling stations has of late engaged a large share of public attention in Britain. The necessity for maintaining a sufficient number of fortified outposts on the great lines of British trade has been recognised by successive governments, and the work of defence has, after a regrettable delay, at length been vigorously taken in hand. The inquiry by a Royal Commission resulted in the publication in 1881-82 of an exhaustive report, from which the present article has been compiled.

The Commissioners estimated the value of British ships and the freights which they carried annually at £900,000,000, British property to the value of £144,000,000 being at all times afloat, the greater part on distant voyages. Broadly, the foreign trade of the United Kingdom may be divided into two great divisions—the trade with the Americas, and that with the Mediterranean, the East, and Australia, by the Suez Canal and the Cape. It is chiefly with the latter that we are here concerned.

On the great trade-route by the Suez Canal to India and to Australia, steamships have entirely superseded sailing-ships. It is along this route that the possession of a continuous chain of coaling stations gives Britain an advantage which it is imperatively necessary to maintain. The Cape route, again, is essential to the retention by Great Britain of her possessions in India, Ceylon, Mauritius, Singapore, China, and Australia. It is by this route that reinforcements of troops and necessary supplies could, in the contingency of war, be despatched to the East with the least exposure to capture.

It must be accepted as a leading principle that the defence of harbours should be secured by forts and not by ships. The Royal Navy is not maintained for the purpose of affording direct local protection to seaports and harbours, but for the purpose of blockading the ports of an enemy, of destroying his trade, attacking his possessions, dealing with his ships at sea, and preventing an attack in force upon any special place. It is by the efficient performance of these duties that British commerce and colonies will be best protected.

The great fortresses of Gibraltar and Malta are maintained wholly from resources provided by the imperial exchequer. Improvements in their defences have been going forward ever since they came into the possession of Britain; and it may be assumed that Gibraltar and Malta are well prepared to resist attack. For the manning of the works strong garrisons of 6000 men are permanently maintained.

Pursuing our way through the Suez Canal, which, in consequence of recent political changes, has practically passed under British control, we find at Aden another commanding position. The distance from Suez is 1300 miles, from Mauritius

1970, from Bombay 1637, and from Ceylon 2130. Aden is not only an important coaling station in peace-time for ships using the Suez Canal, but, in the event of war with any of the Mediterranean powers, it would be the only place in possession of Britain from which a fleet could prevent foreign ships of war, that had passed through the canal into the Red Sea, from gaining access to the Indian Ocean. The Royal Commission urge strongly that Aden should be made secure against the attack of a small naval squadron.

Bombay is much more than a mere coaling station. It is the greatest port of India, and one of the busiest entrepôts of commerce in the world. The harbour, defended by batteries and by two armoured vessels, was declared by Sir Frederick Richards, when naval commander-in-chief on the East India station, to be sufficiently secured against any probable attack.

Kurrachee is a post of immense importance as the base for the military defence of the north-west frontier of India. As compared with Bombay, Kurrachee is nearer to England by two days' steaming. By skilful engineering, the entrance to the port, the anchorage, and the wharfrage have been adapted to the requirements of steamships of large tonnage. The defences, both by batteries and torpedoes, are well advanced.

The distance from Ceylon to the Cape of Good Hope is 4400 miles, from Mauritius 2100, from Aden 2130, from Bombay 960, from Singapore 1510, and from King George's Sound 3400. If measures are taken to prevent an enemy's ships from coaling in the adjacent seas, Ceylon will be comparatively safe from heavy attacks. The possibility of attack by a hostile cruiser must, however, be admitted. The Commissioners carefully weighed the relative advantages of Galle, Colombo, and Trincomalee. Galle, for many years the port of call for mail-steamers, has gradually been abandoned in favour of Colombo. The latter port has a commodious harbour, already sufficiently advanced to afford well-sheltered anchorage during the south-west monsoon. For local reasons, no less than for imperial considerations, the Royal Commission held it necessary that Colombo should be adequately protected, both by floating defences and by batteries on shore. Trincomalee is the safest and most commodious harbour in the Indian Ocean, and very capable of defence. But it is out of the course of trade, and has no facilities for the repair of ships; so the Commissioners did not recommend a large expenditure on fortifications at Trincomalee.

Singapore is the next important position in the possession of Great Britain. The annual value of the imports and exports exceeds £8,000,000. In 1880 the quantity of coal supplied to passing steamers had already reached a total of from 12,000 to 15,000 tons a month. Extensive wharves, three graving-docks, and all the appliances for repairing ships, have been provided by private enterprise. The colonial government have carried out an extensive scheme of defence, planned by officers of the Royal Engineers. The torpedo defences are complete.

Hong-kong is the chief centre of British trade with China, and the only dependency from which that trade can be defended. The entries of shipping in 1880 included 26,801 vessels, with an aggregate burden of 4,185,000 tons, and manned by 421,887 hands. Graving-docks exist in the hands of commercial companies, capable of receiving ironclads of the largest class which will be seen in the China Sea. The defence of the harbour is now being made good at the cost of the local and imperial governments. A small ironclad is stationed at Hong-kong for the defence of the harbour.

To the Cape of Good Hope, the distance from

England is 6000 miles. The intermediate coaling stations now used are Lisbon, Gibraltar, Madeira, St Vincent, and Sierra Leone. Lisbon, Madeira, and St Vincent being in foreign territory, Sierra Leone is the first British coaling station. The harbour is capacious and secure, and the works for its defence are nearly completed. Ascension, distant from Sierra Leone 1000 miles, from St Helena 680 miles, and from the Cape of Good Hope 2380 miles, has a roadstead, or landing-place, on its west or leeward side; there is no harbour. Ascension has been used as a dépôt for stores and the supply of coals. By a wise decision of the Admiralty (1887) the stores were to be removed from Ascension, which was henceforth to be used only as a sanatorium for the benefit of ships whose crews have suffered from fever.

St Helena, in the opinion of the Royal Commission, has many advantages over Ascension. It is larger, has a cooler temperature, more vegetation, and a better roadstead. Within a recent period £30,000 has been expended on fortifications; and it has been decided to further strengthen the defences, and to supply a modern armament.

The Royal Commission showed that the value of British trade either with the Cape of Good Hope, or passing round it, amounted to £91,352,000 annually, the whole, with the exception of about £4,000,000, being carried on directly with the United Kingdom. Enormous, however, as is the value of this trade, it by no means represents that which, in the event of war with one or more of the great naval powers, might pass round the Cape. The annual value of British trade with India, Ceylon, China, and the East, conveyed through the Suez Canal, falls little short of the trade by the Cape route. If the long sea-route became alone available, the annual value of the traffic by the Cape would amount to £150,000,000, exclusive of that of the shipping employed. The Cape peninsula, about 32 miles in length, is a rugged mountainous district, connected with the continent by a low isthmus, 13 miles in length (see map of CAPE COLONY). Simon's Bay affords a secure anchorage, and naval establishments have been formed on its shores. The anchorage in Table Bay, the scene of many disasters in former days, has been rendered secure by a noble breakwater. Docks have been formed. The graving-dock is capable of receiving large ironclads. To make the Cape thoroughly secure, it is necessary to fortify both Table Bay and Simon's Bay. The defences at Simon's Bay have been completed at the sole cost of the imperial government. At Table Bay the works are being executed by the colony, while the armaments are provided by the imperial government.

Mauritius lies nearly midway between the Cape and India, 4440 miles apart. The colony has a trade of the annual value of £6,000,000. Port Louis is a safe and commodious harbour. The Royal Commission recommended additions to and improvements of existing defences. The torpedo defences are complete.

Having dealt with British trade with the East, we turn to the West. The trade of the United Kingdom with the United States and Canada exceeded, at the date of the Commissioners' report, £119,000,000 in annual value. The largest proportion is food and raw material supplied to the United Kingdom. War with the United States cannot be contemplated by practical British politicians. In the event of war with any other power, merchant-steamers would require protection only near the coast at either end of their voyage, trusting to their own speed for the intermediate portion.

British trade with the West Indies amounts

annually to £21,000,000. The defence of this important trade rests on Jamaica and St Lucia. The defences of Jamaica have been modernised and greatly improved in recent years. St Lucia has been selected by the Admiralty as a coaling station for the fleet in the Windward Islands.

It is not necessary to refer in detail to the land defences of the great ports of Australia. The combined expenditure of the several governments may literally be reckoned by millions. The manning of the works and the general defence of the colonies by land is guaranteed by an army of more than 30,000 volunteers, of splendid physique, well equipped, and provided with a small staff of officers from the imperial service. A considerable flotilla for harbour defence has been created at Melbourne. Adelaide has a powerful coast-defence vessel. Brisbane has two efficient gunboats. Naval brigades have been organised both in Victoria and New South Wales.

New Zealand is secured by its geographical position from an attack in force. The defence of a few principal ports has been taken in hand, under the able advice of Sir William Jervois. A considerable body of volunteers, both for the sea and the land service, has been enrolled.

By an arrangement concluded by the administration of Lord Salisbury, a joint agreement has been entered into, with the approval of the legislatures in the Australias and at home. Under its provisions, by a colonial contribution from the several governments, a special squadron of highly efficient cruisers has been built for the defence of trade in Australian waters and on the coasts of New Zealand. --

Coalition, in Politics, is applied to the union of two parties, or, as generally happens, portions of parties who agree to sink their differences, and act in common. Pitt the elder, when he took office in 1757, coalesced with the Whig aristocracy represented by the Duke of Newcastle. The ministry always spoken of, however, as the Great Coalition was formed in 1782, when Fox, the leader of the reformers, took office along with Lord North, the leader of the opposite party. When Lord Derby's ministry resigned in 1853, there was a short coalition between the Whig party under Lord John Russell, and the more moderate of the Conservative party under Lord Aberdeen. The arrangement made between Conservatives and Liberal Unionists in 1886 can scarcely be called a coalition, inasmuch as the main responsibility of government rests on the former, while the latter give them a general support. The term is also used of alliances between separate states.

Coal-tar, or **GAS-TAR**, is a thick, black, opaque liquid, which comes over and condenses in the pipes when coal or petroleum is distilled. Now usually obtained in the manufacture of gas, tar was about 1782 extracted from coal by the ninth Earl of Dundonald under a patent, expressly for the purpose of being used for protecting ships from rotting. Coal-tar is slightly heavier than water, and has a strong, disagreeable odour. The amount of tar so obtained of course varies with the nature of the coal employed, but it is also dependent on the average temperature of distillation. With a low temperature, a large quantity of tar is produced, along with a small yield of a highly illuminating gas. At first this tar was regarded as a waste product, or, at most, as a source of pitch; but it soon became apparent that as a source of Benzene (q.v.), and through it of the Aniline Dyes (q.v.), it was a commodity of great commercial value.

When coal-tar is distilled, a large number of volatile substances pass over as the temperature

risks higher and higher. At first various gases, ammonia and naphtha, are obtained to the extent of about 1/4th part of the original tar, and then distillation ceases, although the temperature gradually rises. After a period of about an hour, more oils, like the former, lighter than water, are obtained, and so on the distillation proceeds, with successive intervals, yielding what are known as creosote oils, and finally Anthracene oils, the residue in the still being pitch.

At first, when anthracene was of little importance, distillation was not pushed so far, and the anthracene oils were allowed to remain in the pitch; but since the discovery of the process for making artificial Alizarin (q.v.), the heat is pushed as far as possible consistent with the production of a pitch that will sell. The first light oils yield chiefly benzol, carbolic acid, and naphtha. The creosote oils yield creosote and naphthaline, while the anthracene oils produce anthracene and lubricating oils.

After this enumeration of the chief coal-tar products, it will be possible to realise the great importance of this substance. The naphtha, besides being used as a solvent for india-rubber and gutta-percha, is burned to produce a fine variety of carbon for printing-ink. The benzol, including in this term many nearly allied substances, not only yields many brilliant dyes, but is used for cleaning gloves, silks, &c., and other articles which would be injured by washing. The creosote in its crude form is largely used for preserving wood, enabling it to be exposed in damp situations without rotting, while, when burned, its smoke yields lampblack. The naphthaline, besides being a source of many dyes, is employed in the Albo-carbon light to give to ordinary coal-gas very high illuminating power. Finally, the residual pitch is in constant requisition for making roofing felt and asphalt pavement. Besides these primary products of coal-tar, there are of course numerous compounds derived more or less remotely from it. Such are the aniline dyes, the quinine substitutes, antipyrin, antifebrin, &c., and the sweetening substance, Saccharine (q.v.), which may be used to replace sugar in many cases. For further references, see ANILINE, ALIZARIN, BENZENE, CREOSOTE, and NAPHTHALINE; also Lunge's *Coal-tar and Ammonia* (1887).

Coalville, a village of Leicestershire, 16 miles NW. of Leicester by rail. Pop. 1904.

Coanza, a river of West Africa, rising in the east of Benguela, and after a generally NW. course, entering the Atlantic about 30 miles S. of St Paul de Loando, by a mouth over a mile broad. It is navigable for light vessels as far as the Cambaube cataracts, over 120 miles, and is regularly traversed as far as Dindo, a few miles below, by the trading vessels of a steamship company established by the Portuguese, who have many settlements on the banks.

Coast Defence. The character of the defence provided for the coasts of a state must depend on the nature of the coast and of the attack to be anticipated. In Germany a solution of the problem has been sought mainly by means of submarine mines, associated with a strong flotilla of torpedo-boats, and, in certain spots, with powerful batteries. Italy intrusts the defence of her coasts chiefly to her very powerful fleet of ironclads, which can move from place to place as required. In France and England all these methods are employed: mine-fields, which to be effective must be protected by artillery; torpedo-boat flotillas; batteries; and a strong fleet of heavy ships, some of which have been specially designed for this purpose, though their usefulness has been much questioned. In Italy the unusual feature of 120-ton guns mounted in

gun-barges, to take part in the defence of certain important harbours, is also to be noticed. As a general defence against an attack in force, strong batteries in connection with mine-fields offer, perhaps, the best security. Against depredations by isolated ships or cruisers, well-placed guns on the disappearing system, with some fast torpedo-boats, would probably be most efficacious. The question of the best system of defence, under the great changes which have taken place in the material of warfare, must probably remain undecided until more experience has been gained.

Coastguard, an organisation formerly intended to prevent smuggling merely, but now constituted so as to serve as a defensive force also. The old coastguardsmen were in the employment of the Customs department; they were posted along the shore at spots commanding extensive views of the beach, and were expected to be always on the lookout for smugglers. In 1856 the coastguard was transferred to the Admiralty, and under this arrangement the Admiralty may, from time to time, issue orders for the augmentation of the coastguard, not to exceed 10,000 men in all. Lands not exceeding three acres each may be bought by the Admiralty for coastguard stations. The coasts of the United Kingdom have been divided into eleven districts. Each district is under a navy captain, who has an ironclad guardship at some port in the district. All the revenue cruisers and defence-gunboats are attached as tenders to the ships, and are manned therefrom. The able seamen, borne on the ships' books, and employed on shore in coastguard service, are in three classes—chief boatmen, commissioned boatmen, and boatmen. They receive high-sea pay, besides 1s. 4d. per day in lieu of provisions, and house-rent and medical attendance free. In war-time, all of these men may be called upon to serve as regular sailors on board ship; but their families are allowed to live rent-free during this time. The coastguard are taught naval gunnery, gunboat exercise, and the serving of land-batteries. The guardships are also employed as training ships for the navy. The whole of the coastguard comprised, in 1888, 4000 men; and the charge for their maintenance and that of their ships is about £460,000.

Coast Range, a range of mountains nearly parallel to the Pacific Coast in California (q.v.).

Coast Survey of United States. See CHART.

Coatbridge, a thriving manufacturing town in Lanarkshire, 9 miles E. of Glasgow by rail, and 32 W. by S. of Edinburgh. The centre of a great mineral district, it is surrounded by numerous blast-furnaces, and produces malleable iron, boilers, tubes, tin-plate, firebricks and tiles, and railway wagons. Coatbridge has grown very rapidly in size and prosperity—a growth largely due to the development of the Gartsherrie Iron-works of Messrs Baird (q.v.), first put in blast, 4th May 1830. Pop. (1831) 741; (1851) 8564; (1871) 15,802; (1881) 18,425. In 1885 Coatbridge was made a municipal burgh. See A. Miller's *Rise and Progress of Coatbridge* (Glas. 1864).

Co'ati, or COATI-MUNDI (*Nasua*), a genus of the raccoon family (Procyonidae), in the bear-like section of Carnivora. There are two species found in Mexico, Central America, and South America. They live on trees, feeding somewhat omnivorously, and grubbing with an upturned flexible snout. They are social in their habits, and readily adapt themselves to domestication. See RACCOON.

Coat of Arms. See HERALDRY.

Coatzacoalco, a river of the isthmus of Tehuantepec in Mexico, rises in the Sierra Madre, and falls into the Gulf of Mexico, 130 miles S.E. of

Vera Cruz. It is navigable for large vessels for 30 miles, and is interesting as part of a route which has been surveyed for an interoceanic canal.

Cob. See HORSE.

Cobalt (sym. Co, eq. 59, from *Cobalus*, 'a malicious sprite' or 'gnome') is a metal the ores of which are sparingly distributed. In the metallic state it is found in meteoric stones or aerolites to the extent of one per cent., but it generally occurs combined with arsenic as *Speiss-cobalt*, CoAs_2 , or as cobalt-glance, the arsenide and sulphide of the metal, CoSAs . To obtain the metal itself from its ores is a matter of some difficulty, and although it is more tenacious than iron, yet it has not been applied to any practical use. It is of a gray colour with a reddish tinge, brittle, hard, and very magnetic. Many of its compounds are valued on account of the brilliance and permanence of their colours. The Protoxide of Cobalt, CoO , is employed as a blue pigment in porcelain-painting. *Zaffre* is the impure oxide obtained by partially roasting cobalt ore previously mixed with two or three times its weight of fine sand. *Smalt* is the term applied to a deep-blue glass, which owes its colour to the presence of oxide of cobalt, and which, when reduced to very fine powder, is employed occasionally by laundresses to correct the yellow colour of newly-washed linen, and by paper-makers as a blue pigment for staining writing-paper. *Smalt* is also used in the production of the blue colours in porcelain, pottery glass, encaustic tiles, fresco-painting, &c., and forms the principal ingredient in *Old Seves Blue*, *Thenard's Blue*, *Turquoise Blue*, &c. (see BLUE). A compound containing the oxides of cobalt and zinc is of a beautiful green colour, and is known as *Rhman's Green*. The chloride of cobalt dissolved in much water, may be employed as a sympathetic ink. In dilute solutions, it is of a faint pink colour, which is not observable when it is used for writing upon paper; but when heated before the fire, it loses water, and becomes blue, and the writing is then capable of being read. On allowing the paper thereafter to lie in a damp place, or exposing it to the vapour of steam from a kettle, water is again absorbed, and the writing returns to its invisible state. The addition of a little perchloride of iron to the ink makes the writing appear green; a solution of zinc imparts a red tint; and a salt of copper, a yellow shade.

Cobán, capital of the department of Vera Paz, in Guatemala, on the fertile Tierra Templada plateau, about 85 miles N. of the town of Guatemala. Pop. (1880) 18,076.

Cobbe, FRANCES POWER, author, born near Dublin, 4th December 1822, was educated at Brighton, and early had her interest aroused in theological questions. Her mother's death drove her for spiritual help to Theodore Parker, whose counsels are contained in his famous *Sermon of the Immortal Life*. She travelled in Italy and the East, and published her observations in *The Cities of the Past* (1864), and *Italics* (1864). She is a strong Theist, a supporter of women's rights, and has taken a prominent part in the anti-vivisection crusade. Among her works are *Friendless Girls, and How to help Them* (1861); *Broken Lights: an Inquiry into the Present Condition and Future Prospects of Religious Faith* (1864); *Studies New and Old* (1865); *Criminals, Idiots, Women, and Minors: Is the Classification Sound?* (1869); *Darwinism in Morals* (1872); *The Hopes of the Human Race Hereafter and Here* (1874); *Re-echoes* (1876); *The Peak in Darien* (1882); and *The Scientific Spirit of the Age* (1888).

Cobbett, WILLIAM, born at Farnham, Surrey, on 9th March 1762, was the son of a small farmer,

and grandson of a day-labourer. From scaring crows the boy rose to be ploughman; but a visit to Portsmouth and a sight of the fleet had spoiled him for farming, when, in May 1783, a sudden freak took him to London. He reached it with just half-a-crown, and for nine months was quill-driver to a Gray's Inn attorney. Enlisting then in the 54th Foot, he first spent a year at Chatham, where he mastered Lowth's *English Grammar*, and read through a whole lending library—Swift's *Tale of a Tub* had been his boyhood's delight. Next he served as sergeant-major in New Brunswick (1785–91), meanwhile saving 150 guineas, and studying rhetoric, geometry, logic, French, and fortification. On his return he obtained a most flattering discharge; in February 1792 married; but in March went to France to get out of a court-martial on three of his late officers, whom he had taxed with speculation. Six months later he sailed for America. At Philadelphia he taught English to French refugees (Talleyrand wanted to be one of his pupils); translated from the French; and, as 'Petes Porcupine,' wrote fierce onslaughts on Dr Priestley, Tom Paine, and the native Democrats. Twice he was prosecuted for libel, and America got too hot for him, so in June 1800 he returned to England. The Tories welcomed him with open arms; and in 1802 he started his famous *Weekly Political Register*, which, with one three-months' break in 1817, continued till his death. But, Tory first, it altered its politics in 1804, till at last it 'became the most fierce and determined opponent of the government, and the most uncompromising champion of Radicalism.' A great lover of the country, Cobbett settled at Botley in Hampshire, where he planted, farmed, and went in for manly sports; a true soldiers' friend, he got two years in Newgate (1810–12), with a fine of £1000, for his strictures on the flogging of militiamen by German mercenaries. In 1817 money muddles and dread of a second imprisonment drove him once more across the Atlantic. He farmed in Long Island, writing all the while for the *Register*, till in 1819 he ventured back again, and came bringing Tom Paine's bones—the one really silly action of his life. Botley had to be sold, but he started a seed-farm at Kensington; and bent now on entering parliament, stood for Coventry (1821) and Preston (1826). Both times he failed; but his ill-advised trial for sedition (1831) was followed next year by his return for Oldham to the first Reformed parliament. His career there, if not quite a failure, was signalised chiefly by a crack-brained attack on Peel; anyhow, the late hours were too much for him, and on 18th June 1835 he died at Normanby farm, near Guildford. He was buried at Farnham.

Coarse, virulent, braggadocio, inconsistent—Cobbett was all this. He was often right, but he must have been oftener wrong, for oftener he came to abuse what once he had eulogised than *vice versa*. He was a very Ishmael of politics; Lord Dalling dubs him 'the contentious man.' Still, a man he was, a genuine John Bull; and if he wrote nonsense about Waterloo and the national debt, and more nonsense than sense about the Reformation, he wrote it in fine strong English. He loathed Whigs and 'mock gentlefolks,' but he honestly loved the poor—loved Nature, too, and could paint her dear English scenery with a freshness and insight wholly and solely his own. The *Rural Rides* (new edition, with notes by Pitt Cobbett, 1885) are unsurpassable. They were a reprint (1830) from the *Register*, and followed or were followed by *Porcupine's Works* (12 vols. 1801), the excellent and entertaining *English Grammar* (1818), the savage *History of the Reformation* (1824–27), the *Woodlands* (1825), the shrewd, homely *Advice to Young*

Men (1830), and forty or fifty more works. Cobbett was further the originator of Hansard's *Debates* (1806), and of Howell's *State Trials* (1809). See Lord Dalling's *Historical Characters* (5th ed. 1876), and Edward Smith's *Life of Cobbett* (2 vols. 1878).

Cobbold, THOMAS SPENCER, writer on parasitic worms, was born at Ipswich in 1828, studied medicine at Edinburgh, lectured in London on botany, zoology, comparative anatomy, geology, and helminthology, in connection with various hospitals and colleges, and died 20th March 1886. He wrote *Entozoa* (1864), *Parasites* (1879), *Tapeworms* (1866), and numerous other works on kindred subjects.

Cobden, RICHARD, a great English politician, 'the Apostle of Free Trade,' was born at Heyshott, near Midhurst, Sussex, 3d June 1804. His father, a thrifless yeoman, had to sell his farm in 1814, and relations charged themselves with the maintenance of the eleven children; Richard, the fourth, being sent to a 'Dotheboys' school in Yorkshire. After five wretched years there, in 1819 he was received into a wholesale warehouse in London, belonging to his uncle, where he soon showed great aptitude for business, and as a commercial traveller he visited Scotland and Ireland. In 1828 Cobden and two of his friends entered into a partnership for selling calicoes by commission in London. They set up an establishment for calico-printing in Lancashire in 1831, and in 1832 Cobden settled in Manchester, the town with which his name is so closely associated. He wrote a comedy which was rejected by the manager of Covent Garden Theatre. In 1835 he visited the United States, and in 1836-37 travelled in Turkey, Greece, and Egypt. The result of his travels appeared in two pamphlets, *England, Ireland, and America* (1835), and *Russia* (1836); the latter intended as an antidote against the 'Russophobia' then prevalent. In these pamphlets he also ridiculed the workings of diplomacy, and asserted England's mission to be the avoidance of war and the extension of commerce. He contested the borough of Stockport unsuccessfully on free-trade principles in 1837. In 1838 he carried in the Manchester Chamber of Commerce a motion to petition parliament for the repeal of all duties on corn. In the same year seven merchants of Manchester formed the association which soon grew into the Anti-Corn-law League. Of this League Cobden was the most energetic and prominent member. His lectures all over the country, and his speeches in parliament (to which he was returned in 1841 by the constituency which had rejected him in 1837), were characterised by clear, quiet persuasiveness; and to them was in great part due, as Sir Robert Peel acknowledged, the abolition of the corn laws at so early a period as 1846.

Cobden's zeal for free trade in corn had, however, to such a degree withdrawn his attention from private business, that he was now a ruined man, and a subscription of £80,000 was raised in recognition of his great services; and with this in 1847 he re-purchased Dunford, the farmhouse in which he was born. As his health, too, had suffered, he re-visited the Continent, and during his absence was elected both for Stockport and the West Riding of Yorkshire. He chose the latter constituency, which he continued to represent till 1857. He shared Mr Bright's unpopularity for opposing the policy that led to the Crimean war; and on an appeal to the country by Lord Palmerston to support him in his Chinese policy, of which Cobden was a strenuous opponent, he retired from the West Riding and contested Huddersfield, where, however, he was defeated. Cobden spent his leisure in a second American tour. During his absence he was elected for Rochdale.

Lord Palmerston, who was at this time forming his ministry of 1859-65, with a just appreciation of Cobden's great services, offered him a seat in the cabinet as President of the Board of Trade; but Cobden, as the uncompromising opponent of Palmerston's policy, felt bound to decline the honour. After his election for Rochdale, the state of his health did not permit him to take any part in parliamentary proceedings, but as Her Majesty's plenipotentiary, he (1859-60) arranged and concluded the treaty of commerce with France. Cobden spoke out strongly in favour of the North during the American civil war, and in 1864 strenuously opposed intervention in favour of Denmark. He died in London, April 2, 1865, and was buried at Lavington, Sussex. Few politicians have had such an honourable record as Cobden. In all the relations of life he was amiable, single-minded, and earnest. In parliament and on the platform he was a master in the art of clear, persuasive, and convincing speech. He may be regarded as the representative man of the Manchester school, and therefore as the most prominent champion of free trade, peace, non-intervention, and economy. His *Speeches on Questions of Public Policy* were edited by John Bright and Thorold Rogers (1870). See the articles CORN LAWS and FREE TRADE; and his Life by John Morley (2 vols. 1881).

Cobet, CAREL GABRIEL, a learned Dutch Hellenist, born at Paris in 1813, studied at Leyden, next made a long archaeological journey at government cost, and settled in 1847 to a chair at Leyden. One of the most sagacious and acute of modern critics in the department of Greek scholarship, Cobet has published many books and papers of the highest value. These include *Oratio de Arte Interpretandi* (1847); collections of *Varia Lectiones* and *Miscellanea*; works on the comic poet Plato, Dionysius of Halicarnassus, and Xenophon; and editions of Diogenes Laertius, Xenophon's *Anabasis* and *Hellenica*, Lysias, and Cornelius Nepos (1881).

Cobham, LORD. See OLDCASTLE.

Cobija, a seaport of the Chilian province of Antofagasta (q.v.), on a shallow, open bay. See ATACAMA.

Coble. See BOAT.

Coblenz, or KOBLENZ, a city of Rhenish Prussia, 56 miles SSE. of Cologne by rail, is beautifully situated at the junction of the Rhine and the Moselle, the former of which is here crossed by a bridge of boats, and the latter by a fine stone bridge, built originally in 1344. Both rivers are also spanned by railway bridges. Coblenz is very strongly fortified with a wall and a series of detached forts, including the almost impregnable castle of Ehrenbreitstein (q.v.), on the opposite side of the Rhine. In the old town, many of the streets are irregular, narrow, and dirty; but the new town, which is situated nearer the Rhine, is handsomely built, spacious, and clean. Among the principal buildings are the church of St Castor, the oldest Christian church in the Rhine district, founded in 836, though dating in its present form from the 12th century; the Kaufhaus (1479); the Protestant Florins Kirche (12th century); the church of Our Lady (1250-1431); and the old Jesuit College, now a gymnasium. The extensive palace was built in 1778-86 by the last Elector of Trèves, and restored in 1845. The old archiepiscopal palace is now a factory. The favourable position of the place secures it an active commerce in wine, corn, mineral waters, &c. It manufactures champagne (about 1,000,000 bottles annually, exported chiefly to England), cigars, japanned goods, and furniture. Pop. (1875) 29,290; (1885) 31,669. Coblenz (Fr. *Coblence*) was known to the Romans as *Confluentes*. From 1018 till 1796 it belonged to

Trèves. In 1798 it was made the capital of the new French department, Rhine and Moselle, and by the treaty of 1815 was given to Prussia.

Cob-nut, a name given to some of the largest and finest cultivated varieties of the Hazel-nut (q.v.).—In the West Indies the name cob-nut is given to the fruit of *Onphalea triandra*, a tree of the natural order Euphorbiaceæ. It is also called Hog-nut. The tree has a white juice, which turns black in drying, and in Guiana is used instead of ink. The albumen of the seed is eaten, after the embryo, which contains a cathartic principle, is removed.

Cobourg, a port of entry and capital of North-umberland county, Ontario, on Lake Ontario, 69 miles NE. of Toronto. It is a railway junction, and contains a Wesleyan university, and several woollen-mills, foundries, and breweries. Pop. 4442.

Cobra da Capello ('hooded snake'), the Portuguese name for one of the most deadly of the poisonous Indian snakes, technically known as *Naja tripudians*. It belongs to the sub-order of venomous Colubrine snakes (Proteroglyphia), in which the fangs borne on the upper jaw are not perforated by a complete canal, but possess simply an anterior groove down which the poison trickles. The cobra is a large snake, 5 feet or more in length; the

Head of Cobra.

colour varies considerably from pale yellow to dark olive; one variety has spectacle-like black markings on its neck. By the dilatation of the anterior ribs during excitement the neck can be distended so as to produce a hood-like appearance. It is by preference nocturnal, and feeds on amphibians, reptiles, birds, eggs, small mammals, &c. It does not appear to be naturally aggressive, but instinctively assumes a threatening attitude when disturbed. It then dilates its neck, hisses loudly, and prepares to strike by raising its fangs in the usual snake fashion. The habits vary greatly in different situations. It may haunt human dwellings for the sake of poultry and other food, and is said to occur 8000 feet up the Himalayas. Though essentially land animals and fond of concealing themselves among old masonry, stone heaps and the like, the cobras can swim and climb with ease. In gracefulness of movement they excel. The head and neck are often raised above the level of the rest of the body, which remains horizontal. In spite of pictures to the contrary, they can only raise the front part of the body to a very limited extent.

The bite of the cobra is as usual accompanied by the compression of one of the salivary glands modified as a poison bag. The secretion trickles down the grooves of the fangs, and entering the wound produces rapid nervous paralysis, from which recovery is, to say the least, extremely rare. Great numbers of deaths occur annually in India from cobra bites, but as the assailant often escapes, identification is frequently a matter of conjecture. No certain remedy is known, but excision, cauterising, ligaturing, doses of ammonia, drugging with rum, &c. are often resorted to. The victims are usually natives, who, going about after dark, not unfrequently trample upon the cobra and other snakes. The rattles which they use to warn off the reptiles do not appear to have much more effect

than the spells to which they trust. The cobra has become the centre of numerous native superstitions, the object of animal-worship, and a favourite subject with the adroit snake-charmers.

Naja tripudians is found in India, Java, and South China; *N. haje*, an allied species, is common in Egypt and parts of Africa. The coral snake (Elaps), the rock-snake (Bungarus), the venomous water-snake (Hydrophis), are genera within the same sub-order. See SERPENT; also Professor G. Günther's *Reptiles of British India* (Ray Society, 1861), and Sir Joseph Fayrer's *Thanatophidia of India* (1874).

Coburg, the capital of the duchy of Coburg, in the united duchy of Saxe-Coburg-Gotha, is picturesquely situated on the left bank of the Itz, 81 miles SSE. of Eisenach by rail. The older part of the town, which is fairly well built, is surrounded by attractive modern suburbs. Coburg is, alternately with Gotha, the ducal residence, and the palace, erected in 1549, is one of the principal buildings in the town. Among the others are the government buildings, the arsenal, containing a public library, the town-house, and the palace of the Duke of Edinburgh. The old castle of Coburg, mentioned in 1057, beside which Coburg originally grew up, is situated on an eminence 530 feet above the town. It afforded Luther a shelter during the Diet of Augsburg in 1530, and in 1632 successfully resisted a siege by Wallenstein. In 1782 it was converted into a prison, but in 1838 it was thoroughly restored, and now contains valuable collections of engravings, zoology, &c. Luther's apartments are preserved as he used them. Coburg has manufactures of woollen, cotton, marquetry, baskets, porcelain, furniture, and carriages, and exports beer. Pop. (1875) 14,567; (1885) 16,210. Prince Albert, to whom a statue was erected in the market-place of Coburg by Queen Victoria in 1865, was born at Rosenau, a ducal seat 4 miles to the north.

Coburg Peninsula, the most northerly part of Australia to the west of the Gulf of Carpentaria, runs out in a north-west direction towards Melville Island, from which it is divided by Dundas Strait. On its north side is the bay known as Port Essington, at the head of which was established, in 1831, the settlement of Port Victoria—abandoned, on account of its insalubrity, in 1850. Swamp buffaloes, originally brought from Java, have increased here enormously.

Cobweb. See SPIDER.

Coca (*Erythroxylon Coca*—which has of course no connection with Cocoa or with Cocoa-nuts), a shrub of the order Erythroxylaceæ, of which the leaves furnish an important narcotic and stimulant. The shrub is 6 or 8 feet high, and somewhat resembles a blackthorn bush; the leaves are ovate-lanceolate, simple, and with entire and slightly waved margins, and strongly marked veins, of which two on each side of the midrib run parallel to the margin. It has been in use from a very remote period among the Indians of South America, and was extensively cultivated before the Spanish conquest. Many of the Indians of the Peruvian Andes are to this day excessively addicted to it, and its use is quite general among them, besides extending to men of European race. The dried leaves are chewed with a little finely powdered unslaked lime, or with the alkaline ashes of the Quinoa (q.v.), or certain other plants. An infusion is also occasionally used. An habitual coca-chewer takes a dose about four times daily. In soothing effect it recalls tobacco, but its influence is a much more remarkable one. It greatly lessens the desire for ordinary food, and at the same time permits of much more sustained exer-

tion, even without sleep; it affects the nervous mechanism of respiration, so that the difficulty of breathing, so common in the ascent of long and steep slopes at high elevations, is little felt. These properties readily explain its high esteem among

Coca (*Erythroxylon Coca*):
a, a flower; b, fruit.

the Indians, to whom long and difficult journeys, heavy burdens, and constant privation have always been familiar.

COCAINE.—In Europe, little importance was attached to coca until the veteran pharmacologist Christison awakened interest by personally verifying in old age its sustaining powers. Investigations followed, and the alkaloid *cocaine*, upon which the active properties mainly depend, has now come into regular use as a local anæsthetic, by help of which not merely some of the operations of dentistry, but much more serious surgical operations, can be performed without chloroform. To oculists it is of special value, at once dilating the pupil and removing all sensibility. Cases of intoxication and abuse are not infrequent with the leaves, and have been already recorded in connection with the more powerful extract.

Cocana'da, a seaport and headquarters of Godavari district, Madras, 315 miles N. of Madras. Its roadstead is comparatively safe, and it exports cotton, oil-seeds, sugar, rice, and cigars. Pop. (1881) 28,856.

Cocceius, or KOCH, JOHANNES, a distinguished theologian, was born at Bremen in 1603, and studied at Hamburg and Franeker. In 1636 he became professor of Hebrew there, and in 1650 of Theology at Leyden, where he died in 1669. His chief work is the *Lexicon et Commentarius Sermonis Hebraici et Chaldaici Veteris Testamenti* (Leyden, 1669), the first tolerably complete dictionary of the Hebrew language. Cocceius held very peculiar hermeneutical principles, which enabled him to discover the whole New Testament in the Old. The representation abundantly employed in the former of a covenant between God and man, usurped the place of the New Testament doctrine of the Fatherhood and Sonship; and Cocceius carried the 'covenant theology,' as it is called, to an absurd extreme (see COVENANT). The most complete exposition of his views is in his *Summa Doctrinæ de Fœdere et Testamento Dei* (1648).

Cocceji, HEINRICH FREIHERR VON, born at Bremen, March 25, 1644, studied jurisprudence and philosophy in Leyden from 1667 to 1670, and

went from thence to England. In 1672 he was made professor of Law at Heidelberg; in 1689, at Utrecht; and in 1690, at Frankfort-on-the-Oder. In 1713 the emperor named him a baron of the realm. Cocceji died in 1719. His work on civil law (*Juris Publici Prudentia*, 1695) was long used as a text-book.—His youngest son, SAMUEL, born at Heidelberg in 1679, acquired no less renown. He too, in 1703, became professor at Frankfort-on-the-Oder, filled several honourable state-offices, and was ultimately the chancellor of Frederick the Great. He died in 1755. He reformed the Prussian administration of justice, and published several works on law.

Coccinella. See LADY-BIRD.

Cocco, Coco Root, or EDDOES, plants of the genus *Colocasia*, and of the nearly allied genus *Caladium*, of the order Araceæ, widely cultivated in tropical and subtropical countries for their edible starchy root-stocks, of which the food-value broadly corresponds to the potato. These are deprived by roasting or boiling of the characteristic acidity of the order, which, indeed, some of them possess in a comparatively small degree. They are sometimes included under the name *Yam*, but are totally different from the true *Yam* (q.v.). The names more strictly belong to *Colocasia antiquorum*, a stemless plant with ovate leaves, and flowers inclosed in a cylindrical erect spathe. This is a native of India, but was early introduced to Egypt and the Mediterranean countries, whence it has now passed even to America. *C. esculenta*, *C. macrorrhiza*, or *Taro* (q.v.), and *C. Himalensis* are also of economic importance in different parts of the world, and many species of these and allied genera are to be seen in European hothouses, where their handsome foliage has gained them an important place.

Coccoliths are small saucer-like discs found abundantly in the Atlantic ooze, probably unicellular algae. They are sometimes called *coccolite*, a word also used to denote a greenish kind of Angite (q.v.).

Coccoloba. See SEASIDE GRAPE.

Coccomilla, or CUCUMIGLIA (*Prunus coccomilla*), a species of plum, a native of Calabria, and of which the bark—particularly of the root—is used in that country for the cure of intermittent fevers.

Coccos'teus, a genus of fossil placogonoid fishes, pertaining chiefly to the Devonian and Old Red Sandstone system, but met with also in Silurian strata. The head was protected by a great shield covered with tubercles. Besides this bony cuirass there was also a ventral shield, but the rest of the body was naked. The mouth was furnished with small teeth.

Cocculus Indicus (Ital. *coccola*, 'a berry') is the fruit of the *Anomirta paniculata*, a climbing shrub found in the eastern parts of India, and in the Malayan Archipelago. It was introduced into Britain in the 16th century for the purpose of stupefying fish so that they might be caught by hand. It acts as an acrid narcotic poison, and when the berries are thrown into a stream it quickly poisons any fish in the neighbourhood. It contains a crystalline principle called picrotoxine, which is very poisonous. It has often been asserted that as *cocculus indicus* imparts to beer a bitter taste, and at the same time a fullness and apparent richness, it is largely used in the manufacture of that beverage. As its effects are very deleterious, considerable attention was directed to the point, but no evidence is as yet forthcoming to substantiate the statement. In 1876 the report of the Laboratory Department of the Inland Revenue stated that in no case were

the officers of the department able to detect it either on the brewer's premises or in the beer itself. Of the large quantity imported into England, nearly the whole is re-exported to the Continent.

Cocculus Indicus :

a, branch with leaves; b, panicle of female inflorescence; c, a female flower; d, the same with sepals removed; e, male flower; f, fruit. (From Bently & Trimen.)

In Russia and elsewhere it is a popular remedy for tapeworm, lice, &c.; but when applied to the scalp it is not unattended with danger, as several deaths have occurred from its use.

Coccus, a genus of insects in the order Hemiptera, and type of a family (Coccidae), including many forms very injurious to plants, and a few others which have come to be of use to man. For the latter, see COCHINEAL, LAC, MANNA, WAX. As general characteristics may be noted the beaded feelers, the general absence of wings in the female, the degeneration of suctorial proboscis and posterior wings in the males, and the peculiar history of both sexes. The young forms are somewhat tortoise-like, and run about on plants with some activity. The adult females attach themselves by their proboscis to a juicy part of the plant, and surrender themselves to feeding and maternity. They often become berry-like, plump, much resembling excrescences, or else very flat and scale-like. In the latter form they are often called scale-insects. The body always degenerates more or less, and after fertilisation becomes simply a case, or eventually a dead covering for the eggs and larvæ. The young males also come to rest, and undergo a peculiar metamorphosis. From the resting larva an elegant male insect results, with developed anterior, but degenerate or aborted posterior wings. The males fertilise the females, but being without suctorial proboscis, are probably short-lived. In fact, both male and female adults seem to fall victims to the characteristics of their sex. The young shelter for a while under the dead female, and then start for themselves. For the important species and related genera, see the articles above referred to.

Coccyx. See VERTEBRAL COLUMN.

Coccyzus. See CUCKOO.

Cochabamba, a central department of Bolivia, with offshoots of the Eastern Cordilleras, and extensive plateaus. The climate is equable and healthy, and though the department is comparatively poor in metals, its fertile valleys render it the richest as well as the most picturesque district of the republic. Agriculture and cattle-raising are the chief occupations; but here, as elsewhere in Bolivia,

trade is sadly hampered by the want of roads. Area, 26,685 sq. m.; the population was in 1861, 352,392. The capital, Cochabamba (8396 feet above the sea), on a tributary of the Guapay, was founded in 1565, as Ciudad de Oropesa. It has some fifteen churches, a so-called university and high school, and an industrious population, variously estimated at from 15,000 to 40,000, with a trade in corn and Peruvian bark.

Cochin, a native state of India, politically connected with Madras, between the British district of Malabar and the state of Travancore, with the Arabian Sea on the SW. It contains 1361 sq. m., and (1881) 600,278 inhabitants. Its hydrography is singular. The Western Ghats, which have here an elevation of fully 4000 feet, intercept the south-west monsoon, and render the coast one of the most humid regions in the world during June, July, August, and September. As the space between the mountains and the sea is almost on a level with the tide, the countless streams have each two contrasted sections—a plunging torrent and a sluggish river ending in a brackish estuary. Further, these estuaries, almost continuously breasted by a narrow belt of higher ground, form between them a backwater or lagoon of 120 miles in length, and of every width between a few hundred yards and 10 miles, which communicates at only three points with the ocean. The forests produce the cocoa-nut, teak, red cedar, and many other woods, while the low country produces drugs, dyes, and gums. The great mass of the population (430,000) are Hindus, but there are also 34,000 Mohammedans and 138,000 Christians (of the Syrian and Roman confessions), and 1250 Jews. The capital is Ernakolam (pop. 14,000). Cochin formed a treaty with the East India Company in 1798.

Cochin, once the capital of the principality above described, but now a seaport of the district of Malabar, in the presidency of Madras, stands on the south side of the principal channel between the open ocean and the backwater mentioned in the preceding article. In spite of the bar, Cochin is next to Bombay on this coast for shipbuilding and maritime commerce, the annual exports reaching a value of £700,000. Here the Portuguese erected their first fort in India in 1503. They were supplanted by the Dutch in 1663; and in 1796 Cochin was captured by the British. Pop. (1881) 15,698, of whom 8360 were Christians, 4383 Hindus, and 2942 Mohammedans. Half a mile south is a town of the same name, in the native state of Cochin (pop. 13,775).

Cochin-China is a usual name for Annam (q.v.), but is specifically used also for French Cochin-China or Indo-China, a colonial possession of France, occupying the south extremity of the Indo-China peninsula, from 8° to 11° 30' N. lat., and from 104° 26' to 107° 30' E. long., bounded N. by Cambodia and Annam; area, 23,400 sq. m. Through nearly its whole extent Cochin-China is low and almost flat. To the north and east, however, the ground rises into the hills of Cape St Jacques, Ba-ria, and Bien-hoa, and the mountain of Dienba. Cochin-China is watered in the west by two branches of the Mekhong (q.v.), the Han-giang and the Tien-giang, which follow a nearly parallel course for about 120 miles. In the east the Dong-nai River flows from north-east to south-west, receiving the Saigon River from the north-west. The Little Vaico flows parallel to and south of the Saigon River. These rivers are all connected with one another by the innumerable *arroyos* and canals which intersect Cochin-China in all directions. The climate alternates between the rainy season,

from April to October, when it rains almost every day, and the dry, from October to April, when no rain falls. The temperature rises in the dry season to 95° F. by day and 62° by night, and in the wet season varies between 68° and 86°. Of all hot climates that of Cochinchina shows perhaps the least considerable variations. The climate is trying, but its insalubrity has been much exaggerated. The soil, mostly alluvial, is exceedingly fertile, producing the best rice in the world. Sugar-cane, tobacco, cotton, arachis, mulberry, indigo, maize, tea, betel, hemp, are raised on a small scale; and coffee, cacao, and vanilla have also been introduced. The province of Bien-hoa and the north of Saigon do not yield to the finest lands of India in the luxuriance of their vegetation and the beauty and variety of their fauna. The province of Vinhlong owes its Annamite name of *vuông* ('garden') to the abundance, variety, and exquisite taste of its fruits.

The population in 1885 amounted to 1,792,933. Of these, 2022 are Europeans, 1,500,000 Annamites, 105,463 Cambodjans, 8000 savages (Moi, Chams, &c.), 50,526 Chinese, 3373 Malays. The total exports of rice in 1887 amounted to the value of £1,610,813. The number of vessels clearing out of Saigon in 1887, exclusive of the mail-boats, was 374, of 438,719 tons, over a half of the entire tonnage being British. A railway of 44 miles between Saigon and Mytho has been in operation since 1885, while Saigon and Cholon are also united by a steam-tramway. In 1885 the lines of telegraph wire in Cochinchina measured 1366 miles; and Cape St Jacques is joined by telegraph to Singapore, Fankin, and Hong-kong. Though not yet paying its expenses, the colony of Cochinchina has improved financially, and with the development of its resources its ultimate profit to France is considered assured. For an account of the natives and history, see ANNAM; for a map, BURMA; and for fowl, POULTRY.

Cochineal, a dyestuff employed in dyeing scarlet and crimson, and in the preparation of the pigments Carmine and Lake (q.v.).

Cochineal consists simply of the bodies of the females of a species of *Coccus* (q.v.), called *C. cacti*, because it feeds upon plants of the Cactus family,

Cochineal (*Coccus cacti*):
a, living on cactus (*Opuntia*); b, male; c, female.

particularly on one, therefore designated the cochineal plant, but known in Mexico as the Nopal (*Opuntia coccinifera*), figured in the article

CACTEÆ. This plant is nearly allied to the prickly pear, and assumes a somewhat tree-like form. The insect as well as the cactus are natives of Mexico and other warm parts of America, but they are now cultivated chiefly in Guatemala. This cultivation was carried on by the Mexicans long before the country was known to Europeans. The insect is not uncommon on wild cacti in Texas and Florida. Both plant and insect have been successfully introduced into the Canary Islands, Algeria, Java, and Australia. But the attempt to produce cochineal in India has been practically a failure.

The cochineal insect is a small creature, a pound of cochineal being calculated to contain 70,000 in a dried state. The male is of a deep-red colour, and has white wings. The female, which is wingless, is of a deep-brown colour, covered with a white waxy powder; flat beneath, convex above.

In some parts of Guatemala large plantations of Nopal exist for the cultivation of the *C. cacti*. Before the rainy season commences, branches of this cactus plant covered with these insects are cut off and stored in buildings to protect them from the weather. When the wet season is over, four or five months afterwards (October), the plantations are again stocked from these supplies. Little 'nests' of some vegetable fibre, each containing about a dozen females, are placed on the spines of the cacti. The eggs are soon deposited, and when the young females are developed, they spread over the plants, attaching themselves to the leaves, and looking more like vegetable excrescences than insects. They become covered with a cottony substance. The first crop of pregnant females, only these being valuable for cochineal, is gathered in December, and several more crops are obtained till the following May.

In the Canary Islands the insects are reared in winter and put out on the cactus leaves from May to July. Small gauze bags containing pregnant females are hung on the cactus plants, from which the young when developed spread over the leaves. In August and September, just before the females are ready to deposit their eggs, they are collected in trays, and those gathered in one day are placed in the evening in an oven heated to 150° F. They are afterwards more thoroughly dried in the sun. Hot iron and boiling water are also used in killing the insects. According to the way the insect is killed and dried, the cochineal is known in commerce as silver or black; an inferior kind being sometimes called foxy. The colouring principle of cochineal is called cochinealin or carminic acid, and the insects scarcely yield more than 10 per cent. of pure dye, although the amount is generally supposed to be much greater. Carmine has also been demonstrated in other kinds of coccus and in aphides.

The cochineal industry has suffered very much through the introduction of aniline dyes. To see to what extent this is the case, it need only be stated that the amount of cochineal exported from the Canary Islands, where it is produced in by far the largest quantity, amounted in 1869 to 6,310,600 lb., which was valued at £842,921, while in 1886 the total export from these islands only reached 1,440,968 lb., valued at £78,521. The price of it fell between 1880 and 1888 from two shillings to about one shilling per lb.

Cochlæaria. See SCURVY GRASS.

Cochrane, LORD. See DUNDONALD.

Cockade (Fr. *coquarde*, or *coquarde*), an ornament or knot of ribbon or rosette of leather, worn either as a military or naval decoration, or as the badge of a political party. Cockades made of ribbons of the national colours were worn by

soldiers during the wars of the 18th century, the white and red being united in the combined army of France and Spain. In 1767 an authoritative regulation was issued that every French soldier should wear a cockade of white stuff; and in 1782 cockades were prohibited to all but soldiers. From this time till the Revolution the cockade was an exclusively military badge; and, both in France and England, 'to mount the cockade' was synonymous with becoming a soldier. After the Revolution, the tricolor ribbon took the place of the white cockade.

In England, after the expulsion of the Stuart family, the white cockade became the distinctive mark of the adherents of the exiled house, in opposition to the orange of Nassau and the black of Hanover; it is a favourite theme in Jacobite songs. The black cockade, to be seen on the hats of officers' servants, was unknown in Britain till the accession of the House of Hanover, and was then introduced by George I. from his German dominions. It seems to be understood that the right to use it belongs not only to naval and military officers, but also to the holders of some offices of dignity under the crown, including privy-councillors, officers of state, supreme judges, &c., and some would extend it to deputy-lieutenants. The privilege is one of which the law takes no cognisance. See **BADGE**.

Cockatoo, a popular name for several genera and species of parrots (Psittaci), which may be associated in a family of Cacatuidæ or Plissolophinae. Some of them are well known as decorative birds. The general characteristics are the tuft on the head, the strong high beak with a notch behind the point, the frequently bright colours of the plumage, the long wings, the loquacious habit. The cockatoos inhabit Australia, Tasmania, New Guinea, and the Indian Archipelago. The word which the birds seem to say, and which is curiously represented by the English *cockatoo*, is said to be Malayan for 'old father,' and to have been taught to the birds by their captors. Of the genus *Plissolophus*, fifteen Australian and Malayan species are known—e.g. *Pl. sanguineus*, *Pl. molluccensis*, *Pl. cristatus*. The great palm cockatoo (*Microglossus aterrimus*) is the strongest of the parrot tribe, and measures about two feet in length; its colour is mostly black; its special home is New Guinea. The crestless Nasiterna, the smallest of all the parrots, also inhabits New Guinea. The black cockatoos (*Calyptorhynchus*) form another important genus in Australia. The cockatoos feed mainly on fruits and seeds, but do not disdain insect larvæ.

Cockatrice, a fabulous monster, often confounded with the Basilisk (q.v.), and regarded as possessing similar deadly powers. To the charms of the basilisk it added a dragon's tail, armed with a sting; and it shared also its power of destroying by a glance, so often referred to in Shakespeare and other early writers. In medieval art the cockatrice is an emblem of sin generally, and the special attribute of St Vitus. The name occurs in the English authorised version of the Old Testament, where the original Hebrew word means evidently a winged monster having the head, body, and feet of a cock, the tongue barbed, and the tail of a dragon.

Cockayne. See **COCKNEY**.

Cockburn, SIR ALEXANDER, judge, was born 24th December 1802, studied at Cambridge, was called to the bar in 1829, and soon became distinguished as a pleader before parliamentary com-

mittees. In 1847 he became member of parliament for Southampton in the Liberal interest, became Solicitor-general and was knighted in 1850, was made Chief-justice of the Common Pleas in 1856, and Lord Chief-justice in 1859. He was prosecutor in the Palmer case; and among the many famous trials over which he presided were the Wainwright case and Tichborne case. He represented Britain at the Geneva arbitration in the Alabama case. He died 20th November 1880.

Cockburn, ALISON, poetess, was born 8th October 1713, the daughter of Robert Rutherford, laird of Fairnilee, Selkirkshire. In 1731 she married Patrick Cockburn, advocate, and in 1753 was left a widow, with an only son, who predeceased her in 1780. She died 23d January 1795, having for sixty years and more been a queen of Edinburgh society: in person she was not unlike Queen Elizabeth. Of her lyrics the best known is the exquisite version of *The Flowers of the Forest* ('I've seen the smiling of Fortune beguiling'), commemorating a wave of calamity that swept over Ettrick Forest, and first printed in 1765. Mrs Cockburn in 1777 discerned in Walter Scott 'the most extraordinary genius of a boy'; in 1786 she made Burns's acquaintance. See *Songstresses of Scotland* (vol. i. 1871), and Craig-Brown's *History of Selkirkshire* (1886).

Cockburn, HENRY, Scottish judge, was born 26th October 1779, perhaps at Cockpen, but more probably in the Parliament Close of old Edinburgh. He entered the High School in 1787, and the university in 1793, 'being kept,' in his own words, 'nine years at two dead languages which we did not learn.' Dugald Stewart's lectures, then, 'were like the opening of the heavens,' they 'changed one's whole nature'; and through a debating club he became the companion of Jeffrey, Horner, and Brongham, from whom he imbibed Whig opinions, greatly to the annoyance of the hereditary Toryism of his family. He was called to the Scottish bar in 1800; and in 1807 his uncle, the all-powerful Lord Melville, gave him an advocate-deputeship—a non-political post, from which, on political grounds, he 'had the honour of being dismissed' in 1810. He rose, however, to share with Jeffrey the leadership of the bar, and with Jeffrey was counsel for three prisoners accused of sedition (1817-19). His powers were better adapted for success with a popular than with a professional tribunal. Simple, clear, and impressive, at times pathetic, humorous at times, and, when he pleased, eloquent, but always unaffected, always Scotch, he would urge his case with an earnestness and candour that was all but irresistible. A zealous supporter by pen as well as by tongue of parliamentary reform, he became Solicitor-general for Scotland under the Grey ministry in 1830; had the chief hand in drafting the Scottish Reform Bill; was elected Lord Rector of Glasgow University (1831); in 1834 was made, as Lord Cockburn, a judge of the Court of Session; and three years later a lord of justiciary. He died, 26th April 1854, at Bonally Tower, his beautiful home by the base of the Pentlands since his marriage in 1811, and was buried near Jeffrey in the Dean Cemetery, Edinburgh.

Besides five or six pamphlets, and as many articles in the *Edinburgh Review*, dealing mostly with legal and parliamentary reform, Cockburn was author of an admirable *Life of Jeffrey* (1852), and of four posthumous works—*Memorials of his Time* (1856), *Journal, 1831-44* (2 vols. 1874), *Circuit Journeys* (1888), and *Examination of Trials for Sedition in Scotland* (2 vols. 1888). The first three of these form a kind of autobiography, into which are woven characteristic anecdotes of old-world Scottish life, and graphic sketches of the men who composed the brilliant

Cockatrice:
in Heraldry.

circle of Edinburgh society in the first four decades of the 19th century. Withal they illustrate his love of nature and veneration for antiquity.

Cockchafer (*Melolontha vulgaris*), a common beetle of the Lamellicorn section, too well known in Europe for its voracious destruction of both crops and foliage. It is a comparatively large beetle, about an inch in length; generally of a reddish-brown colour; with fine hairs, scanty on the wing covers, but thick on the breast; and with the expanded ends of its feelers divided in the leaflet-like manner characteristic of Lamellicorns. In Scotland they are less abundant than in England.

The males appear first, usually in the month of May, and are soon joined by their partners. They fly with a whirring noise, and being hungry as well as active, do great damage to many of our common trees. After some weeks of flight, the females heavy with eggs deposit these in the ground and thereafter die. In a month or so the larvæ develop, but do not attain winged life for

Cockchafer (*Melolontha vulgaris*):
a, full-grown larva; b, pupa; c, perfect insect.

four years. Meanwhile they are anything but idle, are in fact most voracious, and do great damage to crops and herbage. In some years when the conditions are unhappily favourable, they commit ravages estimated in millions. In the fourth year of larval life the young beetles bury themselves, and fall for two months into the usual quiescence of the pupa stage. The liberated insect works its way to the surface, and takes its flight in the spring of the fifth year. In warm seasons and regions the period of larval life may be shortened. The adults do most of their disastrous work in the twilight. The only riddance seems to be the exposure of the larvæ by harrowing, and the destruction of young and old by every possible means. Rooks and other birds, insectivorous animals, and other beetles help to reduce their numbers. They have oftener been plagues on the Continent than in Britain, but in 1574 their corpses are said to have clogged mill-wheels on the Severn, and in 1688 they clung like swarming bees on the trees and hedges in Galway. *Melolontha hippocastani* is another very destructive European species. The May bug of the United States (*Lechnosterna quercina*) is an allied form of similar habits.

Cocker. See SPANIEL.

Cocker, EDWARD, schoolmaster and author, was born in 1631, and died in London in 1675. His book on arithmetic was the first English work of the kind really adapted to commercial life, and became so widely known that the

name of Cocker is as indissolubly associated with accuracy in figures as that of Murray with the rules of grammar. He attained considerable success as a teacher of arithmetic and writing in London, and is mentioned repeatedly in Pepys's *Diary*, who qualifies him as 'very ingenious and well read in all our English poets.' Cocker published over thirty works on writing or arithmetic, but the famous book so often reprinted, *Cocker's Arithmetick*, was posthumous, being dated 1678, and edited by John Hawkins. De Morgan has contended, apparently on insufficient grounds, that this book, which passed through 112 editions, was not really Cocker's work at all. Among other works published under his name are an English dictionary, and the *Muses' Spring Garden*, which contains some quaint verses of his own composition.

Cockerill, JOHN, manufacturer, born in Lancashire in 1790, was the son of William Cockerill (1759-1832), an inventor and machinist who in 1807 settled at Liège in Belgium. John, with an elder brother, succeeded to their father's business in 1812, established a woollen factory in Berlin in 1815, and in 1817 founded the famous works at Seraing (q.v.). He died at Warsaw, 19th June 1840; in 1867 his remains were brought to Seraing, where his statue was erected in 1871.

Cockermouth, a town of Cumberland, 25 miles SW. of Carlisle, and 12 NW. of Keswick. It is pleasantly situated in an agricultural district, and has a walk a mile long beside the Derwent. A ruined castle, founded towards the close of the 11th century, crowns a bold height on the left bank of the Cocker, near its influx to the Derwent. It became Mary Stuart's prison in 1568, and in 1648 was dismantled by the parliamentarians. Near Cockermouth is a tumulus, Toot's Hill; and at Pap Castle are remains of a Roman camp. Wordsworth was born here in an old-fashioned house, still standing. Pop. (1881) 6354. Till 1867 Cockermouth returned two members to parliament; till 1885 (when it was incorporated in the county), one.

Cock-fighting was common among both the Greeks and the Romans, as to-day it is common in India, the Malay countries, and Spanish America. In England it flourished for fully six centuries, the cockpit at Whitehall having been erected and patronised by royalty. In 1709 a German visitor to London describes the Gray's Inn cockpit as 'round like a tower, and inside just like a *theatrum anatomicum*, the benches rising all round;' with the scene at a cock-fight Hogarth has made us familiar. Cock-fighting was prohibited in 1365, in 1654, and in 1849; but it is still sometimes practised in spite of prohibition. Newspaper readers are familiar with paragraphs on cock-fights interrupted by the police, and fines are from time to time inflicted.

The favourite breed of fighting-cocks is the game-fowl (see POULTRY), and very large sums have been given for chicks. Much art is displayed in the training of cocks, and in trimming and preparing the cock for the combat; the fastening on of the spurs is a matter of considerable experience. Young cocks are called stags; two years is the best age. In fighting a match, a certain number of cocks to be shown on either side is agreed upon, and the day before the match the cocks are shown, weighed with the greatest nicety, and matched according to their weights. Their marks are all also carefully set down to prevent trickery. The cocks within an ounce of each other in weight are said to 'fall in,' and are matched. Those which do not fall in are matched to fight what are called 'byes.' Those which do

fall in come into the *main*. The *main* is fought for a stake upon each battle, and so much for the *main*, or the winner of the most battles in the *main*; while the byes have nothing to do with the *main*, and are usually fought for smaller sums. A middling size is considered the best, and from 3 lb. 6 oz. to 4 lb. 8 oz. is the medium. Cocks sometimes fight in silver spurs, but more often in steel. In a Welsh *main* the cocks fight until only one is left alive. By the Act of 1849, a penalty of £5 may be levied on any person keeping fighting-cocks, letting a cockpit, or otherwise connecting himself with cock-fighting, for every day that he shall so act.

Strange to say, cock-fighting was a specially sanctioned annual sport of public schools, the schoolmaster receiving a regular tax from the boys on the occasion, which was on Shrove Tuesday. It was so in the days of Henry II.; and in his *Schoolmaster* (1570) Roger Ascham announced his intention, never fulfilled, of writing a 'Book of the Cock-pitte,' as 'a kinde of pastime fitte for a gentleman.' As late as 1790 the income of the schoolmaster of Applecross in Ross-shire was formally said to be composed of salary, fees, and *cock-fight dues*. And Hugh Miller, in *My Schools and Schoolmasters*, gives an account of the yearly cock-fights in the grammar-school of Cromarty about 1812. The yet more barbarous custom of throwing sticks at cocks fastened to stakes, was also long practised at Shrove-tide. The slang *cock-shy* is a survival.

Cockie-leekie is in Scotland a kind of soup made of a fowl boiled with leeks.

Cock Lane Ghost. In the year 1762 London was thrown into a state of extraordinary excitement by the reported existence of a ghost in the house of one Mr Parsons, in Cock Lane, Smithfield. Strange and unaccountable noises were heard in the house, and a luminous lady, bearing a strong resemblance to one who, under the name of Mrs Kent, had once resided in the house, but who had died two years before, was said to have been seen. Dark suspicions as to Mr Kent having poisoned the lady were immediately aroused, and were confirmed by the ghost, who, on being interrogated, answered, after the fashion of the spirits of our own day, by knocking. Crowds were attracted to the house to hear the ghost, and the great majority became believers. At length a plan was formed by a few sceptics to ascertain the real origin of the noises. Parson's daughter, a girl eleven years of age, from whom they supposed the sounds to proceed, was taken to another house by herself, and threatened with the imprisonment of her father in Newgate if she did not renew the rappings that evening, the noises having for some time been discontinued. She was discovered to have taken a board with her into bed, and when the noises took place, no doubt was entertained that they had all along been produced by similar methods. A prosecution was then raised by Mr Kent, and Parsons was condemned to stand thrice on the pillory for imposture and defamation. Among those who visited the house was Dr Johnson, but it is not true that, with all his natural bent to easy belief in the supernatural, he was one of the dupes of this miserable imposture. Churchill's gross caricature of Pomposo's credulity in his tiresome poem of over four thousand lines, *The Ghost*, was mere false and malicious slander, and deserved the same payment that the burly Johnson promised to give Foote upon his own stage if he persisted in his intention to take him off in the same way.

Cockle (*Cardium*), a large and typical genus of bivalve molluscs (Lamellibranchs). The thick,

ribbed, heart-shaped, equal-valved shell, and the large knee-bent 'foot' are characteristics well known to every one. The shell is closed by two muscles; the hinge has large teeth; there are two minute respiratory siphons. About two hundred living species are known, and have a very wide distribution, though most abundant in the tropical seas. They live freely and gregariously, generally buried in the mud or sand. The foot is used for burrowing, but by it the cockle can also jump a few inches. *C. edule* is very largely eaten, and is often sold in great quantities on the streets of British towns. The fossil forms are very numerous, and increase from the Silurian onwards. (For figure and structure, see BIVALVES.)

Cockle, or CORN-COCKLE (*Githago—Agrostemma—segetum*), of which one species, a caryophyllaceous annual weed, is common amongst crops of grain, is a native of Europe or the west of Asia, but is now found in cereal crops in almost all parts of the world. Its tall graceful habit, and large lilac-purple flowers, make it one of the most beautiful of corn-weeds; its seeds are, however, unwholesome, especially to fowls and domestic animals, and thus the undesirableness of its presence in crops is increased. A special sieve is employed for their removal in bad cases in Germany. It is an annual plant, clothed with very long hair; with large, solitary, terminal lilac flowers. The root, stem, leaves, and seed were formerly used in medicine; the seed is still sometimes sold in Germany under the name of Black Cumin (Schwartzkümmel). The corn-cockle is a very troublesome weed in some parts of Britain, and is rare and almost unknown in others.

Cockney, a familiar name for a Londoner, the earlier meaning of which was a foolish, effeminate person, or a spoilt child. The original meaning is very obscure, but in Chaucer *cokeney* (a trisyllabic word) had much the same meaning as this. Professor Skeat points out its obscurity of meaning in two famous passages in *Piers Plouman* (x. 207), and in the last stanza of the 'Tournament of Tottenham' in Percy's *Reliques*. The word occurs twice in Shakespeare (*Twelfth Night*, IV. i. 15; and *Lear*, II. iv. 123), and there with the meaning, according to Schmidt, of a person who knows only the life and manners of the town, and is consequently well acquainted with affected phrases, but a stranger to what every child else knows. The French *Pays de Cocagne*, with which the word is usually connected, denotes a Utopia—an imaginary land of luxurious abundance without labour. The true origin of the word *cockney* is extremely obscure. The best explanation offered seems to be that of Wedgwood, approved by Skeat in his 'Errata and Addenda,' which connects it with the French *coquin*, 'a rogue'; itself, according to Littré and Scheler, derived through a Low Latin *coquinus* from Latin *coquus*, 'a cook' or 'kitchen-scellion.' Diez, however, notes that the word *coquin* occurs in none other of the Romance tongues, and conjectures a connection with the old Norse *kok*, 'the throat.' The Welsh and Gaelic words that have been supposed by some to be cognate with *cockney* may safely be disregarded.

Cock of the Plains. See GROUSE.

Cock of the Rock (*Rupicola*), a genus of South American Passerine birds in the family of Cotingidæ or Chatterers, beside the Cotingas (q.v.) and Pompadours, the Umbrella-bird (*Cephalopterus*), and the Bell-bird (*Chasmorhynchus*). The bill is high and strong, the tail short and straight, the sole naked, the feet are strong and stout. The male is remarkable for a lofty, laterally compressed crest. In the best-known species (*R. crocea*), from Guiana and the north-east of Brazil, the male is

predominantly orange-red in colour, with a dark purple-red crest, and decidedly larger than the sober brown female. It is about the size of a common pigeon.

Cock of the Woods. See CAPERCAILLIE.

Cockpit, in a ship of war, is the name still given to the compartment in the lower part of the ship where the wounded are attended to during action. The surgery and dispensary which contains the medicine chests for the ship's company adjoin the cockpit.

Cockroach (*Blatta* or *Periplaneta*), a large genus of insects, type of a family (Blattidae) within the important order Orthoptera, which likewise includes locusts, grasshoppers, crickets, leaf-insects, earwigs, &c. Though often spoken of as beetles, cockroaches have in no sense direct connection with that order. Familiar enough as pests, cockroaches require no minute description. The antennae longer than the body—i.e. over an inch, the bent down head (half-hidden by the large first thoracic plate), the long spiny legs compressed terminally, the flat broad segmented abdomen, the cigar-shaped anal appendages (which are supposed by some to represent a pair of rudimentary abdominal legs), are among the more striking external features. The two adult sexes in the common cockroach are readily distinguished, since the female has a somewhat broader abdomen, and only slight traces of wings. In the male, the anterior wings form stiff opaque wing-covers (*tegmina*), while the posterior pair are membranous, really wing-like, and folded longitudinally; in the female, the *tegmina* are very small, and the posterior wings only suggested by marks. Certain cockroaches, however, are wingless in both sexes. There are complex copulatory and egg-laying structures in the respective sexes.

Common Cockroach :
a, female; b, male.

The essential male organs atrophy in the adult males. The eggs are surrounded by a peculiar hard capsule, which the female carries about for a long time, but eventually attaches by a glutinous secretion to some suitable sheltering object. This cocoon, in the common species, usually contains sixteen eggs, one from each of the ovarian tubes. Like other true Orthoptera, the cockroaches have no marked metamorphosis in their life-history. The larvae, when developed, appear to soften the edges of a side slit in the inclosing capsule, and emerge through this into active life. They pass through no fasting quiescent state, and when hatched, differ from the adults only in minor quantitative details. They are said to moult seven times before becoming quite adult in the fifth year of their life.

Cockroaches are voracious insects, devouring both animal and vegetable substances, which they seek out by aid of their almost certainly olfactory

antennae. Their mouth organs (three pairs of jaws) are very typical, and well adapted for biting. The juices of the mouth leave a disgusting smell on the objects over which the insects pass. They are nocturnal in habit, most abundant in warm countries, fond of sheltering in houses, and notoriously a pest to bakers and millers. To get rid of them a tame hedgehog is often employed, or they may be caught in large numbers in a slippery milk basin, baited with treacle, and led up to by a piece of wood which cannot be regained from the bottom. The commonest species in Britain (*Periplaneta orientalis*) is said to have been brought to Europe from Asia within the last two hundred years; *P. americana* has found its way hither in bales, &c. from America. The German cockroach (*Blatta* or *Phyllodromia germanica*) is a troublesome, widely distributed form, which appears, however, to go to the wall before our common pest. Another form (*Blatta* or *Ectobia lapponica*) of smaller size, which occurs commonly in the woods of north and central Europe, is specially important in Lapland, where it sometimes does great injury by devouring the winter stores of salted fish. The largest form known is a native of South America and the West Indies, which measures about 3 inches in length, and makes a loud drumming noise. The cockroach is an ancient insect, having been actually found in Silurian strata. As a tolerably evolved, and yet not too highly specialised type, the cockroach forms a very convenient type for the anatomical study of insects. See Miall and Denny, *The Cockroach: an Introduction to Entomology* (1886).

Cockscomb (*Celosia cristata*), an East-Indian annual of the order Amarantaceae, familiar in conservatories, often also planted out in warm borders, especially in the southern parts of Britain. It grows with an upright stem, which becomes flattened upwards, divides, expands, and forms a sort of wavy crest, covered with pointed bracts, and bearing on its surface many very small abortive flowers, so crowded as often to present a rich velvety appearance. The colours are various, and often very brilliant. In the wild species, however, the flowers are of ordinary type, and in simple spikes and panicles; while in the so-called *C. aurea*, a golden variety formerly much cultivated, only a few flowers of the base of the inflorescence are perfect, the other being represented only by bracts and scales; while in the cockscomb proper the monstrosity known as *Fasciation* (q.v.) has further taken place.

Cock's-foot Grass (*Dactylis*), a genus of Grasses, closely allied to Fescue (*Festuca*), but differing in habit. The Common or Rough Cock's-foot Grass (*D. glomerata*) is a native of both pale-arctic and nearctic regions, and is very abundant in Britain. It furnishes an important part of both natural and artificial pastures. In America this grass is called Orchard Grass, and is extensively cultivated. To this genus belongs also the Tussac Grass (q.v.). See PASTURE, GRAMINEÆ.

Cockton, HENRY, comic novelist, was born in London in 1807, and died 26th June 1853 at Bury St Edmunds, where eleven years earlier he had married and settled in business. Unless for their illustrations, all of his ten works are almost forgotten but one—*Valentine Vox, the Ventriloquist* (1840).

Cocoa, Cacao, or Coco. The different kinds of cocoa are prepared from the seeds of trees of the genus *Theobroma*.

The genus *Theobroma* (Gr., 'food of the gods') belongs to the natural order Byttneriaceae (q.v.), and contains a number of species, trees of moderate size, with large undivided leaves and clustered flowers, all natives of the tropical parts of America.

By far the most important species of this genus is *T. cacao*, to which the name cocoa-tree is often exclusively appropriated. It is extensively cultivated in tropical America and the West Indies, and its cultivation has been introduced into some parts of Asia and Africa. The fruit is somewhat like a cucumber in shape, is 6 or 8 inches long,

Cocoa (Theobroma cacao) :
a, branch with leaves; b, fruit (partly in section).

yellow, and red on the side next the sun; the rind is thick and warty; the pulp sweetish, and not unpleasant; the seeds numerous, compressed, and not unlike almonds, with a thin, pale, reddish-brown, fragile skin or shell, covering a dark-brown, oily, aromatic, bitter kernel. These seeds are the *cocoa beans* of commerce; when bruised so as to be reduced to small pieces, after being shelled or decorticated, they become *cocoa nibs*. The cocoa-tree produces larger seeds in cultivation than in a wild state. The tree attains its full vigour and productiveness in seven or eight years, and generally yields two principal crops in the year. When gathered, the fruit is subjected to five days' fermentation in earthen vessels or in heaps on the ground, and then, opened by the hand; or it is buried for a while in the earth till the pulp becomes rotten. The latter method is said to produce the best cocoa (*earthed cocoa* or *cacao terre*). The seeds are then roasted.

The average composition of the shelled and roasted bean is, in round numbers, about as follows. There is considerable variation in different samples.

(Hydrocarbon) Cocoa-butter.....	51
(Nitrogenous food) Gluten, albumen, &c.....	22
(Carbo-hydrates) Starch, gum, &c.....	13
Water.....	5
Mineral matter.....	3½
Indigestible woody matter (cellulose).....	3
Theobromine.....	2½

100

This expresses a very high nutritive value, as will be understood by comparing it with the following, which shows the proportion of corresponding constituents in lean beef—a beefsteak, for example:

(Hydrocarbon) Fat.....	4
(Nitrogenous food) Gelatin, albumen, &c.....	19
(Carbo-hydrates).....	1
Mineral matter.....	5
Water.....	72

100

In order to render its large amount of nutritious

matter digestible, the nut must be prepared. The best mode of preparation is by crushing and continuous grinding under rollers until the whole is reduced to an impalpable paste. This, when dried, adheres, and forms a hard cake. In this form it is now supplied to the navy and many merchant ships, and forms a most valuable beverage-food for sailors when scraped or pounded and boiled for a short time in water. The large amount of fatty matter and nitrogenous food renders it especially suitable for men exposed to cold and fatigue. It is a most valuable reserve food for travellers, so much of both heat-giving and flesh-forming nutriment being concentrated in a given bulk and weight. It is thus used by Swiss and Tyrolean mountaineers in the form of edible chocolate. For the preparation of chocolate, see CHOCOLATE.

An infusion of the broken and roasted shells, which are set aside in preparing the best qualities of chocolate, is used in Italy, Spain, and other countries as a cheap substitute for coffee, and bears the name of *miserable* ('poverty stricken'). The pulp of the fruit is eaten in the countries in which the tree grows, and a kind of spirit is obtained from it by fermentation and distillation.

Cocotina, cocoa essence, concentrated cocoa, are names given to preparations from which some of the cocoa-butter has been extracted to render the beverage more digestible. These, when honestly prepared, are excellent. Another mode of preparation consists in adding large quantities of cooked farinaceous material to the ground cocoa, mixing these when in a pasty condition, then drying and selling the mixture under various names—soluble cocoa, &c. Some of them contain but a homoeopathic proportion of actual cocoa, producing, when prepared by the addition of boiling water, merely a gruel flavoured with cocoa. Those who prefer such mixtures will find it economical to prepare their gruel or porridge themselves, and add genuine cocoa to it. The writer has done this by sprinkling a little powdered cocoa into ordinary Scotch porridge. By using whole or ground cocoa nibs, a genuine cocoa beverage may be obtained, but for this it is necessary to subject the nibs to very long boiling; a whole day is desirable. The full and peculiar flavour of the nut comes out, and much of the butter floats on top, while the cellulose and other insoluble constituents remain as sediment.

The *Theobromine* or special crystallisable alkaloid of cocoa resembles that of tea and coffee, but contains a larger proportion of nitrogen, and appears to be less stimulating in its action on the nervous system. Some regard it as highly nutritious.

In South Carolina the earth-nut is roasted and used as a spurious cocoa; and in Spain the root of the earth chestnut (*Cyperus esculenta*) is similarly used. See ADULTERATION.

Cocoa-nut is the current English form of what was till Dr Johnson's time spelt *Coco-nut*; *coco*, 'mask,' being the Portuguese name given to the nut from the resemblance of its lower part to a mask. It is the well-known fruit of a species of palm, *Cocos nucifera*, perhaps originally a native only of the Indian coasts and South Sea Islands, but now diffused over all tropical regions, generally succeeding best in sandy soils near the sea. It is always one of the first of the larger plants to establish itself in the low islands of the Pacific Ocean, so soon as there is soil enough, its nuts being widely distributed by marine currents, while the thick husk protects the embryo from injury. It has a cylindrical stem, about 1½ feet in diameter, and from 60 to 90 feet high, with many rings marking the places of former leaves, and bearing at its summit a crown of from sixteen to twenty leaves, which generally curve downwards, and are from 10

to 15 feet in length. The short racemes bear from five to fifteen or more nuts; and ten or twelve of these racemes, in different stages, may be seen at once on a tree, about eighty or one hundred nuts being its ordinary annual produce; the best trees are said to produce two hundred. The tree bears fruit in from seven to eight years from the time of planting, and continues productive for seventy or

Cocoa-nut Palm (*Cocos nucifera*):
a, portion of young spathe, with inclosed inflorescence; b, branch of spathe; c, smaller portion enlarged, showing a female flower below and male flower above; d, cocoa-nut—e, husk cut open, showing hard endocarp, at f opened to show the single seed.

eighty years, the fruit being gathered four or five times annually. This affords to the inhabitants of many tropical coasts and islands great part of their food; it is not only eaten as it comes from the tree, both ripe and unripe, being filled in a young state with a pleasant milky fluid, but it is also prepared in a variety of ways. The structure of the fruit will be understood by reference to the article PALMS.

The kernel of the cocoa-nut contains more than 70 per cent. of a fixed oil called Cocoa-nut Oil, or Cocoa-nut Butter, which, however, must not be confounded with the fixed oil of the chocolate, also known as cocoa butter. The oil is itself an important article of commerce, being much employed in Europe, particularly for the manufacture of *stearine candles*; and also of a *marine soap*, which forms a lather with sea-water. In tropical countries, and particularly in the East, it is much used as a lamp oil and as an unguent. It is also employed as an article of food, so long as it remains free from rancidity, to which, however, it is very liable. It has been recommended as a substitute for lard in the preparation of ointments, and in this connection its property of readily taking up a large quantity of water has given it a certain value. It may be used instead of cod-liver oil in consumption, for which purpose it is more palatable and less likely to cause nausea. It is obtained by pressure of the bruised kernel, or by boiling over a slow fire, and skimming off the oil as it floats on the surface. A quart, it is said, may be obtained from seven or eight cocoa-nuts. It is liquid in the ordinary temperatures of tropical countries, but in colder climates becomes a white, solid, butter-like oil. It becomes liquid about 74° (23·3° C.). It can be separated by compression in

the cold into a more liquid portion called *olein*, and a more solid part termed *cocostearin*, or *corosin*, which is of complex constitution, and contains at least six fatty acids.

The root of the cocoa-nut palm possesses narcotic properties, and is sometimes chewed instead of the areca-nut. The terminal bud (*Palm Cabbage*) is esteemed a delicacy, and trees are often cut down for the sake of it; the central part of the young stem is also succulent and eatable.—The saccharine sap (*toddy*) of this, as of some other palms, is an esteemed beverage in tropical countries, either in the state in which it is obtained from the tree, or after fermentation, which takes place in a few hours; and from the fermented sap (*palm wine*) a spirituous liquor (*arrack*) is obtained by distillation. The juice is often also in the East Indies boiled down to yield sugar (*jaggery*). A variety of arrack is also distilled from the fermented milk.

The dried leaves of the cocoa-nut palm are much used for thatch, and for many other purposes, as the making of mats, screens, baskets, &c., by plaiting the leaflets. The midribs of the leaves supply the natives of tropical coasts with oars.—The wood of the lower part of the well-grown stem is very hard, takes a beautiful polish, is employed for a great variety of purposes, and is imported into Britain for ornamental joinery, under the name of Porcupine Wood.—The fibrous tissue of the less mature stems is made into cordage. A kind of gum is also frequently obtained from the stem.—By far the most important fibrous product of the cocoa-nut tree is Coir (q.v.), the fibre of the husk of the imperfectly ripened nut. The husk of the ripened nut is used for fuel, and also, when cut across, for polishing furniture, scrubbing floors, &c.

The shell of the cocoa-nut is made into cups, goblets, ladles, &c., and is often polished or carved. Within the nut there is occasionally found a small stony substance, of a bluish-white colour, 'a sort of vegetable bezoar,' called in India *Calappa*, to which the Chinese ascribe great virtues. There are about 30 species of the genus, mostly South American, of which *C. butyracea* and *C. coronata* may be mentioned as specially important sources of oil and starch respectively.—The Double Cocoa-nut of the Seychelles Islands is the fruit of a totally different palm, *Lodoicea Seychellarum*. See COCO DE MER.

Cocoa-nut Beetle (*Batocera rubus*), a large Longicorn beetle, the larvæ of which are very destructive in cocoa-nut plantations, eating their way in all directions in the stems of the younger trees. They are destitute of feet, large and pulpy, and of repulsive aspect; but are esteemed a luxury by the coolies of the East. They resemble the *grugu worms* of South America.

Coco de Mer (also called *Sea* or *Maldiva Double Cocoa-nut*) is the fruit of the *Lodoicea Seychellarum* palm. Its double kernel has long had an extraordinary value over a large area in the East. As a sovereign antidote to poison, and long known only from specimens thrown up on the Maldiva coasts, it was supposed to grow on a submarine tree, and had other fables attached to it. The tree on which it grows is peculiar to some of the Seychelles Islands, reaches a height of 100 feet, and has very large fern-like leaves.

Cocoon, the silken sheath spun by the larvæ of many insects in passing into the pupa or resting stage. The cocoon proper is due to the secretion of special spinning glands, situated anteriorly or posteriorly, but larval hairs and foreign objects of many kinds may also be utilised. The amount of secretion, the arrangement of the threads, and the completeness of the covering vary very widely; nor is the presence of any cocoon whatever essential to the pupa stage. The most typical and perfect

cocoons are those of many moths, a familiar example being that of the silkworm. The delicacy, neatness, and labour exhibited by these last silken robes make them as marvellous as they are useful. See CATERPILLAR, CHRYSALIS, INSECT, and especially SILKWORM.

Cocos. See KEELING ISLANDS.

Cocytus, a river of Epirus, a tributary of the Acheron, supposed to be connected with the lower world. Homer makes it a branch of the Styx; Virgil makes the Acheron flow into the Cocytus.

Cod (*Gadus*), a genus of bony fishes in the soft-rayed order (Anacanthini), and type of a family (Gadidae) which includes some valuable food-fishes, such as Ling (Molva), Hake or 'Stockfish' (Merluccius), Burbot (Lota), &c. The genus *Gadus* itself is undoubtedly the most valuable. A moderately elongated body with small smooth scales, the three dorsal and two anal fins, the distinctness of the tail from the fins, the position of the pelvic limbs on the throat, the toothed vomer and toothless palatine, are among the more important distinctive features. The genus includes about a score of species, distributed in the cold and temperate seas of the northern part of the globe, and well known to be very abundant off Newfoundland, at the Lofoten Islands, and on the Dogger Bank. They seem to follow the herring shoals. As part of our food-supply, and as sources of cod-liver oil, the species of *Gadus* are of great economic importance.

Besides the cod proper (*G. morrhua*), the following species are well known: the Haddock (q.v., *G. oglinus*), the Whiting (q.v., *G. merlangus*), the Bib or Whiting-pout (*G. luscus*), the Power-cod (*G. minutus*), the Pollack (*G. pollachius*), the Coal-fish (*G. virens*).

The cod itself is too familiar an animal to demand description. It attains a length of 2 to 4 feet, and may weigh as much as 100 lb. The sensitive barbule on the chin is tolerably long. The colour varies considerably. A smaller variety (dorse) is sometimes distinguished—e.g. in the Baltic. The cod occurs between 50° and 75° N. lat. in great profusion, to a depth of 120 fathoms, but is not found nearer the equator than 40° lat. It spawns from January to May, according to the climate, and it is only at this season that numbers crowd together. The cod is very voracious, and feeds at the bottom on crustaceans, molluscs, worms, and even on small fishes. They are very prolific, and it has been calculated that the roe of a large female may contain towards 9 million eggs. The productiveness of the great banks of Newfoundland excels that of all others, but the cod-fisheries near the coasts of Sweden, Iceland, and the north of Scotland are also important. The Dutch were engaged in the cod-fishery as early as the middle of the 14th century, and the English resorted for this purpose to the coasts of Iceland about the same period. The French have also engaged largely in the cod-fishery. The fishery is always carried on by means of lines and hooks, partly by *long-lines* and partly by *hand-lines*. Whelks and the like are used for bait. One man has been known to catch from 400 to 550 fish, on the banks of Newfoundland, in ten or eleven hours; and eight men to take eighty score in a day on the Dogger Bank. Great quantities of dried cod are carried from Newfoundland to the West Indies, and are consumed also in the Roman Catholic countries of the south of Europe. The principal seat of the cod-liver oil industry, in which other species are also utilised, is on the Norwegian coast. The preserved 'sound' or swim-bladder of the cod is esteemed a delicacy. It is also used in a dried state as isinglass. See Day's *British Fishes*, and Günther's *Introduction to the Study of Fishes*.

Coda (Ital., 'a tail'), a passage at the end of a musical composition, intended to round it off and give a sense of completeness in form. In early music it consisted often of a few simple chords; but it was enlarged, by Beethoven more especially, into a feature of the greatest importance and dimensions, it being one of the most characteristic features in the form of his symphonies; and other composers have with rare exceptions followed his lead. See SYMPHONY.

Code (Lat. *codex* and *caudex*). The primary meaning of the Latin word was the trunk or stem of a tree; afterwards it came to signify more especially wooden tablets bound together, and covered with a coating of wax, which were used for writing on. After parchment and paper were substituted for wood, the name code was still retained. Cicero applies it to a bill; but it was not till still later, in the times of the emperors, that it was used to express a collection of laws.

In its modern sense the word code may be defined as a systematic statement of 'the laws of a country (either the whole law, or any special department of it) having the authority of an act of the legislature. In other words, it is the expression of the law of a country in a systematic and authoritative form. This definition distinguishes it, on the one hand, from a *digest*, which properly signifies a collection of the decisions and rules of the common law arranged on a methodical plan, and, on the other hand, from a *consolidated statute*, which is nothing more than the incorporation of all the statutes relating to a particular branch of the law into one general enactment. While the *digest* differs from a code in so far as it wants the authority of a legislative enactment, the *consolidated statute* differs from it in that it does not deal with the unwritten or common law.

Whether it is for the advantage of a community that its laws should be expressed in the form of a code, is a question which has been much discussed both in Great Britain and abroad. On the Continent it has been practically settled in the affirmative, while in Great Britain and in some of the states of America (particularly the state of New York) the controversy is still keenly maintained. Two principal objections urged by the opponents of codification may be thus summarised: (1) That it checks the natural growth of the law and hinders its free development; and (2) that, as law is progressive, there would be no finality—that it would be necessary to be constantly altering the code in order to adapt it to the new conditions of society. The answer usually made to the first of these objections is, that although law is a flexible and progressive science, it is nevertheless capable of being known as it exists at any given time, and if so it must be capable of being expressed in language. 'The law of a country,' observes Mr Dudley Field, the distinguished American jurist, 'may be likened to its language, and to make a code of the one is like making a dictionary of the other.' If the law is not expressed in language, it must almost necessarily be left to the fluctuating opinions of judges to say whether a particular set of facts is in any given case of legal effect or not. To the second of the above objections the answer is: Granted that a code cannot be made for all time, there is nevertheless no reason why any changes required by altered conditions of society should not be adequately met by periodical revision. A commission of lawyers might be appointed for that purpose, and revision might take place, say, every ten years. On the other hand, the arguments specially urged in favour of codification are: (1) That it will simplify the law, thereby getting rid of a vast mass of statutes and judicial decisions, whose

authority has become more or less doubtful, and which overload the book-shelves and waste the time of our lawyers and judges; and (2) that by simplifying the law it will be made accessible to and comprehensible by ordinary citizens.

Viewing the subject historically, we find that the Romans were the first to realise the idea of codification. The compilation of the Twelve Tables (q.v.) in 303 B.C. was the earliest attempt to codify the whole law, both public and private. But with the Romans the term code was confined in its application to the collections of the laws and constitutions promulgated by the emperors (the imperial *edicta*, *rescripta*, and *decreta*), and had not the extensive meaning of the word in its modern sense.

The following is an enumeration and description of the more celebrated codes, ancient and modern:

I. ANCIENT CODES.—(1) *Codex Gregorianus et Hermogenianus*.—These two collections of imperial constitutions (mainly of *rescripta*) were the first to receive the designation *codex*, and they supplied a model which was to a considerable extent followed in the subsequent codes of Theodosius and Justinian. They were both the work of private hands, although they were subsequently declared authoritative by a decree of Theodosius and Valentinian. The first of them is supposed to have been published about the end of the 3d century, and that of Hermogenianus a little later. Only fragments of each have been preserved.

(2) *Codex Theodosianus*, named after the Emperor Theodosius the Younger, during whose reign it was compiled. The original idea of Theodosius was to prepare a complete body of the law, collected from the writings of the jurists as well as the constitutions of the emperors, but his instructions to this effect were never carried out. The *codex*, as we have it, occupied three years in preparation, and was promulgated as law for the Eastern empire on 1st January 439, and a few days thereafter adopted and declared to be law for the Western empire by Valentinian III. This *Codex Theodosianus* has been in a great measure preserved. It consists of sixteen books, which are subdivided into titles, and a chronological order in the arrangement of the constitutions has been followed. All but the first five books (containing the purely private law) have come down to us. By means, however, of the so-called *Breviarium Alaricianum*—an abridgment in great part of this code made by the order of Alaric II., king of the Visigoths—it became possible to reproduce a considerable proportion of the earlier books. Palimpsest restorations have also during the 19th century brought to our knowledge a number of the genuine *constitutiones* which were not to be found in the breviary of Alaric. The best editions of this code are those of Jac. Gothofredus, with his celebrated commentary upon Books VI. to XVI., originally published in 1665, and Hänel, contributed to the *Corpus Juris Rom. Antejustin.* (Bonn, 1842).

(3) *Codex Justinianus*.—This, which is the most celebrated of the ancient codes, was named after the Emperor Justinian, in whose reign it was prepared. In the year 528 A.D. a commission of ten persons, with the famous Tribonian at their head, was appointed by Justinian to compile a code, incorporating in it the earlier codes of Gregorianus, Hermogenianus, and Theodosius, and also the various constitutions issued subsequent to these codes. The work was performed in fourteen months, and it was then declared that the new code should supersede the older compilation. A second edition of this work, revised and having a number of new enactments of Justinian himself incorporated, was promulgated in 534 under the name of the *Codex repetita praelectionis*. This is what has come down to us, and is now known as

the *Codex Justinianus*, and forms part of the *corpus juris*. It consists of twelve books, each of which is divided into chapters.

(4) *Romano-Barbarian Codes*.—Several collections were made of the laws of the barbarians of western Europe after they had become free from the domination of Rome. To three of these collections the name of the Romano-Barbarian Codes is usually applied. They are (1) the *Edictum Theodorici*, compiled under Theodoric, king of the Ostrogoths, about the year 500, and consisting of 154 sections (unsystematically arranged), dealing with all departments of the law, its materials being derived mainly from the Gregorian, Hermogenian, and Theodosian Codes. (2) The *Lex Romana Visigothorum*, prepared under Alaric, king of the Visigoths, and published in the year 506. This collection was one of great importance, and during a considerable part of the middle ages was treated as the principal exponent of Roman law, thus exercising great influence upon the Gothic law of western Europe. It was compiled by commissioners, appointed by Alaric, who derived their materials in great part from the Theodosian Code and the institutes of Gaius. This *codex* is commonly described as the *Breviarium Alaricianum*. (3) The *Lex Romana Burgundionum*, also published about the beginning of the 6th century, under Gundobald, king of the Burgundians. It was compiled from much the same sources as the code of Alaric II.

II. MODERN CODES.—As already observed, the idea of a code in the modern sense—viz. as a complete statement of the whole law, or any particular department of it—was not realised by the ancients. The Roman *Codex* was in many respects more akin to what we call a consolidated statute than a proper code.

(1) *Prussian Code*.—The first of the modern codes (leaving out of view certain *ordonnances* of a general nature promulgated at an early date in France and some other countries, but which hardly deserve the appellation Code) was the celebrated *Landrecht* of Prussia—the *Code Frédéric*—published in 1751. This work was due to the genius of Frederick the Great, and was intended by him to firmly cement the union between the various parts of his kingdom. In the introductory plan (or *projet*), Frederick tells what induced him to undertake the work—viz. the great uncertainty in the law arising out of the want of uniformity in the customs and statutes prevailing in the different parts of his dominions, and the excessive and costly litigations due to this uncertainty. He makes, at the same time, a violent onslaught upon lawyers generally, and hopes that one immediate result of the code will be to restrict their number to the most moderate dimensions. Out of this *Code Frédéric*, the existing *Allgemeines Landrecht* of Prussia has grown.

(2) *Code Napoléon*.—This is the most celebrated of the modern codes. At the time of the great Revolution there was an endless variety of particular laws and customs (*droit écrit et droit coutume*) prevailing in the different parts of France, entailing great uncertainty and expense in the administration of justice, and preventing anything like true solidity and unity in the nation. It was Napoleon's merit that he realised that the best remedy for this lay in the unification of the law by a code which might be made applicable to the whole country. No doubt, a good deal had been done towards unification by the preparation of an admirable act of *ordonnances* in the reigns of Louis XIV. and Louis XV., but they only went a small way in rectifying the evils. Napoleon, accordingly, gave directions for the carrying out of this project, and it was executed with astonishing celerity. The *Code Napoléon*, as we now have it, was published

and promulgated between 1804 and 1810. It consisted of five parts—viz. the 'Code Civil,' dealing with the main body of the private law; the 'Code de Procédure Civile;' the 'Code de Commerce,' dealing with the laws relating to commercial affairs; the 'Code d'Instruction Criminelle;' and, finally, the 'Code Pénal.' Each of these five parts was independent of the others, though prepared on the same system and governed by a uniformity of plan. In order to prevent absolutely an appeal in any case to the authority of the old laws and customs, it was expressly enacted that if cases should occur for which the code had made no provision, the judge should decide according to what he might consider to be good sense and equity or ancient custom—in this respect differing from the Prussian *Landrecht*, which requires that any questions unprovided for by it shall be referred by the judge to a legislative commission for decision. The *Code Napoléon* (or, as it has been re-christened under the Republic, the *Code Civil*) remains in force as the law of France at the present day, and despite many defects in its original construction—necessitating a large number of interpretative commentaries—it has, beyond doubt, proved a great boon to that country. Napoleon himself is said to have been prouder of it than of any of his victories. 'I shall go down to posterity,' he said, 'with my code in my hand.' But probably the best test of its excellence is that it has been (in whole or part) the model for a large number of continental codes; as, for example, those of Belgium, Italy, and Greece. So also in the Rhenish provinces, upon which it was originally imposed by force, it remains to this day the basis of legislation.

(3) *German Codes*.—Prior to the constitution of the present German empire in 1871, two important codes of the German commercial law had been prepared and adopted by the North German Confederation. These were the *Wechsel-Ordnung*, codifying the laws relating to bills of exchange, which was published in 1848, and the *Allgemeines Handelsgesetzbuch*, codifying the whole commercial law, exclusive of bills of exchange and bankruptcy, which was published in 1861. Since 1871 these two codes have been made applicable to the whole of the empire, and three other departments of the law have since been codified—viz. the law of bankruptcy (*Konkurs-recht*), the law of procedure, and the criminal law. And in 1888 a commission was sitting at Berlin charged with the enormous task of codifying the whole civil law of Germany.

(4) *United States Codes*.—In most of the states codification, either of the whole law or of particular branches of it, has been effected. At the same time it is noticeable that in one or two of the states the expediency of codifying the private law is still much controverted. This is particularly the case with the state of New York, where in 1857-65 a draft civil code was prepared (mainly by the distinguished jurist, Mr Dudley Field), but did not receive the sanction of the legislature. This draft civil code has, however, been adopted by California and Dakota.

(5) *British and Colonial Codes*.—The only result in the way of codification achieved in the United Kingdom is in the department of the law which relates to bills of exchange (including promissory notes and cheques). By the Bills of Exchange Act, 1882, the statute and common law of the three kingdoms relating to this important department of mercantile jurisprudence was in great measure reduced to the form of a code. This enactment is, perhaps, not a complete code in the strict sense, seeing that it does not profess to entirely shut the door of the common law in questions affecting bills—decisions prior to the Act

being still authoritative so far as they are not inconsistent with its express provisions. But in other respects it fulfils the proper requirements of a code. Having been drafted with much care and skill, it has, since it came into force, proved of great value and benefit to the mercantile community in the way of diminishing litigation and otherwise. Efforts have been and are now being made by law-reformers (prominent among them being Lord Justice Stephen) to have other branches of the law codified, and more particularly the law of evidence and the law of crimes, and criminal procedure. As regards British possessions it may just be observed that an excellent code exists in Canada, and that in India several branches of the law have been codified by the celebrated Anglo-Indian codes. The criminal code of India was drawn up in the year 1837 under the auspices of Lord Macaulay, though it was not promulgated till 1860.

Codeine, an alkaloid obtained from poppy-heads. See POPPY.

Codex (Lat., 'manuscript,' pl. CODICES: see CODE), the name applied to ancient manuscripts, as of the classics or of the Scriptures. Of the latter class the four great Uncials (q.v.) are the Codex Sinaiticus, discovered in 1844 and 1859 in the monastery of Mount Sinai by Tischendorf, and the Codex Vaticanus, both of the 4th century; and the Codex Alexandrinus (see under ALEXANDRIA) and Codex Ephraemi of the 5th century. All four originally contained the Old and New Testament complete, but none are perfect copies, while the last, besides having great lacunæ, is almost illegible. See PALIMPSEST.

Codicil (Lat. *codicillus*, diminutive of *codex*), a supplement to a will, whereby anything omitted is added, or any change demanded by the altered circumstances of the testator or the beneficiaries, is effected. A codicil is authenticated in the same manner as a will, and possesses the same privileges when holograph, or written by the hand of the testator himself. See WILL.

Codilla is the coarsest part of hemp and also of flax, sorted out and separated from the rest.

Codlin Moth (*Carpocapsa pomonana*), the moth whose larvæ cause the 'worm-eaten' apples, which fall prematurely off.

Cod-liver Oil is generally obtained from the livers of the common Cod (q.v.), but likewise from allied species, as ling, dorse, coal-fish, torok, &c. In these fish the Adipose Tissue (q.v.) containing oil is almost entirely confined to the liver, in which they agree with the shark tribe, whilst in other fish, as in the herring and salmon, the oil is diffused over the entire structure of the animal. The supplies of medicinal cod-liver oil used to be derived mainly from Newfoundland, but Norway now supplies the bulk of that used in Great Britain. The most famous of the Norwegian fishing-grounds is that of the Lofoden Islands. On the outer shores of these islands immense shoals of fish begin to arrive in December, but owing to the storms to which the coasts are liable, only a comparatively small number of boats (some 800) engage in the fishing. Later on, in the beginning of January, the fish pass in between the islands and enter the calmer waters of the Westfjörd to spawn. Then the fishermen, assembling in immense numbers, catch the fish by net or baited line. A good catch for a boat, with a crew of five men and a boy, is from 600 to 1200 fish; and some idea of the importance of this industry is obtained from the fact that in a single year these fisheries alone employed 4000 vessels, with a crew of 27,000 men, the catch amounting to 25,000,000 of fish. The fishing-grounds being near the shore, the

fish are at once cleaned, and the livers removed. These may be treated in different ways, the various qualities of cod-liver oil being the result. The finest oil, known as 'non-freezing pale oil,' is obtained by warming the livers by means of steam heat, when the oil separates, and is either removed by straining or by allowing it to float to the surface. It is then cooled to 14° (-10° C.), and filtered, either by mechanical pressure or in the usual way. A white tallow-like substance remains in the flannel filter, and a bright cod-liver oil passes through, which is now capable of being exposed to frost without turning turbid.

In the case of those fisheries which are situated at some distance from the shore, the livers are placed in tanks, till a sufficient quantity has been collected, with the result that partial putrefaction takes place. The oil obtained in this way is of a dark-brown colour, and possesses a nauseous empyreumatic taste.

A still coarser variety is manufactured for use in leather-making. In it the livers of the cod, herring, haddock, &c. are indiscriminately used, a very fishy-tasted oil being the result.

It will be seen from the above that the different varieties of cod-liver oil may be produced from the same livers. Thus, that obtained by pressure or steam heat from fresh livers is the freest from taste and colour, while the oil becomes darker and darker as the livers become less fresh. It has been supposed by some authorities that the dark-brown oil is the more efficacious, but others find no difference in actual practice, while the pale oil can alone be tolerated by delicate stomachs. Cod-liver oil mainly consists of oleic, stearic, and palmitic acids, in combination with glycerine. In addition to these, *gaduin*, a substance of biliary origin, but possessing no recognised medicinal virtues, is present along with iodine and bromine. Some have ascribed the virtues of cod-liver oil to the iodine or bromine, but as the iodine is only present in the proportion of 1 part in 2000 parts of the oil, this view seems untenable. Sometimes the oil is adulterated with spurious oils, to which iodine has been added, and this may be assumed if the proportion of iodine exceeds that stated above. There are unfortunately no chemical tests that can with certainty detect the presence of other oils, although there are tests which distinguish liver-oils from those of other origin. Thus with nitric acid, cod-liver oil yields a purple colour, changing to a brown; while a drop of sulphuric acid produces a violet colour, soon changing to brownish red. In order to prevent it from becoming rancid and fishy-tasted, it is well to keep it secluded from the air.

Cod-liver oil is at present one of the most important remedies in the *Materia Medica*. Although possessing a high reputation on the Continent, it was not till 1841, when Professor Hughes Bennett (q.v.) of Edinburgh wrote a treatise on it, that it came into general use in Britain. It is most valued in cases of pulmonary consumption, chronic rheumatism, and gout, besides all diseases of a scrofulous nature. In all these it is, however, useless to expect good results unless the remedy has been regularly taken for several weeks. Its mode of action is uncertain. While some hold that it merely acts as a nutrient, it is certain that pork-fat, butter, and other digestible oils, do not have the same specific action that characterises cod-liver oil. It is given in doses of from half a teaspoonful to one tablespoonful three or four times a day, and it does not seem that excessive doses, such as a cupful or more, are of any real benefit, while they are a severe strain on the digestive organs.

As its peculiar flavour is very repulsive to many patients, various devices have been adopted to

render it more palatable. The addition of a trace of sulphuric ether, while rendering it more easily digested, does not improve the flavour. It may, however, be made into a jelly with isinglass, or be taken floating on the surface of porter; while in the form of *Emulsion*, of which many varieties are in the market, the flavour is more or less skilfully disguised. Most druggists also keep gelatin capsules, containing from one to one and a half teaspoonful, which are easily swallowed.

Codogno, a town of Northern Italy, 17 miles SE. of Lodi by rail. Pop. 8935.

Codrington, SIR EDWARD, a British admiral, was born of a good old Gloucestershire family, 27th April 1770, and entered the navy in 1783. In 1794 he was lieutenant of Lord Howe's flagship, and took a prominent part in the action off Ushant on the glorious 1st of June. At Trafalgar, in 1805, he was captain of the *Orion*, and leader of a squadron. He afterwards served in the North Sea, in Spanish waters, and in North America, and rose to the rank of vice-admiral in 1821. In 1826 he was appointed commander-in-chief of the Mediterranean squadron, and in that capacity took the leading part in the battle of Navarino (q.v.), which destroyed the Turkish navy. In reward for this victory he received the Grand Cross of the Bath, with Russian and French orders; but the battle being considered an 'untoward event,' Codrington was recalled. He attained the full rank of admiral of the red in 1837, and in 1839 was appointed commander-in-chief at Portsmouth. He was M.P. for Devonport from 1832 to 1839. He died April 28, 1851. The 'Narrative' written to prove that at Navarino he had not exceeded his instructions, is printed in the *Memoir* by his daughter, Lady Bourchier (2 vols. 1873).—His son, GENERAL SIR WILLIAM JOHN CODRINGTON, G.C.B. (1804-84), was commander-in-chief in the Crimea from 11th November 1855.—Another son, ADMIRAL SIR HENRY JOHN CODRINGTON, K.C.B. (1808-77), took part in the destruction of St Jean d'Acre, and served in the Baltic in 1854-55.

Codrus, the last king of Athens, was the son of Melanthus, and according to Greek legend, sacrificed his life for his country about the year 1068 B.C. A war raging between the Athenians and Dorians, the oracle declared that the victory should belong to those whose king was slain by the enemy; whereupon Codrus, attiring himself as a peasant, entered the Dorian camp, and having picked a quarrel with some of the soldiers, contrived to have himself slain. See ARCHON.

Coefficient, the numerical or literal factor prefixed to an unknown quantity in any algebraic term. Thus in the expression $ax - 2by^2 + \sqrt{3}x^2 - (a+5)y$ there are four terms, and the coefficients are, in order, a , $2b$, $\sqrt{3}$, and $(a+5)$. A special and very important instance is found in the phrase *Differential Coefficient* (q.v.) of a given function with reference to one or more of the variables involved. In the theory of equations, also, coefficients play an important part: thus, in the cubic $x^3 + ax^2 + bx + c = 0$, we know that (supposing the 3 roots are p , q , r) $p + q + r = -a$, $pq + qr + rp = b$, and $pqr = -c$.

Coehoorn, or COHORN, MENNO, BARON VAN, called the Dutch Vauban, was the son of a captain of infantry, and born near Leeuwarden in 1641. He studied fortification and mathematics at Franeker, and already captain of a company in his sixteenth year, he greatly distinguished himself at the siege of Maastricht, and in various battles. At the siege of Grave, in 1673, he demonstrated that the small portable mortars named after him might

be advantageously employed. Coehoorn covered himself with honour at Seneff (1674), before Kaiserswerth (1689), and at Fleurus (1690). He fortified Namur, and defended it against Vauban in 1692; besieged that fortress in 1695, and retook it; was appointed lieutenant-general and director-in-chief of the Dutch fortifications, and fortified several towns, of which Bergen-op-Zoom was considered his masterpiece. In the war of the Spanish succession he defeated the French more than once, and took Huy and Limburg. He died at the Hague, on his way to meet Marlborough, March 17, 1704. He left two important works on fortification.

Coehorns—named from the military engineer who introduced them—are small bronze Mortars (q.v.), $\frac{3}{4}$ cwt. in weight, and of $4\frac{1}{2}$ inches calibre. Being easily carried, they are useful in sieges, to annoy working parties, and in situations where guns cannot be employed, such as the attack of hill-forts in India.

Cœlenterata, the technical name for the second lowest alliance of many-celled animals. The class includes (1) locomotor types—jelly-fishes, swimming bells or medusoids, colonial medusoids such as the Portuguese Man-of-war, and extremely active organisms known as Ctenophores; (2) tubular forms or 'polyps' (mostly fixed)—the common Hydra, the compound Hydroids or zoophytes, the sea-anemones, compound sea-anemone-like types such as Dead-men's Fingers, and limy or coral modifications from all these. The two types, medusoid and polypoid, are inseparably linked together by real though not obvious resemblance in structure, and by the facts that many swimming bells are only detached and modified reproductive members of fixed zoophyte colonies, and that a fixed polypoid stage occurs as a chapter in the life-history of some common jelly-fishes.

General Characters.—(1) The Cœlenterates are nearer the primitive two-layered sack-like ancestral form, the Gastrula (q.v.), than are higher animals; (2) they are radially symmetrical in almost all cases, that is, they are the same all round, and a line drawn vertically through the body of Hydra, Sea-anemone, or Jelly-fish corresponds to the long axis of the gastrula; (3) they do not possess any body-cavity distinct from the alimentary tube; (4) they have not a distinctly developed third or middle layer of cells, as in higher animals; (5) there is an almost constant presence of offensive stinging cells; (6) vegetative multiplication by budding is very common, and division of labour is frequent in the resulting colonial organisms; (7) the life-history often illustrates Alternation of Generations (q.v.); (8) 'coral' forms occur abundantly by the formation of limy 'skeletons' in various passive types.

Classification.—(a) The Hydroids and the swimming bells often associated with them, the jelly-fish proper, colonial locomotor colonies like the Portuguese Man-of-war (q.v.), the limy Hydrocoralline (see MILLEPORES), &c., are grouped together as Hydrozoa. (b) The Sea-anemone and Dead-men's Finger types, with their associated 'corals,' form the division known as Actinozoa (q.v.). (c) The climax of activity is represented by the Ctenophora (q.v.), such as *Berœ* (q.v.). For details and fossil forms, see separate articles.

Habit of Life.—Five or six Cœlenterates, including the common Hydra, are fresh-water animals; the others are marine. A few are parasitic. Most of the active forms are found in the open sea, near the surface, but some live at great depths. The sedentary forms occur at all depths, and are often anchored on other animals, which they sometimes mask. The food of the great majority consists of small organisms, in the seizure

of which the almost constant tentacles and stinging cells are very important.

Relationships.—For the connections between Hydra and the compound zoophytes, between the polypoid and medusoid types, between the medusoids and the Portuguese Man-of-war order, between medusoids and Ctenophores, between Sea-anemones and the sessile type exhibited in the life-history of some jelly-fishes, see separate articles (*ANEMONE*, *BERœ*, *CORAL*, *CTENOPHORA*, *HYDROID*, *JELLY-FISH*, &c.).

Pedigree.—The ancestral Cœlenterate was probably gastrula-like. Modification has taken two main directions of increasing activity and increasing fixedness. The class as a whole probably arose apart both from the lower Sponges and from all the higher animals. See Huxley's *Anatomy of Invertebrates*, and other general works of Claus, Gegenbaur, Rolleston and Hatched Jackson, Zittel, &c., and monographs noted under special articles.

Cœlestinus. See CELESTINE.

Cœle-Syria ('Hollow Syria'), now called by the natives El-Buk'â, 'the deep plain,' a valley of Syria, extending between the ranges of the Lebanon and Anti-Lebanon. It is 1706 feet above the sea, and is watered by the Orontes (now El-Asi). Above the valley stand the ruins of Baalbek.

Cœliac Axis. See AORTA.

Cœnobites (Gr. *koinos*, 'common,' and *bios*, 'life'), the name given to those monks who live together, in contradistinction to anchorites or hermits, who withdraw from all society, and live in a solitary fashion. See MONACHISM.

Cœnurus. See BLADDER-WORM, CESTOID WORMS, TAPEWORM.

Coffee (Turkish *qahveh*, from Arabic *qahveh*, originally meaning 'wine'). This well-known beverage is an infusion of the roasted seeds of the coffee-tree (*Coffea Arabica*), a native of Abyssinia, Arabia, and many parts of Africa, and naturalised in many of the tropical countries colonised by Europeans. There are some twenty species of *Coffea*, but few of them seem to possess valuable properties; the seeds of *C. Mauritiana*, prepared in the same way, are bitter and slightly emetic. The genus belongs to the natural order Cinchonaceæ. It has a tubular 4-5-cleft corolla, and a succulent fruit containing two cells lined with a cartilaginous membrane, and each containing one seed.

In a wild state, it is a slender tree of 15-25 feet high, with few branches; in cultivation, it is seldom allowed to become more than 6-10 feet high, and is made to assume a sort of pyramidal form, with horizontal branches almost from the ground. The leaves are evergreen, opposite, very shining, oblong, and leathery; the flowers are small, clustered in the axils of the leaves, and snow-white; the whole appearance of the tree is very pleasing; and the smell of the flowers is delicious. The fruit, when ripe, is of a dark-scarlet colour, and the seeds are semi-elliptic and of a horny hardness. The seeds are commonly but incorrectly termed *coffee beans*, or, still more incorrectly, *coffee berries*.

The coffee-tree succeeds only in countries where the average temperature of the year is about 64-70° F. In Peru and Quito it is acclimatised at an elevation of 6000 feet, where, however, frost never occurs; but as it delights in a moist atmosphere, it nowhere thrives better than in tropical islands. In the hothouses of Britain the coffee-tree frequently flowers and the fruit ripens. Coffee plantations are laid out pretty much in the same way everywhere. In quadrangles, bordered by fruit-trees, the coffee-trees stand in rows; they are pruned to the same height, and the ground between

them is carefully kept clear of weeds. Where the climate is dry, abundant irrigation is necessary, but the supply of water is cut off as the fruit begins to ripen, in order to improve the aroma of the seeds. The tree yields its first crop in the third year; from a full-grown tree it may amount to a pound of coffee beans. As the coffee-tree continues flowering for eight months, its fruits are at any given time of very unequal ripeness; in the West Indies and Brazil, three gatherings are

Coffee; branch with fruit.

therefore made annually. The beans are placed on mats or large floors specially adapted for the purpose, where they are dried by the sun's rays, being meanwhile frequently turned. They are passed between rollers to remove the dried pulp of the bean, and the membrane which incloses the seeds themselves. The coffee is afterwards freed from impurities by winnowing, and conveyed in bags to the seaports. As equal care is not, however, bestowed upon the preparation of it in all places where it is cultivated, there are great differences in quality and price.

The earlier history of the coffee-tree is not very clear. Coffee was not known to the Greeks or Romans; but in Abyssinia and Ethiopia it has been used from time immemorial. In Arabia it was certainly in use in the 15th century, and over the rest of the East in the 16th century. Towards the end of the 17th century, the coffee-tree was carried from Mocha to Batavia by Wieser, a burgomaster of Amsterdam, where it was soon extensively planted, and at last young plants were sent to the botanical garden at Amsterdam, from which the Paris garden obtained a tree. A layer of this was carried out to Martinique in 1720, where it succeeded so well, that in a few years all the West Indies could be supplied with young trees.

The following sorts are particularly distinguished from each other in commerce. *Mocha Coffee*, which comes from Arabia, and is known by its small gray beans inclining to greenish; *Java* or *East Indian Coffee*, which has large yellow beans; *Jamaica Coffee*, with beans somewhat smaller and greenish; *Surinam Coffee*, which has the largest beans; *Bourbon Coffee*, with beans pale yellow and almost whitish. The devastation of the Ceylon plantations by the leaf disease (see CEYLON) has led to the

introduction of a hitherto neglected variety, the *Coffea Liberica*, or *Liberian Coffee*, a native of the west coast of Africa. It appears to resist the ravages of the disease which has been so fatal to the Arabian variety in Ceylon; but being of coarser character, it is grown only to a very small extent.

The great demand for coffee has led to the employment of a number of cheaper substitutes, of which Chicory (q.v.) root is the best known. Of others, dandelion root, carrot, and the seeds of the common yellow iris may be mentioned. They are prepared by roasting like coffee. The seeds of *Astragalus Baticus*, are known on the continent of Europe as *Swedish Coffee*, and are said to be the best substitute for coffee yet discovered. But all these substitutes want the most important constituent of true coffee, *caffeine*; and are therefore very different from it in their qualities. Ground coffee is subject to great adulteration, as will be seen from the article ADULTERATION.

In France and other continental countries, ground coffee is largely mixed with caramel or burnt sugar. This is for the most part prepared by skilfully roasting the 'foots' or dregs obtained in the refining of sugar. In moderate quantities it imparts a flavour considered by many to improve the infusion. The so-called 'French coffee' now so largely sold in England contains more or less of caramel—commonly much more than is desirable, its commercial value being very small. A rough test or indication of this is easily obtainable by dipping a bright silver or plated spoon into the infusion. The caramel infusion adheres to the spoon much more decidedly than the pure coffee infusion, and leaves a darker stain. Infusion of chicory behaves similarly to that of caramel.

The leaves of the coffee-tree are used in the western part of Sumatra instead of the seeds. They are prepared by quick drying in a manner similar to that in which tea-leaves are prepared; and in this state contain even a larger proportion of caffeine than the coffee beans of our shops.

Coffee owes its exhilarating and refreshing properties to the presence of three substances: (1) *Caffeine* (q.v.), which occurs in the roasted bean to the extent of $\frac{1}{2}$ to 1 per cent.; (2) a *volatile oil*, which is not present in the raw bean, but is developed during the process of roasting to the extent of only one part in about 50,000 of the roasted coffee; and (3) astringent acids, resembling tannic acid, but called *caffeo-tannic* and *caffic acids*. The average composition of un-roasted coffee is as follows:

Caffeine	0.8
Legumin (vegetable Caseine) (q.v.)	13.0
Gum and sugar	15.5
Caffeo-tannic and Caffic acids	5.0
Fat and volatile oil	13.0
Woody fibre	34.0
Ash	6.7
Water	12.0
	100.0

When the beans are roasted till they assume a reddish-brown colour, they lose 15 per cent. by weight, and gain 30 per cent. in bulk; when further roasted till they become chestnut brown, they have lost 20 per cent. by weight, and increased 50 per cent. in bulk; whilst if the roasting is continued till the beans become dark brown, they lose 25 per cent. in weight, and acquire 50 per cent. in bulk. When the roasting is carried too far, more or less charring is the result, and a disagreeable burnt smell is produced, which tends to overcome the natural pleasant aroma.

In Britain coffee is usually under-roasted, probably in order to escape the loss of weight, as the roaster is also the retailer. But in France, in Norway, in Germany, and other countries where it

is roasted at home by the consumer, the roasting is carried to the dark-brown stage. The writer, who has watched the domestic roasting of coffee in many countries, attributes the superiority of the pure infusion made in these countries mainly to this and the use of the freshly roasted and ground coffee. The Norwegian peasant usually adds a very small quantity of butter to the beans while roasting in the simple apparatus, like a covered shovel or frying-pan, she uses; always shaking it while over the fire. Every tourist praises the result.

The important offices which coffee fulfils are, to allay the sensation of hunger; to produce an exhilarating and refreshing effect; and, according to some authorities, to diminish the amount of wear and tear, or waste of the animal frame, which proceeds more or less at every moment. See NUTRITION.

An endless variety of apparatus have been contrived—some of them of great complexity—for preparing coffee for the table. The chief object aimed at is to obtain the liquor free from all sediment. The simplest and cheapest device is that of placing a bag or metal strainer—by means of a suitable rim—in the upper part of the coffee-pot, placing the ground coffee in this, and pouring boiling water through it. Or the ground coffee may be simply placed in a saucepan or coffee-pot, hot water poured upon it, and boiled for a few minutes. After this the grounds will settle down, and the coffee may be poured off fairly clear.

Many forms of coffee-pot have been devised in which atmospheric pressure is applied for forcing the hot water through the ground coffee resting upon a metal strainer, doing this in such a manner that the water shall all pass through while just at the boiling heat, and then shall leave it.

The question whether coffee should be boiled at all, or simply infused like tea by pouring boiling water on it, has been much discussed. The writer has observed that in countries where pure coffee is used, boiling is practically in favour. This suggested some experiments which have shown that pure coffee is improved by two or three minutes' boiling, while chicory is rendered bitter and unpalatable by such treatment. We therefore recommend that where a sufficient quantity of mixed coffee is prepared to render it worth while to take the trouble, the chicory should be separately infused like tea, the coffee boiled, and the two then mixed. Soyer recommends that, before the boiling water is poured in, the saucepan should be set dry on the fire, and the powder stirred till it is quite hot, but not in the least burned. In France, an equal measure of boiling milk is added to a very strong infusion in making *café au lait*. The chief effect of adding chicory to coffee is to deepen the colour.

It should be understood that when milk is added to coffee it should be boiled; cream may be used without boiling. The Turks drink it thick with sediment; some Arabs make a tea-like beverage from the dried pulp; the Somali boil the berries in oil, and soak maize in the mixture. Raw coffee beans are improved by age. A large domestic stock may therefore be laid in advantageously.

ESSENCE OF COFFEE is a highly concentrated infusion, mixed to the consistence of treacle with extract of chicory and burnt sugar, and kept in well-corked bottles. By pouring boiling water upon a teaspoonful of the essence, a cup of very tolerable coffee may be prepared in a moment. See Lester Arnold, *Coffee: its Cultivation and Profit* (1886); C. G. W. Lock, *Coffee: its Culture and Commerce in all Countries* (1888).

Coffee Bug (*Coccus* or *Lecanium adonidum*), one of the plant lice (see COCCUS), often very destructive to coffee plants.

Coffee-houses were first heard of in Europe at Constantinople, in the middle of the 16th century, and are spoken of as among Turkish habits by Burton (1621) and Bacon (1627). They were introduced at Venice in 1645. Jacobs, a Jew, opened one at Oxford in 1650. The first in London was set up about 1652 in St Michael's Alley, Cornhill, by Pasqua Rosee, a Ragusan. The Rainbow was the second (1656). The first coffee-house in France was opened at Marseilles in 1671, and some years later an Armenian kept one in Paris. The Café Procope (1725), the first of the Parisian literary cafés, was founded by a Sicilian, Procopio Cultelli. The Régence became favoured in after-years by the *romantiques*. Coffee-houses were established in Sweden in 1674, at Hamburg in 1679, and at Vienna in 1683. In 1675 an attempt was made by Charles II. to suppress them by proclamation as the resort of political agitators. For nearly a century they were in England much what they have remained in France to the present day, free and open clubs. Among the most famous were Garraway's, where tea was first retailed, and Jonathan's, both in Change Alley, the latter the stock-jobbers' resort; Dick's; Lloyd's (q.v.); the Jerusalem, one of the earliest city news-rooms; Don Saltero's, at Chelsea, with an absurd museum of curiosities; St James's, the resort of the Whigs from the reign of Queen Anne to the close of George III.; and Wills's, the predecessor of Button's, and the resort of Dryden. Addison and Swift patronised Button's. Other coffee-houses were Tom's in Birch Lane, Cornhill; the Bedford, Tom King's, and the Piazza, in Covent Garden; the Chapter in Paternoster Row; and Child's in St Paul's Churchyard. Cocoa and chocolate houses were coffee-houses under other names. The modern philanthropic coffee-tavern system was first promoted by Mr and Mrs Hind Smith in 1807. In 1875 a number of cocoa-houses were started in Liverpool, and at the present time about four hundred temperance coffee-houses, owned by public companies, are prospering in various towns of Great Britain. Modern coffee-houses are eating-rooms without excise licenses, and French cafés-chantants merely music-halls.

Cofferdam, a watertight structure used in engineering for excluding the water from the foundations of bridges, quay walls, &c., so as to allow of their being built dry. Cofferdams are generally formed of timber piles driven close together (called sheeting) in two or more rows, according to the depth of water and the nature of the bottom; the space between the rows, which may vary from 4 to 10 feet, being spooned out, down to the solid and impervious bottom, and filled up with clay puddle. Sometimes they are made of only one row of piles of the full height, caulked above low-water, with a low or dwarf row outside to confine the puddle up to that level, or, where there is no wave or current, with a mere bank of clay thrown against the outside; and occasionally the upper work is formed of horizontal planking, fixed on open main piles, and caulked in the joints. When the bottom is rock, so as to prevent piles being driven, and is not much below low-water, cofferdams are occasionally formed of two stone walls, with a space between filled with clay. Cofferdams require to be strongly shored within, to prevent their being forced inwards by the pressure of the external water; and the rows of piles require to be strongly bolted together, to resist the pressure of the clay puddle, which otherwise would burst them. This method of founding is now seldom practised; it is costly and obstructive to the stream.

In the construction of the Victoria Embankment on the river Thames, between Blackfriars and Westminster Bridges, $1\frac{1}{4}$ mile in length, the coffer-

dams were constructed of wrought-iron Caissons (q.v.) or boxes, in substitution for ordinary timber dams; on the suggestion of Sir Joseph Bazalgette, in order to effect a saving by using the same caissons two or three times successively in different parts of the dam. The caissons were oval, 12½ feet long, 7 feet wide, joined end to end, and made watertight at the joints by felting. In about two-thirds of the length of the embankment, 195 caissons were employed.

Coffer-fish (*Ostracion*), a peculiar genus of bony fishes in the small order Plectognathi, and in the family Sclerodermi, which also includes the file-fishes. The body is inclosed in a firm box formed of hexagonal bony scales fitted into one

Coffer-fish.

another like a mosaic. The snout, the bases of the fins, and the end of the tail are the only soft-skinned parts. Over a score of species are known from tropical and subtropical seas. The best-known form is *O. quadricornis* from the tropical Atlantic. See GLOBE-FISH, and SUN-FISH.

Coffin (Lat. *cophinus*, Gr. *kophinos*, in both languages signifying a basket, coffer, or chest, but never a coffin). Coffins for the bodies of the dead constructed of wood are known to have been used in prehistoric times in Europe. The earliest form of the wooden coffin is simply a suitable length of an oak-tree trunk split, and hollowed out for the reception of the body. Two such coffins containing the skeletons of a man and a woman of the bronze age, with their clothing undecayed, and their weapons, are preserved in the museum at Copenhagen. The wooden coffins of the iron age were sometimes of tree trunks, and at other times of hewn planks fastened with clinker nails. From Bede we learn that the Saxons occasionally employed wood; but the common people, both then and in the subsequent Norman and English eras, were simply wrapped in cloth, and so put into the ground. The same custom seems to have been followed with monks down to a comparatively recent period, and is still in use among the poorer classes in the East. See EMBALMING.

It has been keenly disputed amongst scholars, whether it was more usual with the Greeks to bury their dead or to burn them (see BURIAL); but both customs unquestionably prevailed. Greek coffins were called by various names (*soroi*, *puoi*, &c.), and composed of various materials, the most common being baked clay, or earthenware. Their forms also varied. In Rome the ancient practice was to bury the dead, not to burn them; though under the Empire, and previous to the recognition of Christianity, the latter custom became almost universal. The coffin in Rome was called *arca* or *loculus*, and was frequently made of stone, sometimes of a peculiar kind of stone brought from Assos, in Troas, which was said to consume all the body except the teeth in forty days, and which, from this circumstance, was called sarcophagus—an eater of flesh (see SARCOPHAGUS). Roman stone coffins, both of the heathen and early Christian time, have been found in Britain. Cremation was repugnant to the feelings of the primitive Christians, who buried their dead in receptacles of stone. These were either hewn out

of the rock as in the catacombs, or were sarcophagi elaborately sculptured with scenes from Scripture history and emblems of the faith. The simplest form of stone coffin was that used in prehistoric

Roman Stone Coffin, found at York.

times throughout Europe, consisting of unhewn stones set on their edges, so as to cover the sides and ends of the grave, one or more flat stones being then laid over the body to form a lid. This form of rude stone cist or coffin was continued long after the introduction of Christianity in most European countries, and many ancient cemeteries, formerly regarded as pagan and prehistoric, are now recognised as Christian by the orientation of their stone-lined graves. To these succeeded stone coffins, which were commonly used for persons of the higher classes throughout the middle ages; and so late as 1686 the antiquary Dugdale was buried

Stone Coffin, Temple Church, London.

in a stone coffin. These stone coffins were generally of a single block, commonly tapering from the upper end. In the hollow for the reception of the body, there was from the 12th century a part peculiarly fitted for the head, and a hole in the bottom to allow of the escape of moisture. Such coffins, for the most part, were not buried deeply in the earth, and were frequently placed so near the surface that the lids were visible, which, within a church, often formed part of the pavement, and were covered with elaborate sculpture representing crosses and other ornaments. Sometimes they were even above the ground altogether, and thus became the originals of the table-tombs and altartombs of the middle ages. Leadern coffins were also occasionally used in the middle ages, as those in the Temple Church in London testify, but the slight wooden cases now in common use appear to be of comparatively recent origin. The practice of surrounding the wooden shell with a coffin of lead, and inclosing both in an oak casket, is, for sanitary reasons, to be discouraged. Even a wooden coffin, if well made, greatly retards decomposition, and keeps the process long incomplete; and to remedy this the use of wicker coffins, of white or stained osiers, has been suggested. In America, however, zinc or copper lining and lids of heavy French glass are employed by undertakers to render their work as far as may be airtight and indestructible; and of late years caskets of zinc or copper, and even of iron or rolled steel, have come into use. The modern hexagonal form of coffin is peculiar to Great Britain. The sides of the American casket are parallel, the ends either rounded or broken into three panels; the exterior is sometimes ornamented with carved work,

but is more commonly covered and draped with broadcloth, velvet, or satin, fringed and tasseled. Expensive woods and silvered handles and nails are frequently employed: and the lid is furnished with a face glass, which is generally removable. The French and German coffins follow largely the same lines, but without the ornamentation which distinguishes the American casket.

Coggeshall, a town of Essex, on the Blackwater, 44 miles NE. of London. It has a school, founded by Sir Robert Hitcham (1636), remains of a Cistercian abbey (1142), a good Decorated church (restored 1868), and some manufactures of silk, velvet, and lace. It is supposed to have been the Roman *Canonium*, and the remains of a Roman villa have been found. John Owen was minister here. Ralph de Coggeshall, abbot here (1207-18), wrote a *Chronicon Anglicanum* (of the period 1161-1224), edited by J. Stevenson in 1875. Pop. 3830.

Cognac, a town of France, in the department of Charente, on an old castle-crowned hill over the Charente, 42 miles SE. of Rochefort by rail. The cultivation of the vine and distillation of Brandy (q.v.) form the chief industry of the district; in the town, casks and bottles are manufactured. Francis I. was born here. Pop. (1872) 12,950; (1886) 14,537.

Cognate. See AGNATE.

Cognizance, in Heraldry, a Badge (q.v.), in the more restricted sense of that term.

Cognoscenti (Ital., from Lat. *cognosco*, 'I know'), persons professing a critical knowledge of works of art, and of a somewhat more pretentious character than amateurs.

Cogno'vit (viz. *actionem*, 'he has confessed the action'), in the law of England, is the defendant's written confession that the plaintiff's cause against him is just and true. By this confession before or after issue, the defendant suffers judgment to be entered against him without trial, in which case the judgment is called judgment by confession.

Cogswell, JOSEPH GREEN, LL.D., American bibliographer, born at Ipswich, Massachusetts, in 1786, studied at Harvard and Göttingen, and was professor of Geology at Harvard from 1820 to 1823, when he established the Round Hill School with Bancroft (q.v.). He was for some years editor of the *New York Review*, and, with Halleck and Washington Irving, assisted in planning the Astor Library, of which he was for many years superintendent. He died in 1871.

Cohabitation. See MARRIAGE.

Cohesion depends upon the molecular forces which keep together the parts of bodies, and are insensible at sensible distances. In the case of a small body these forces are much more efficient in keeping the parts together than are the mutual gravitational attractions of the parts. On the other hand, in the case of a large body, such as the earth, gravitation is much more powerful in preventing rupture than cohesion. The term *adhesion* is generally, though quite unnecessarily, used when the cohering particles are dissimilar—as when water clings to glass.

After the parts of a body have been separated, so as to form an incoherent mass, the force of cohesion may be again brought into action by the application of pressure sufficient to force the particles close enough together. Thus two smooth, freshly cut pieces of lead can be made to adhere by slight pressure accompanied by a screwing motion. Also two very smooth slabs of marble adhere, if pressed together, so that considerable force must be exerted to separate them. Barton made a set of cubes with surfaces so true that, if twelve of them were

piled one over the other, the whole series could be lifted by raising the upper one. Lead pencils are made by applying pressure to powdered graphite, so as to make it cohere.

Cohesion Figures. See SURFACE TENSION.

Cohoes, a prosperous manufacturing city of Albany county, New York, on the Hudson, at the mouth of the Mohawk, 3 miles above Troy, and on the Erie Canal. It has six large cotton-mills, and some thirty knitting-mills, besides manufactures of axes, gas-piping, machines, pulp, pins, thread, &c. Pop. (1860) 8799; (1880) 19,416.

Cohort, in the ancient Roman armies, was a portion of a legion, consisting usually of 600 men. Generally, there were ten cohorts to a Legion (q.v.).

Coif (Fr. *coiffe*, Ital. *cuffia*, 'a cap'), a covering for the head in general, but more especially the close-fitting cap of white lawn or silk, originally worn by Serjeants-at-law (q.v.). Like the Biretta (q.v.), it always represented distinct rank and dignity. Its use on all professional and official occasions was both an obligation and a privilege. Later it was the custom to wear a small skull-cap of black silk or velvet over the white coif; and in the beginning of the 18th century, when the fashion of powdered wigs in lieu of natural hair invaded the law-courts, in order that the badge of the order might not be concealed, the perquiers contrived a small round patch of black silk edged with white, to be worn on the crown of the wig. The notion that the coif was a device merely to conceal the tonsure of the monkish lawyers rests only on a loose conjecture of the commentator Spelman, and, though carelessly fostered by Lord Campbell, may be consigned to the same category as the conceit, preserved in Brand's *Antiquities*, which derives the head-dress from a child's caul worn for luck. See Serjeant Pulling's *Order of the Coif* (1884).

Coimbatore, the capital of a district of Madras Presidency, on the Noyil, 304 miles SW. of Madras by rail. It lies 1437 feet above the sea, is well built and drained, and has a cool temperature that renders it a comparatively suitable residence for Europeans. Pop. (1881) 38,967; pop. of district, 1,657,690.

Coimbra, capital of the Portuguese province of Beira, on a hill above the river Mondego, here crossed by a stone bridge, 135 miles NNE. of Lisbon by rail. Its streets are steep, narrow, and dirty, its manufactures confined chiefly to earthenware and combs, and its interest consists mainly in its historical associations. The place derives its name from the Roman *Conimbria*, traces of which lie to the south; it was held by the Goths, and from them passed to the Moors, from whom it was finally conquered in 1064, by Fernando the Great, aided by the gallant Cid. Coimbra was the capital of Portugal for about two centuries and a half from its erection into a kingdom, in 1139, and many of the early kings are buried in and around the old town. Of the public buildings, the most noteworthy are the older of the two cathedrals, the church of San Salvador, and the ruined convent of Santa Clara; across the river is the *Quinta das Lagrimas* ('House of Tears'), where Inez de Castro (q.v.) was murdered. The university of Coimbra, the only one in Portugal, was originally established at Lisbon in 1288, but was permanently transferred here in 1537. It has five faculties and some 900 students, and is still held in repute; attached to it are a museum, an observatory, a botanical garden, and a library of 60,000 volumes. Pop. 13,369.

Coína, a town of Spain, 20 miles WSW. of Malaga, with marble-quarries. Pop. 10,065.

Coining. The privilege of coining money being an exclusive prerogative of the crown, the crime of counterfeiting the king's money, as it was called, was declared to be treason, both by the common law of England and by many statutes. In Scotland, there continued to be some differences in regard to this crime, even after the Union had extended the treason laws of England to that kingdom, and prosecutions were in use to be laid at common law. That practice is now abandoned, and the laws of the two countries were assimilated by a series of statutes, which are codified in the Act of 1861 passed to consolidate the law relating to offences against the coin. All such offences are now prosecuted under this statute. By this act it is a high crime and offence, punishable by penal servitude for life, to counterfeit gold or silver coin; or to colour coin or metal with intent to make it pass for genuine gold or silver coin; or to buy, sell, or import counterfeit gold or silver coin; or unlawfully to make, mend, buy, sell, or possess instruments used in fabricating gold or silver coin; or to convey such instruments out of the mint. To impair or diminish or lighten gold or silver coin (as by clipping or sweating) is punishable with fourteen years. It is an offence punishable with penal servitude for seven years to unlawfully possess gold or silver taken from any coin; or to counterfeit copper coin; or unlawfully to make, mend, buy, sell, or possess instruments for counterfeiting copper coin; or to deal in base British copper coin; or to utter or import base foreign gold or silver coin. Several offences of a less heinous nature are dealt with in the act. In order to bring these offences within the limits of the statute, it is not necessary that the resemblance of the false to the true coin shall be very perfect; but if it be not such as to deceive a person of ordinary observation, the attempt to bring it into circulation is fraud, and not uttering. For false bank-notes, see **FORGERY**.

In the United States, the crime of counterfeiting coin or money is punishable with fine and imprisonment at hard labour for a term of from two to ten years; and includes falsely making, forging, or counterfeiting coins or notes, postal money orders, postal cards, government stamps of all kinds, and government securities, as also importing, possessing, uttering, or passing false coins or notes with fraudulent intent. Mutilating and debasing the coin is also counterfeiting, but is not so severely punished as the making of counterfeit coins.

For coinage and coins, see **MINT, NUMISMATICS, MONEY, BULLION, CURRENCY**.

Coir, or **COCOA-NUT FIBRE**, is the fibre of the husk of the cocoa-nut. The husks are steeped in water, in pits, for six months, or even for a year, and then beaten with a stick till the fibre readily separates. The material is largely used on account of its strength and wear-resisting qualities for floor-matting in positions where there is much traffic, and for making hall and door mats. It is also in demand for coarse brushes, for ships' fenders, and, to some extent, for ropes and cables. In the South Sea Islands, ropes of coir fibre, made by the natives, are extensively used. Coir rope, on account of its lightness, possesses some advantages for maritime purposes. The *Chamærops* (q.v.) is sometimes called the coir-palm.

Coire (Ital. *Coira*; local Romansch, *Quera*; ancient *Curia Rhetorum*; Ger. *Chur*), a town of Switzerland, capital of the Grisons, in the valley of the Upper Rhine, lies in a fertile plain 1940 feet above the sea, and surrounded by high mountains. It is 80 miles S.E. of Zurich by rail, and stands on the Plessur, a mile and a half from its junction with the Rhine. It is of importance as standing on the great road to Italy by the Splügen

Pass, and thus possessing a considerable transit trade. The bishop's palace, and the quarter around it, inhabited by 2400 Catholics, occupy the summit of an eminence, and are separated from the rest by walls and battlements, closed by double gates. Here stands the old cathedral of St Lucius—a Romanesque edifice dating from the 8th century. It contains singular old carving, paintings by Cranach, Holbein, and Dürer, and also, it is said, the bones of St Lucius, a legendary British king. The town-hall, the Rhaetian museum, and two Protestant churches are in the lower town. Romansch is still spoken in the vicinity. Coire is a great tourist centre; and wine, fruit, and corn are produced by the country round. Pop. (1880) 8889.

Coix. See **JOB'S TEARS**.

Cojutepeque, a town of San Salvador, Central America, 15 miles E. of the capital. Pop. 4154.

Coke is a form of fuel obtained by the heating of coal in confined spaces whereby its more volatile constituents are driven off. Caking coal is the most suitable for the manufacture of coke, which, in its principal qualities, is approached by the hard anthracitic coals. The process of coking is conducted (1) in heaps or mounds, or (2) in ovens; but coke is also produced in gas retorts, where, however, it is merely a secondary product. Coking in mounds—a method now little practised—is done in a way similar to that employed for preparing charcoal from wood. The coal is built up into round stacks, around a wide open chimney or column, the larger masses being placed in the centre, and small broken coal outside, the whole being covered with wet coke-dust, except at certain air-holes. The mound of coal is ignited from above, and burns gradually downwards and outwards, giving off at first much smoke and vapour, which consist mainly of tar-water and coal-gas. When the fire ceases to be smoky, the process of coking is concluded, all openings are covered over to exclude air and extinguish combustion, and cooling of the mound is aided by drenching it with water. The principle of making coke in coke-ovens is the same, but the process is much quicker and more economical, and the resulting coke is better in quality than that made in mounds. Formerly the heat and volatile gases given off in coking were allowed freely to escape, but in modern coke-ovens arrangements are made for utilising the combustion in one retort to force the heat of another, by passing the hot gases in flues around contiguous ovens. The whole of the gases pass from these flues into a common flue, by which they are carried away to heat steam-boilers. In a similar way the coal-gas is, from certain kinds of ovens, collected and burned, and the tar-water evolved is condensed and used as a source of ammonia and gas-tar products.

Coke is a hard, brittle, porous solid, with a steel-gray, somewhat metallic lustre, and it does not soil the fingers when being handled. It is principally valued for the intense heat which it gives off in combustion, for its freedom from smoke in burning, and because it does not become pasty and adhesive in the fire. The process of coking also drives off a good deal of the sulphur which may be present in coal, and all these properties render coke a most valuable fuel for many metallurgical operations, and for use where intense smokeless combustion is a desideratum. The higher the temperature to which coal in coking is submitted, the harder and more valuable is the resulting coke, and the heat it gives off is relatively more intense. In chemical constitution coke consists of a modified form of graphite contaminated with earthy impurities from the ash

present in coal. Coal yields by weight about 70 per cent. of coke, which, however, increases in volume in the process of coking by about one-fourth. Coke will absorb about 30 per cent. of moisture from the air, a circumstance which should be borne in mind in its purchase and its use, for such moisture in being driven off greatly reduces the calorific value of the substance.

Coke, SIR EDWARD, jurist, was born of a good old Norfolk family, at Mileham, 1st February 1552. From Norwich grammar-school he passed in 1567 to Trinity College, Cambridge, in 1571 to Clifford's Inn, in 1572 to the Inner Temple; and he was called to the bar in 1578. His rise was rapid—from recorder of Coventry (1585) to member for Aldborough (1589), Solicitor-general (1592), Speaker of the House of Commons (1593), Attorney-general (1594), Chief-justice of the Common Pleas (1606), Chief-justice of the King's Bench and privy-councillor (1613). Meanwhile he had married twice, first, in 1582, Bridget Paston, who brought him £30,000, and died 27th June 1598; next, nineteen weeks later, Lady Elizabeth Hatton, the granddaughter of his patron, Lord Burghley. The rancour shown by him in the prosecutions of Essex and Southampton, Raleigh, and the Gunpowder conspirators (1600–3–5) has gained him little credit with posterity; but from 1606 he stands forth as a vindicator of the national liberties, opposing, unlike Bacon, every illegal encroachment on the part of both church and crown. He dared to cite Bracton's words to James's face, that 'the king should be subject not to man, but to God and the law'; alone of twelve judges, he resisted the royal prerogative; and in the Overbury case he showed an indiscreet zeal to come at the real truth. His removal from the bench on most trivial grounds (November 1617) was aggravated by a quarrel with his wife; and though ten months afterwards he was recalled to the council, his conduct in parliament from 1620 as a leader of the popular party, an opponent of Spain and of monopolies, estranged him for ever from the court party. In 1621–22 he suffered nine months' durance in the Tower; still, old though he was, he carried his opposition into the next reign, the Petition of Right (1628) being largely his doing. He died at Stoke Poges, 3d September 1634, and was buried at Tittleshall in his native county.

Coke was a great lawyer, withal an honest lover of legality, but too bitter and narrow-minded to be really a great man. His four *Institutes* (1628–44) deal with tenures, statutes, criminal law, and the jurisdiction of the several law-courts. The first of these, and most famous, which in 1832 reached a 19th edition, is the so-called *Coke upon Littleton* (q.v.)—a commentary that, in spite of its puerile etymologies, has still a real, if mainly historical, value. Eleven of the thirteen parts of his epoch-making Law Reports were published during his lifetime (1600–15); and the whole, translated out of the original French and Latin, fills 6 vols. in Thomas and Fraser's edition (1826). Mr G. P. Macdonell mentions six minor works in his able and exhaustive article on Coke in the *Dictionary of National Biography* (vol. xi. 1887). See also the Lives by Serjeant Woolrych (1826) and W. Johnson (2 vols. 1837).

Coke, THOMAS, Methodist bishop, born at Brecon in 1747, graduated in 1768 at Oxford, from which university he received the degree of D.C.L. in 1775. He settled as a curate in Somersetshire, but a course of open-air preaching and cottage services, initiated after his introduction to John Wesley in 1776, brought about his dismissal by his rector, and he joined the Methodists, by whom he was attached to the London circuit. In 1782 he

became first president of the Irish conference, and he was elected president of the English conference in 1797 and 1805. In 1784 he was set apart by Wesley as 'superintendent' of the societies in America, to which country he made nine voyages, the last in 1803, and where his outspoken opposition to slavery aroused much hostility; in 1787 he induced the American conference to alter his title to that of bishop. In 1784 Coke had drawn up the first plan of the Methodist foreign missions, and to this cause he devoted the later years of his life with untiring zeal and skill, retaining to the last the direct control of the system he had created. He died in the Indian Ocean on a missionary voyage to Ceylon, 3d May 1814. He published, besides religious works, extracts from his *American Journals* (1790), a *History of the West Indies* (3 vols. 1808–11), and, with Henry Moore, a *Life of Wesley* (1792), intended to forestall Whitehead's labours, with whom the two others, being joint literary executors, had disagreed.

Col (Fr., 'neck'), in Geography, is a depression or pass in a mountain-range. In those parts of the Alps where the French language prevails, the passes are usually named cols—as the Col de Balme, the Col du Géant, &c.

Cola Nut. See KOLA NUT.

Colard, MANSION, the first printer of Bruges, was of French extraction. He published twenty-one works, all in French, save one Latin one; and died in 1484.

Colberg, or KOLBERG, a seaport and watering-place of Prussia, in the province of Pomerania, on the Persante, near its mouth in the Baltic, 170 miles NNE. of Berlin by rail. It stands on a hill, surrounded with three suburbs. The principal church dates from 1316. In 1102 Duke Boleslaus of Poland vainly besieged Colberg, which endured long sieges in the Thirty Years' War, in the Seven Years' War, and again in 1807, when it was most gallantly defended against the French. Colberg has manufactures of woollens, agricultural machines, and spirits; and salmon and lamprey fisheries. Pop. (1885) 16,557.

Colbert, JEAN BAPTISTE, one of the greatest French statesmen, was born at Rheims in 1619. Before he was twenty years of age he obtained a post in the War Office under Le Tellier, and at once began a very successful career. In 1651 he entered the service of the great minister Mazarin, who soon employed him in most important affairs of state. On his death-bed Mazarin warmly recommended Colbert to Louis XIV. 'I owe you everything,' Mazarin is reported to have said to the king, 'but I pay my debt to your majesty in giving you Colbert.' It was in 1661 that Colbert became the chief-minister of Louis XIV. He found the finances in a ruinous condition, and immediately began his reforms. Fouquet, the superintendent under Mazarin, was found guilty of impoverishing the state by his maladministration, and imprisoned for life. The farmers of the state-revenues were forced to yield up the resources of the crown of which they had fraudulently possessed themselves. The debts of the state Colbert reduced by arbitrary composition. In all the departments of finance he introduced order and economy as far as he could. So complete and thorough was the change which Colbert effected, that in ten years the annual revenue had risen to 104 million livres, of which 27 were spent in collection and administration; whereas, when the management of the finances was intrusted to him, the revenue amounted to only 84 million livres, and 52 millions were absorbed in its collection. The financial reforms of Colbert, however, only served as a

basis for a thorough reorganisation of the entire administration. He took measures to improve agriculture. Commerce was extended, roads and canals—including that of Languedoc—were made. In every way he sought to apply the protective system then in vogue to promote the industries of France. He organised anew the colonies in Canada, Martinique, and St Domingo, and founded others at Cayenne and Madagascar. He found France with a few old rotten ships, and in a few years had provided her with one of the strongest fleets in the world, with well-equipped arsenals and a splendid body of seamen. Colbert improved the civil code, introduced a marine code of laws, and drew up the so-called *Code Noir* for the colonies.

While attending to material interests, he did not neglect the arts and sciences; all men of learning and genius found in Colbert a generous patron. The Academies of Inscriptions, Science, and Architecture were founded by him. In short, Colbert was the patron of industry, commerce, art, science, and literature—the founder of a new epoch in France. His aim was to raise the strength of France by developing every side of the national life. In this he entirely succeeded during the early part of the reign of Louis XIV., but his work was not destined to last; the wars of Louis and the extravagance of his court undid all that had been accomplished by Colbert. The rigorous order and precise rules which he established might be beneficial in such hands as his own, but when abused by a selfish or incompetent despotism, could only have the most mischievous results. Colbert died in 1683, bitterly disappointed at seeing the failure of his plans for the regeneration of France. The people were so enraged with the oppressive taxes, for which they blamed him, that his corpse had to be removed from his house by night in order to avoid their fury. Colbert had indeed carried out many measures that were arbitrary and oppressive. He had served a despotic king, who posed as the representative of all that was fair and beautiful in the government, and left the disagreeable tasks of administration to his ministers. See his *Lettres, Instructions et Mémoires* (8 vols. 1802–82), and his *Life* by Clément (2 vols. 1874), Neymarck (1877), and Gourdauld (6th ed. Tours, 1885).

Colburn, ZERAH, a mathematical prodigy, born in Vermont, U.S., in 1804, displayed such remarkable powers of calculation that in 1810 his father left Vermont to exhibit him. At this period he answered correctly such questions as 'How many hours in 1811 years?' in twenty seconds; and a few years later much more complicated problems were solved with equal rapidity. He was shown in Great Britain, and for some time in Paris; from 1816 to 1819 he studied at Westminster School at the expense of the Earl of Bristol. His father died in 1824, and he returned to America; here he was a Methodist preacher for nine years, and from 1835 professor of Languages in Norwich University, Vermont, where he died 2d March 1840. His remarkable faculty disappeared as he grew to manhood.

Colchester, an ancient municipal and parliamentary borough in the NE. of Essex, on the right bank of the Colne, 51 miles NE. of London, and 12 miles from the sea. It is built on the ridge and sides of a promontory, with a port on the river at a suburb called the Hythe, which has a quay for vessels of 150 tons. It is a town of special historical and antiquarian interest. Before the Roman conquest of the island it was the British 'Royal Town' of *Cunobelin* (the *Cymbeline* of Shakespeare); and when the Emperor Claudius

had conquered the south-eastern part of the island, he founded a *colonia* here—the first Roman town in Britain. There are still many remains of that town. The walls are the most perfect Roman walls in England. Immense quantities of pavements, coins, pottery, and other remains of domestic use and personal adornment have been found here. A large cemetery along the principal road out of the town has been carefully explored, and a valuable collection of sepulchral remains found, many of which are in the town museum. The tower of Holy Trinity Church has all the characteristics of Saxon architecture. The castle is the largest Norman keep in England. In the Norman west front of St Botolph's Priory the Roman bricks are a striking feature; and all the old churches have an intermixture of Roman brick in their walls. The Domesday Survey is very full, and gives a complete census of the people. Two taxations of the beginning of the 13th century give not only a complete census of the inhabitants, but also an inventory of their domestic furniture and stock-in-trade, and present a complete view of an English borough of the period. The Protestant refugees from the Low Countries at the end of the 16th century introduced the *bay and say* (baize and serge) trade, which became an important manufacture, and spread into the neighbouring towns and villages. Colchester was one of the eight 'Dutch Congregations' incorporated by royal license. The wars with Spain in the reign of Queen Anne closed the markets for these goods, and the trade died out. The only important historical event of later times was the siege of Colchester, one of the last events of the Civil War between Charles I. and the parliament. The royalists of Essex and Kent under Goring took possession of the town, and were besieged by Fairfax and the parliamentary army from the middle of June 1648 till the middle of August, when the town, starved out, surrendered, and the execution of Sir Charles Lucas and Sir George Lisle, by sentence of court-martial, created a great sensation.

The chief cause of the prosperity of the town throughout its history has been that it was the principal town and natural market of an extensive and fertile corn-growing district, inclosed on three sides by the rivers and the sea. It was during the great continental wars of the beginning of this century, and has again in later times become, a large military depot; and the number of troops quartered here, with their officers and their families, have contributed to its prosperity. The fishery of the Colne and its creeks has for centuries been famous for the quality of its oysters, and has been a valuable portion of the property of the corporation, to which it has belonged from, or even before, the Norman Conquest. Though always the most important town in Essex, it has never been the county town, owing probably to its being inconveniently situated too far down in the Essex peninsula. Pop. (1851) 19,443; (1881) 28,395. See the Rev. E. Cutts's *Colchester* ('Historic Towns' series, 1888).

Colchester, CHARLES ABBOT, LORD, Speaker of the House of Commons, was born at Abingdon, Berkshire, 14th October 1757. He was educated at Westminster School (1763–75) and Christ Church College, Oxford, and in 1779 entered the Middle Temple. In 1792 his practice was bringing him £1500 per annum; and two years later he received the post, worth £2700, of clerk of the rules in the Court of King's Bench. Returned to parliament as a strong Tory in 1795, he effected in his first session an improvement in the legislation regarding temporary and expiring laws; and it is due to his exertions that municipal bodies receive a copy of all new acts as soon as they are printed. The country

is mainly indebted to him for the Private Bill Office and for the royal record commission, whose proceedings he for many years superintended. But his greatest service was in the Act (1800) for taking the first census. In 1802 he was elected Speaker, the duties of which high and honourable office he continued to discharge with as much impartiality as distinction until May 1817, when ill-health compelled him to resign. He received a pension of £4000 a year, and was raised to the peerage as Baron Colchester, his father having been rector of All Saints, Colchester. He died 7th May 1829. See his *Diary and Correspondence* (3 vols. 1861), edited by his son Charles, second Lord Colchester (1798-1867), who was postmaster-general in 1858.

Colchicum, a genus of Liliaceæ, sub-order Melanthaceæ. The species, which are few in number, are stemless, with flowers half subterranean like the crocus, the limb of the perianth and

Meadow Saffron
(*Colchicum autumnale*):
a, a leaf.

part of the tube only rising above ground. The flowers much resemble crocus-flowers, but are readily distinguished by having six instead of three stamens, and three styles instead of one. The superior ovary does not remain to ripen underground, but after the flowering is over, rises in the form of three little follicles slightly adhering to each other, on a lengthened stalk. The only British species is *C. autumnale*, the Meadow Saffron, sometimes also, but incorrectly, named Autumn Crocus, which is plentiful in meadows and pastures in some parts of England and of the continent of Europe. The flowers are pale purple; they appear in autumn, unaccompanied by any leaves; the leaves, which are large and broadly lanceolate, appear in spring, when the stalk which bears the ripening fruit arises amongst them. The whole plant

is very acrid and poisonous, chiefly owing to the presence of an alkaloid called *Colchicine* or *Colchicia*. Cattle are not unfrequently injured by it in pastures where it abounds. It is a valuable medicinal plant, and is administered, in small doses, to allay the pain of gout and rheumatism. Repeated doses produce vomiting, purging, increase of the urinary secretion, and profuse perspiration. The parts chiefly used for medicinal purposes are the corn (popularly called the root) and the seeds. The seeds are round, brown, rather larger than mustard-seed. Other species of colchicum appear to possess similar properties. The *hermodactyls* of the druggists' shops, which for many centuries have enjoyed an extensive celebrity for soothing pains in the joints, and are brought from the Levant, are believed to be the corms either of *C. variegatum* or *C. bulbocodioides*. *C. autumnale* is not unfrequent in flower-borders, particularly a variety with double flowers.

Colchis, a province of ancient Asia, on the east coast of the Pontus Euxinus or Black Sea, situated north of Armenia and south of the Caucasus. Colchis was famous in Greek mythology as the land of Medea (q.v.) and the goal of the Argonauts (q.v.); afterwards it was better known to the Greeks as the seat of some colonies of the Milesians. It was noted for its wines and fruits. The principal town was Dioscurias; the principal river the Phasis. The Colchians were at one time subject to Persia, and subsequently to Mithridates, king of Pontus, and ultimately passed under the mighty empire of Rome.

Colcothar is the name given by the alchemists to the red powder (mainly red oxide of iron) which remains in the retorts when green vitriol or the sulphate of iron is calcined. It is used for polishing glass and the like, and is called crocus by artists.

Cold is the term by which we signify a relative want of sensible heat. There are therefore no determinate boundaries between cold and heat, and it is a mere arbitrary distinction to call the degrees of the thermometer below the freezing-point degrees of cold. When the atmosphere, or any substance which comes in contact with our body, is at a lower temperature than the skin, it absorbs heat from it, and we call it cold. See HEAT.

The physiological action of cold on the animal organism requires a brief notice. All animals (the warm-blooded animals to the greatest extent) have a certain power of maintaining the heat of the body, in defiance of external cold, as has been shown in the article ANIMAL HEAT. This power is mainly due to a process analogous to combustion, in which carbon and hydrogen taken into the system in food are made to unite with oxygen derived from the air by respiration. If the combustible materials are not duly furnished, or if the supply of oxygen be deficient (as in various diseased conditions), there must be a depression of temperature. Now, if the temperature of a bird or mammal (except in the case of hibernating animals) be lowered about 30° below its normal standard (which in birds ranges from 100° to 112°, and in mammals from 96° to 102°), the death of the animal is the result. The symptoms indicating that an animal or a man is suffering from a depression of the temperature of the body are—retardation of the circulation of the blood, causing lividity of the skin, which is followed by pallor, in consequence of the blood being almost entirely driven from the surface through the contraction of the vessels; a peculiar torpor of the muscular and nervous systems at the same time manifests itself in an indisposition to make any effort or exertion, and in intense sleepiness. The respiratory movements become slower (see RESPIRATION), and the loss of heat goes on, therefore, with increasing rapidity, till the fatal limit is reached, and death supervenes.

In hibernating animals (the marmot, dormouse, bat, &c.) the power of generating heat within their own bodies is very slight, their temperature following that of the external air, so that it may be brought down nearly to the freezing-point. See the articles HIBERNATION, STARVATION, DORMANT VITALITY; also, for other phenomena connected with cold, HEAT, CLIMATE, FREEZING, ICE, THERMOMETER, TEMPERATURE.

Great or prolonged atmospheric cold is a most powerful depressing agent, and is a fruitful cause of disease and even of death. Whenever the temperature of the atmosphere is suddenly reduced, and particularly when it is reduced below the freezing-point, a considerable addition takes place to the mortality of the country at large. The

effects of cold are, in ordinary circumstances, most apparent among the aged and the very young, and among those suffering from chronic disease; but when a very low temperature is long continued, even the healthy are sure to suffer, when impoverished so as not to have sufficient means of external warmth in their homes. The most direct effects of cold are in the production of what is commonly called Frost-bite (q.v.).

Cold is applied in various ways in the treatment of disease. In some forms of fever, a cold bath, or cold wet pack, is the best means of reducing a very high temperature which of itself threatens life. In many inflammations relief is best obtained by the local application of ice, or of a coiled tube through which cold water circulates. The tonic and stimulating effects of a temporary application of cold are familiar in the cold morning bath, or the use of cold water sprinkled on the face of a person who has fainted. The disease commonly termed a 'cold' has been already described under CATARRH.

Cold Cream is the term applied to an ointment containing rose-water which is used as a mild and cooling dressing for the skin. It may be prepared by melting together almond-oil five parts, spermaceti one part, and white wax one part. Three parts of rose-water are then added with brisk stirring, which is continued till the whole is cool, and of a soft creamy consistence. As cold cream prepared in this way is liable to turn rancid, glycerine is sometimes added, or the almond-oil is replaced by white vaseline. Cold cream is a pleasant application to irritated surfaces, protecting them from the influences of the weather, and promoting the healing of wounds and chapped hands.

Coldstream, a town of Berwickshire, 15 miles SW. of Berwick by rail, on the Tweed, over which there is a fine bridge by Smeaton (1766). At Coldstream was the famous ford by which Edward I. entered Scotland in 1296, and near which he met the Scottish nobles, to settle the dispute about the crown of Scotland. By this ford also the Scots invaded England in 1640. Being convenient as a border town, Coldstream, like Gretna Green and Lamberton toll-bar near Berwick, was formerly celebrated for its clandestine marriages. Pop. 1616.

Coldstream Guards, a regiment in the Foot Guards (q.v.) or Household Brigade, the oldest in the British army except the 1st Foot, now called the Royal Scots. Raised in 1660 by General Monk at Coldstream, it was at first called 'Monk's Regiment'; but when parliament consented to give a brigade of guards to Charles II., this corps, under the name of Coldstream Guards, was included in it.

Coldwater, capital of Branch county, Michigan, 156 miles E. of Chicago, on the Lake Shore Railway, has several foundries, flour-mills, and manufactories, and a public school which cost \$100,000. Pop. (1880) 4681.

Cole, SIR HENRY, was born at Bath, 15th July 1808, educated at Christ's Hospital, and became assistant-keeper of the Records in 1838. He wrote much for the newspapers and reviews, and under the name of 'Felix Summerly' produced about twenty children's books. He was chairman of the Society of Arts, did valuable service on the committee of the Great Exhibition of 1851, was the founder of the South Kensington Museum, and in 1860 became its director. For his services on innumerable committees and councils, and in promoting valuable reforms, he was made K.C.B. in 1875; and he held several foreign decorations. He died 18th April 1882. See his Autobiography (2 vols. 1884).

Cole, THOMAS, painter, born at Bolton-le-Moors in 1801, removed to America in 1819, where he became one of the best-known landscape-painters. In 1830 two of his pictures appeared in the Royal Academy, and he afterwards made sketching tours through England, France, and Italy; but all his best landscapes were American, and these, as well as his allegorical subjects, are highly valued. He died 11th February 1848.

Cole, VICAT, landscape-painter, was born at Plymouth in 1833, and since 1853 has been a frequent contributor to the Royal Academy exhibitions. In 1870 he became A.R.A., and in 1880 R.A. Very many of his paintings are Surrey scenes.

Colebrooke, HENRY THOMAS, the pioneer of Sanskrit scholarship in Europe, was born in London, 15th June 1765, the son of Sir George Colebrooke, banker, and eventually chairman of the board of directors of the East India Company. He was educated at home, and early showed a strong disposition for mathematical studies. In 1782 his father's influence procured him a writership in the Bengal service. He was a voracious reader, and his alert mind found its relaxation in the change from administrative to scientific labour. His duties as revenue officer at Tirhut led him to make a minute study of the state of husbandry in Bengal, and his Remarks thereon (Calcutta, 1795, privately printed) formed so searching a criticism of the existing policy that the work could not be published in England. At Purneah his legal functions led him to study Indian law and learn Sanskrit; and he began in 1794 publishing essays on Indian religion, poetry, and science in the *Asiatic Researches* of the recently founded Asiatic Society of Calcutta. His removal in 1795 to the magistracy of Mirzapur gave him the opportunity of cultivating the acquaintance of the learned men of the neighbouring Sanskrit college at Benares, and with this advantage he brought out his *Digest of Hindu Law on Contracts and Successions* (translated from the Sanskrit, 1798, 4 vols. Calcutta). A mission to Nagpur (1799-1801) interrupted his work, and on his return he was appointed a judge of the new court of appeal at Calcutta, and at the same time honorary professor of Hindu Law and Sanskrit at the college of Fort William. Yet he contrived during this busy period to publish the first (and only) volume of his *Sanskrit Grammar* (1805), based upon Pāṇini and the native commentators, to write his famous articles on the Vedas and on the sect of Jains, besides many other valuable essays for *Asiatic Researches*, and also to supplement his *Digest* by *Two Treatises on the Hindu Law of Inheritance* (1810). Before this he had reached the eminence of a seat on the governor-general's council (1807), and was using his influence earnestly in the direction of administrative reform and the encouragement of oriental studies. He retired in 1814, and devoted himself to scholarly work in England, especially to eastern science. Several of his essays in *Asiatic Researches* related to Hindu astronomy, meteorology, mathematics, geology, and botany. He contributed also to the *Transactions of the Astronomical Society*, to *The Quarterly Journal of Science*, the Linnean and the Geological Societies, as well as, more especially, to the Royal Asiatic Society, which he helped to found in 1823. His last years were troubled by care, blindness, and much bodily suffering, endured with fortitude; and on 10th March 1837 he died at the age of seventy-two. His translation of the *Saṅkhyā Kārika* was posthumously edited by Professor H. H. Wilson. His work as a Sanskrit scholar possessed the highest merits of extreme conscientiousness and caution, scientific accuracy, and a stern repression of the tendency to fanciful exaggeration which marked the early theories of European

scholars on Indian science and religion. His life has been well written by his son, Sir T. E. Colebrooke (1873), and his immense services to Sanskrit scholarship are lucidly criticised in Max Müller's *Biographical Essays* (1884).

Colenso, JOHN WILLIAM, D.D., Bishop of Natal, the son of a Cornish gentleman, was born at St Austell, January 24, 1814. He was educated at St John's College, Cambridge, where he graduated as second wrangler in 1836, and became fellow and assistant-tutor of his college. From 1838 to 1842 he was an assistant-master at Harrow, and for the next four years a tutor at Cambridge. Appointed, in 1846, rector of Fornett St Mary, Norfolk, he published *Miscellaneous Examples in Algebra* in 1848, *Plane Trigonometry* in 1851, and *Village Sermons* in 1853, in which same year he was appointed first Bishop of Natal. With that energy of character which always distinguished him, Dr Colenso at once began a close study of the natives and of the Zulu language, and after a time prepared a grammar and dictionary, and made a translation of the English Prayer-book and a portion of the Bible, printing them in his own house. In 1860 he memorialised the Archbishop of Canterbury against compelling those natives who had already more than one wife to renounce polygamy as a condition to baptism, alleging that he could find no warrant for such compulsion either in the gospel or in the ancient church. In 1861 he published his *Translation of St Paul's Epistle to the Romans, commented on from a Missionary Point of View*, in which he objected to the doctrine of eternal punishment. He next announced that he had become convinced of the improbability of many statements of facts and numbers in the historical books of the Bible; and in 1862 there appeared the first part of his work on *The Pentateuch and the Book of Joshua Critically Examined*. This treatise brought down upon its writer an avalanche of criticism and remonstrance. He had called in question the historical accuracy and Mosaic authorship of the books cited, and his work was condemned as heretical by small majorities in both Houses of Convocation of the province of Canterbury. The bishop was entreated to resign his see by his episcopal brethren, some of whom inhibited him from preaching in their dioceses. The second part of his work appeared in 1863. Convocation censured him in the succeeding year, and he was declared to be deposed from his see by his Metropolitan, Bishop Gray of Capetown. He appealed from this judgment in 1865, when the Privy-council declared the deposition to be 'null and void in law.' The bishops constituting the council of the Colonial Bishops Fund, however, refused to pay him his income, upon which he appealed to the Court of Chancery. On October 6, 1866, the Master of the Rolls delivered an elaborate judgment, ordering the payment of the bishop's income, with all arrears and interest, unless his accusers should bring him to trial for heresy; but this they declined to do. Immediately before Dr Colenso's return to his diocese in August 1865, his English friends presented him with £3300 as a testimonial. The Anglican community at the Cape was now divided into two camps, and although Dr Colenso remained the only bishop of the Church of England in Natal, Bishop Gray publicly excommunicated him, and in 1869 consecrated Dr W. K. Macrorie as Bishop of Maritzburg, his authority practically extending over the same diocese. In 1874 Dr Colenso visited England to report upon the affairs of his diocese to the Archbishop of Canterbury, and to consult with the heads of the church upon its relations to the new see of Maritzburg. While in England he pleaded the cause of Langalibalele,

a dispossessed Zulu chief. On his return to South Africa he warmly espoused the interests of the natives against the oppression of the Boers, and the encroaching policy of the Cape officials. He opposed the attitude of Sir Bartle Frere and the home government during the Zulu war, and earnestly strove to make peace between the contending parties. Owing to his exertions, Cetewayo was allowed to visit England and plead for his rights. Dr Colenso's defence of the aboriginal claims lost him much valuable support; but the bishop and his daughter never swerved from what seemed to them to be the wisest as well as the only honourable course to pursue towards the natives of South Africa. In addition to the works already named, Dr Colenso was the author of *Ten Weeks in Natal* (1855); *The New Bible Commentary Literally Examined* (1871-74); *Lectures on the Pentateuch and the Moabite Stone* (1873); and a volume of *Sermons* (1873). His critical analysis of the Pentateuch extended to seven parts, the last of which appeared in 1879. This work was not without influence in modifying the views of Kuenen and other continental commentators. Bishop Colenso died at Durban, Natal, June 20, 1883. He was a man of upright and inflexible character, yet gentle in demeanour and chivalrous in controversy. His theological works still find many readers, while his treatises on algebra and arithmetic have long been text-books in the public schools and universities. See his Life by Sir G. W. Cox (2 vols. 1888).

Coleoptera. See BEETLE.

Colepeper, JOHN, was a native of Sussex, but, save that he had seen much foreign service, little is known of him till his return for Kent in 1640 to the Long Parliament. There he pursued a course much the same as Hyde's (see CLARENDON), and in January 1642 was created Chancellor of the Exchequer, a twelvemonth later Master of the Rolls, and in 1644 Lord Colepeper. With Hyde he attended Prince Charles to the western counties, and from Jersey he brought him to Henrietta Maria, to whose party he thenceforth attached himself. He lived to see the Restoration, dying on 11th June 1660. He was an able, far-seeing councillor, but rough and unstable.

Coleraine, a seaport in County Londonderry, on the right bank of the Bann, 4 miles from its mouth, 33 by rail N.E. of Londonderry, and 61 N.W. of Belfast. It has manufactures of fine linens, pork-curing, distilling, and important fisheries in the river. The Bann is here spanned by a fine stone bridge, 288 feet long, which connects Coleraine with its suburb on the left bank of the river, Waterside or Killowen. Vessels of 200 tons can discharge at the quay—those of greater burden lie at Portrush, 6½ miles off. Pop. (1861) 6236; (1881) 5899. Until 1885 Coleraine returned a member to parliament.

Coleridge, HARTLEY, eldest son of the great Coleridge, was born, an eight months' child, at Clevedon, Somersetshire, 19th September 1796. Very early he showed uncommon parts, and a singular power of living entirely in a make-believe world of dreams and imagination. Wordsworth's lovely and touching poem to the child at six years of age was strangely and sadly prophetic of his after-life; hardly less the concluding lines of his own father's two poems, *The Nightingale* and *Frost at Midnight*. Hartley was brought up, after the separation of his parents, by Southey at Greta Hall, and was educated chiefly at Ambleside school. In 1815 he went to Oxford as postmaster of Merton College. His scholarship was great but unequal, and not such as to lead to high distinc-

tions in the schools. His failure after no less than three attempts to gain the Newdigate filled him with 'a passionate despondency,' from which he turned for relief to a fatal remedy. When at length he had gained with credit an Oriel fellowship, at the close of his probationary year he was judged to have forfeited it mainly on the ground of intemperance. 'The sentence might be considered severe,' says his brother; 'it could not be said to be unjust.' Unhappily it ruined his life, crushed his spirit, and made recovery impossible. With £300 given him by the college, Hartley spent the next two years in London, then tried for four or five years taking pupils at Ambleside, occasionally writing for *Blackwood's Magazine*, next lived some time at Haslemere, and then went to live at Leeds with one Bingley, a publisher, for whom he agreed to write a biographical work on the worthies of Lancashire and Yorkshire. Of these but thirteen lives had already been written when Bingley failed. These were published under the titles of *Biographia Borealis* (1833) and of *Worthies of Yorkshire and Lancashire* (1836). Bingley also printed a small volume of his poems in 1833. Hartley next returned to Haslemere, the only remaining interruptions to his ordinary life being two short and not unsuccessful intervals of teaching at Sedburgh grammar-school. His father, who died in 1834, made a special provision for him in a codicil to his will, and his mother's death in 1845 made him by an annuity completely independent. He continued to write poetry, and wrote a life of Massinger for an edition projected by Moxon. His days were spent in fitful study, lonely reverie, and wanderings over the Lake Country, with, unhappily, occasional lapses into intemperance. The dalesmen everywhere treated 'Poet Hartley' with a singularly affectionate respect, not without a kind of awe at his *erie* appearance, his abstracted air, his small stature, prematurely white hair, and gentle manners. He loved children and animals, and was fondly loved by them in return. He died 6th January 1849, and was buried beside what was soon to be Wordsworth's grave.

Hartley Coleridge's poetry falls short of the great, but sometimes approaches it, and even nearly. It is graceful, tender, and sincere, pervaded throughout with a charm of a nature rare and almost unique, alternately wise and playful, and often perfect in the expression of the thoughts it has to convey. He is greatest in the sonnet—a form which seems exactly to have been the measure of his powers, or rather of the fitful periods of his poetic passion. *Leonard and Susan*, a narrative poem in blank verse, and *Prometheus*, a dramatic fragment, are the only poems of any length. His *Poems* were collected by his brother Derwent, with a Memoir (2 vols. 1851); also his *Essays and Marginalia* (2 vols. 1851).

Coleridge, LORD. John Duke Coleridge (eldest son of Sir John Taylor Coleridge, the great poet's nephew, and himself the biographer of Keble) was born in 1821, and educated at Eton and Oxford, was called to the bar in 1847, and was for some years leader of the western circuit. Appointed recorder of Portsmouth in 1855, he took silk in 1861, and from 1865 to 1873 represented Exeter in parliament, where he was Solicitor-general (1868) and Attorney-general (1871) under Mr Gladstone. In 1873 he became Chief-justice of the Court of Common Pleas, and Baron Coleridge of Ottery St Mary; and in 1880 he succeeded Sir Alexander Cockburn as Lord Chief-justice of England.

Coleridge, SAMUEL TAYLOR, was born at Ottery St Mary, Devonshire, October 21, 1772, where his father was vicar, and master of the grammar-school. He was the youngest of ten

children of his father's second marriage. A singularly precocious child, he had read the *Arabian Nights* in his fourth year; but he said of himself, 'I never thought as a child.' On his father's death he was sent, in his ninth year, to be educated at Christ's Hospital, where he had Charles Lamb for a school companion. He was poorly fed, and badly taught; but he plunged with eagerness into a whole library of literature, and read Homer and Virgil for the mere pleasure of it. Remaining at Christ's for eight years, he became head of the school, and showed a remarkable capacity for assimilating all sorts of knowledge. He was a mental rover from his boyhood onwards, with a very miscellaneous intellectual appetite. At school he translated the hymns of Synesius, studied works on medicine in Latin, on metaphysics in Greek, and fell in love with the sister of one of his companions. His last years at school, however, were years of suffering. He used to bathe in the New River, plunging into the water with his clothes on, and after a swim, resumed his games, or returned to his books, without changing his garments. The inevitable result was rheumatic fever and other ailments. While at school he had a passing attraction not only to his schoolmate's sister, but to the shoemaker's craft. This was a short-lived fancy; and in October 1791 he passed to Jesus College, Cambridge, a few months after Wordsworth had taken his B.A. degree, and left the university. During his first year at college he did good work in classics, and became one of four selected candidates for the Craven scholarship in 1793; but his bent not being mathematical, and having little chance of winning the chancellor's medal, he gave himself up to general literature. He also became interested in politics, took a strong position on the Liberal side, and won distinction, even thus early, as a marvellous talker. He got into difficulties in Cambridge, through extravagance in furnishing his rooms, became depressed, and in a panic fled to London, where he enlisted in the 15th Dragoons, under the name of Silas Tomkyns Comberbach (a name assumed to conceal and yet reveal his identity as S. T. C.). He never could learn, however, how to manage a horse, never rose out of the awkward squad; and a chance accident disclosing his knowledge of classics, led to his discovery by his friends, and to his being bought out of the service. At the close of the summer term, he went from Cambridge to Oxford; and there, at Balliol College, he for the first time met Southey. In July he took a pedestrian tour in North Wales, after which he went to Bristol, and there again met both with Southey and with Robert Lovell, the latter of whom had just married a Miss Fricker, to whose sister (Edith) Southey had engaged himself. Coleridge at once followed his example, and became engaged to another sister (Sara); and amongst them they formed the Quixotic plan of emigration to the banks of the Susquehanna in America, where they were to form a 'Pantisocracy'—an ideal community on the principles of Communism. Two hours of daily labour were to suffice for providing the necessities of life, the rest of their time being devoted to intellectual work and social converse. They were to have all things in common; and, as a result of the experiment, were to bring in a golden age, for themselves and others. It was a dream; and it passed, as dreams do.

Coleridge had left Cambridge without taking a degree. In the late autumn of 1794 he went up to London, and there renewed his acquaintance with Lamb. But in December he was brought back to Bristol by Southey, who feared he might come under some new fascination in the metropolis. He had to find the means of livelihood, not on the Susquehanna, but in the west of England; and

he began a course of miscellaneous lecturing on literary and political subjects. It was now that he made the acquaintance of Joseph Cottle, the Bristol bookseller, who became so kind a friend. Cottle offered to publish a volume of poems for him, giving him thirty guineas for the copyright; and, vexed at his delay in completing the volume, subsequently offered him a guinea for every hundred lines of verse he would write, after this first volume was printed. With this promise, and what he thought provision for life, he ventured to marry; and in October 1795 Sara Fricker became Mrs Coleridge. They went at once to a small cottage, which is still to be seen at Clevedon in Somerset. Here, however, Coleridge did not long remain. We find him in Bristol in December getting his first volume of poems ready for the press (it was published in April 1796), and at the same time attempting to start a weekly journal to be called the *Watchman*, which was to contain general news, parliamentary reports, literary intelligence, and reviews. In his efforts to float this journal he went north to Birmingham, Manchester, Sheffield, &c., to procure subscribers. He succeeded in starting it, Cottle being the publisher; but it only reached its tenth number, and failed—the generous publisher bearing all the loss. Coleridge next tried the experiment of preaching in the Unitarian chapels around Bristol. Cottle gives an account of his appearance in one of these at Bath on a Sunday, 'in blue coat and white waistcoat,' to discourse on the corn laws and the powder tax. This eccentricity did not last. Another friend, and a somewhat remarkable man—Thomas Poole of Nether Stowey—provided him with a small house and garden in the village of Stowey; and there Coleridge went to live, in January 1797, with his wife and child (whom he had named Hartley, from his admiration for the philosophy of David Hartley). Poole also very generously raised a sum of money to provide an annuity for his friend.

Before this date Coleridge had made the acquaintance of Wordsworth. In the early spring of 1796 Wordsworth went up to Bristol from Racedown in Dorsetshire, to see both Coleridge and Southey; and, in a list of authors with whom he was acquainted, drawn up by Coleridge in March of that year, Wordsworth's name occurs. In the following year Coleridge went down from Stowey to Racedown to return the visit. As late as 1845 Mrs Wordsworth gave a graphic account to Sara Coleridge of her father's 'leaping over a gate, and bounding down a pathless field' on this first visit to Racedown. In July 1797 the Wordsworths moved from Racedown to Alfoxden, partly to be nearer Coleridge; and during that winter—which William and Dorothy Wordsworth spent in Somerset—Coleridge was their almost daily companion, roaming the woods and coombs of the Quantocks with them, or spending the night at Alfoxden. Wordsworth and he discussed together the principles of poetry, and planned a joint volume of verse to illustrate these principles; Wordsworth undertaking to invest commonplace themes with an imaginative interest, by disclosing what underlay them; and Coleridge taking supernatural or romantic incidents, humanising the stories so as to give new life to them. This was the origin of the *Lyrical Ballads*, the little volume which more than any other marked a new departure in poetical literature at the beginning of the present century. To it Coleridge contributed the *Ancient Mariner*. The book was published in 1798.

This meeting of Coleridge and Wordsworth was one of the most remarkable conjunctions of genius in the literary history of England, and the days they spent together in Somerset were perhaps the

most joyous in their lives. While living at Nether Stowey, Coleridge kept up the practice of occasional preaching; and 'to prevent the necessity of his going into the ministry,' another admiring friend, Josiah Wedgwood, sent him a draft for £100. He returned it to the donor; but, soon afterwards, Coleridge accepted an annuity of £150 from the brothers Wedgwood, given to him on the condition that he would devote his life wholly to poetry and philosophy. In 1798, he started with the Wordsworths for Germany, crossing from Yarmouth to Hamburg; and while Wordsworth went to Goslar, Coleridge proceeded to Ratzeburg, to study the language and literature of the country. He moved on to Göttingen in January 1799. An interesting picture of his life in Germany is given in *Satyrane's Letters*. He returned to England in June; in August we find him at Stowey; and in September in Yorkshire with the Wordsworths. They had some idea of settling together, to renew the fellowship of the Quantock days. On the approach of winter, however, Coleridge went up to London, and there translated *Wallenstein*, one of the best bits of work he ever did. He now made fresh attempts at journalism, and wrote both prose and verse for the *Morning Post*; but, while some of his articles were admirable, he was such an irregular contributor, that his connection with the *Post* lasted only for a few months. In July he went north to Keswick, and took up his residence at Greta Hall, which Southey also made his home in 1803. At Keswick he continued his poetic work, and wrote the second part of *Christabel*. The Wordsworths had now been settled for some time at Dove Cottage, Grasmere, and there Coleridge was their frequent guest. Dorothy Wordsworth's Grasmere journal (as yet in MS.) is full of allusions to his visits, and to the wonderful friendship of these days—a friendship immortalised in her brother's *Stanzas written in a pocket copy of Thomson's Castle of Indolence*. But during the years he spent at Keswick, Coleridge came under the influence of what was henceforward to be the very curse of his life. His health had never been robust; rheumatism and neuralgia had tortured him; and, becoming his own doctor, he had recourse to the anodyne of opium. Little by little the habit grew, and the 'Kendal black drop' at length enslaved him. It injured his constitution and killed his imagination; it enfeebled his will and destroyed his sense of truth and honour. Few things in literature are so pathetic as his own lament over the deterioration of his nature, in his *Dejection, an Ode*. The details of this malady, and what it led to, have not yet been fully told.

Charles Lamb came to visit him at Keswick in 1802. In 1803 he started with the Wordsworths, on their memorable Scottish tour; but left them in a fortnight, and did wonderful feats of walking alone. He now thought of many plans for the recovery of health, which were really but plans to flee from his own shadow. The frugal Wordsworth forced him to accept a loan of £100. He was befriended by others, and he sailed for Malta in April 1804. There he became secretary to the governor, Sir Alexander Ball, an office for which he was entirely unsuited. His letters from abroad were hypochondriacal, valetudinarian, and sad in many ways. From Malta he went to Sicily, to Naples, and to Rome; but he had to leave Italy with some abruptness, an order, it is said, having been issued by Napoleon for his arrest, on the ground of some republican utterances years before; and the vessel in which he sailed being chased by a French cruiser, he threw all his papers (which included many of Wordsworth's poems) overboard. In August 1806 he returned to England. It is unnecessary to trace his subsequent wanderings to and fro, from

London to Keswick, to Penrith, to Coleorton, to Bristol, and to Bridgwater. At London he began what might have been a very remarkable series of lectures at the Royal Institution; but the experiment failed, from the same cause that previous ones had failed. He next thought of a fresh venture in journalism, and projected a new weekly paper, *The Friend*, for which he got a number of subscribers. It was printed at Penrith at his own expense. The Wordsworths took him into their house at Allan Bank, Grasmere, for the winter; and while Coleridge wrote most of the papers for *The Friend* himself, Wordsworth supplied him with some of the articles, and Sarah Hutchinson transcribed them week by week for the press. The paper lived from August 1809 to March 1810. The habit of opium-eating, which had now obtained a fatal ascendancy, could not be hidden from his friends; and at this juncture the Wordsworths, with the greatest delicacy, tried their utmost to help and to befriend him. They were misunderstood. He went up to London in 1810, and a strange cloud (the full story of which has yet to be told) obscured for a time the old relationship between the households. A partial estrangement lasted for some years, but was at length overcome by the friendly offices of Henry Crabb Robinson.

During Coleridge's later years in London he lived for four years with an old Bristol friend, John Morgan, at Hammersmith. He first tried the experiment of lecturing on Shakespeare. Occasionally his appearances were brilliant; more usually they were absolute failures. His conversational powers, however, seem to have increased, while his success as a lecturer diminished. All his life he had been in the habit of receiving gifts freely from such friends as the Beaumonts, and the Wedgwoods, from Stuart, and Wordsworth, and De Quincey; and though he occasionally did generous things to others, his neglect of the primal duties to his own family put a severe strain upon the tie that bound these friends to him.

The remaining years of his life were spent at Highgate with Mr and Mrs Gillman, whose kindness and consideration were unbounded. Though a wreck of his former self, the baleful opium-habit lessened, as Coleridge grew older, and he was able to do a good deal of miscellaneous writing. Some of his best prose work was written at Highgate. Though a dreamy and often unintelligible sage, he became a sort of oracle to a circle of enthusiastic admirers that gathered round him, and he completely fascinated the young men, who made their weekly pilgrimages to Gillman's house to hear him talk. As the years went on, his health somewhat improved, and he was even able to make occasional visits. In 1829 he took a short tour with the Wordsworths, accompanying the poet and his daughter to the Rhine. He died on the 23d July 1834, and was buried at Highgate.

As a Poet, Critic, and Philosopher (the three functions having been combined by Coleridge as they had never been by any previous Englishman) he was certainly a star of the first magnitude in the firmament of letters. For originality, insight, grace, musicalness, deft subtlety of thought, naturalness and charm of diction, he had only one rival amongst the poets of the Renaissance. It is true there have been greater poets in England, but there has been no greater poetical critic in British literature. Coleridge was a critic of poets (and the poets have, as a rule, been the best critics of each other). As yet there is no estimate of the literary revival which Coleridge and Wordsworth inaugurated that is superior to what the former wrote in his *Biographia Literaria*; and he was a philosophical critic, because he was a philosopher amongst the poets. He may be said to have inaugurated a new

era by his poetic idealism, and by introducing the spirit of Plato alike into his poetry and his literary criticism. As a philosopher, however, he does not occupy the foremost place. He was too miscellaneous, too assimilative, and his intellect too meteoric and vagrant for speculative originality of the highest order. But he was one of the most suggestive of critics. Though not profoundly learned, he was very widely read; and he did more to leaven English philosophy, literature, and theology with the depth and the free spirit of Germany, than any one of his contemporaries. He vitalised whatever he discussed; and his writings will probably continue to kindle successive generations, and to fascinate them, even while they fail to convince.

Coleridge's most important works are: *Poems* (1876); *Wallenstein* (1800); *The Friend* (1809-10); *Remorse* (1813); *Christabel*, *Kubla Khan*, &c. (1816); *The Statesman's Manual* (1816); *Sibylline Leaves* (1817); *Biographia Literaria* (1817); *Aids to Reflection* (1825). Posthumously published—four volumes of *Literary Remains* (1836-38); *Confessions of an Enquiring Spirit* (1840); *Essay on Method* (1845).

The chief authorities in reference to Coleridge are *Letters, Conversations, and Recollections*, by Allsop (1836); *Cottle's Early Recollections* (1837); *Gillman's Life* (1838); *Coleridge's Letters to Sir George and Lady Beaumont* (1886); *Mrs Sandford's Thomas Poole and his Friends* (1889); the *Biographia Literaria* (1817); De Quincey's 'S. T. Coleridge,' in his *Recollections of the Lakes* (1857); Eliza Meteyard's *Group of Englishmen, 1796-1815* (1871); the *Memoirs of Wordsworth* (1851); Southey's *Life and Correspondence* (1850); *Lamb's Letters* (1888); *Mr Traill's Coleridge* (1884); and *Alois Brandl's S. T. Coleridge and the English Romantic School* (1882). A complete and exhaustive biography was commenced in 1888 by his grandson, Mr Ernest Coleridge.

Coleridge, SARA, the gifted daughter of the great Coleridge, was born, 22d December 1802, at Greta Hall, near Keswick, where she was brought up by Southey. She grew up a remarkably sweet and graceful girl, with already more than a woman's intellect. Her 'depth of meditative eye' is noticed by Wordsworth in the finest lines of his rather poor poem, the *Triad* (1828), the other maidens of the group being Edith Southey and Dora Wordsworth. Sara early showed remarkable powers of mind, with all her father's leaning towards psychology and abstract thought. At twenty she published, to aid her brother Derwent's college expenses, a translation of Martin Dobrizhofer's Latin *Account of the Abipones* (1784), and three years later the 'Loyal Servitor's' memoirs of the Chevalier Bayard. In 1829 she married her cousin, Henry Nelson Coleridge, and on his death in 1843 succeeded him in the task of annotating and editing her father's writings. Her health failed early, and she died 3d May 1852. Her own works were *Pretty Lessons for Good Children* (1834), and *Phantasmion* (1837), a somewhat remarkable fairy-tale. Her *Memoirs and Letters* were edited by her daughter in 1873.—Her son, HERBERT COLERIDGE, born in 1830, was educated at Eton and Balliol College, took a double-first in 1852, and was called to the bar, but devoted himself to the study of comparative philology. Elected a member of the Philological Society in 1857, he threw himself with enthusiasm into its ambitious project of a standard English dictionary, and was practically editor in its earlier stages. His own works were a *Glossarial Index to the Printed English Literature of the Thirteenth Century* (1859), and an excellent essay on King Arthur, printed after his untimely death (at London, 23d April 1861) by the Philological Society.

Coleroon, the largest and most northerly branch from the Kaveri, flows 94 miles, chiefly between Trichinopoly and Tanjore, into the Bay of Bengal. It is remarkable for its two weirs or dams, the *anicuts*, constructed in 1856.

Coles, COWPER PHIPPS, naval architect, born in Hampshire in 1819, early entered the navy, and became lieutenant in 1846 and captain in 1856. In 1855 he constructed a gun-raft, which was favourably reported on; from 1856 he was engaged in experiments, and ultimately produced a form of turret-ship, the general idea of which had probably occurred to him independently, although its development owed much to the invention of Ericsson (q.v.). A vessel was built from his designs, with little more than 6 feet of freeboard; it was commissioned as the *Captain* early in 1870, and on 7th September turned bottom upwards in a gale, and sank off Cape Finisterre, almost all on board, including Coles, being drowned.

Coleseed. See RAPE.

Coleshill, a market-town of Warwickshire, 10 miles ENE. of Birmingham. Pop. of parish, 2356.

Colet, JOHN, born in London about 1467, was the eldest son of a family of twenty-two. His father, Sir Henry Colet, was twice Lord Mayor of London. Colet studied at Oxford with the view of entering the church, and about 1493 made a prolonged visit to the Continent, travelling through France into Italy. While in Italy he became acquainted with the views of Savonarola, which subsequent study and experience led him to regard with increasing approval. Having returned to England in 1496, and been ordained priest, he delivered at Oxford a series of lectures on the Epistles of St Paul, which attracted great attention, his principles of interpretation being at every point opposed to those of the scholastic theologians. In 1498 Erasmus came to Oxford, and it is one of Colet's chief claims to remembrance that he powerfully influenced that scholar's opinions on the proper methods of Scripture interpretation and on the value of the scholastic philosophy. In 1505 Colet was made Dean of St Paul's, London, and in this office still continued to deliver lectures on different books of Scripture, which gave rise to much diversity of opinion. With the large fortune he inherited on the death of his father, Colet founded St Paul's School (q.v.). At this school 153 scholars were received, whose education was conducted in a spirit far in advance of the time. On account of Colet's vigorous denunciation of the ignorance and corruption of the clergy, charges of heresy were brought against him, but Archbishop Warham refused to support them. Colet also spoke out strongly against the French wars of Henry VIII., who, nevertheless, always treated him with regard. In 1518, feeling his end approaching, Colet appointed the Mercers' Company of London as managers of his school—a step of decisive importance, as it was the first example of lay management of an educational institution. He died of dropsy, 16th September 1519.

Of late years it has been conclusively shown that Colet was one of the most striking figures of his time in England. He was not a great scholar, and he left no writings that entitle him to remembrance; but by his clear view of the urgent need of reform in the church, and by the intensity of his religious convictions, he gave an impulse to men like Sir Thomas More and Erasmus, which influenced their whole life-work. At the same time, Colet, though an ardent religious reformer, never entertained the thought of a formal rupture with Rome. His foundation of St Paul's School, and the character he gave to that institution, entitles him to an eminent place among educational reformers. See Seebohm's *Oxford Reformers* (2d ed. 1869), and the Rev. J. H. Lupton's *Life of Colet* (1887).

Colewort. See CABBAGE.

Colfax, SCHUYLER, American statesman, born at New York, 23d March 1823, removed in 1836 to

Indiana, where in 1845 he acquired a newspaper at South Bend, which he made the most influential Whig journal in the district. He was a delegate to the Whig conventions of 1848 and 1852; he was returned to congress in 1854 by the newly-formed Republican party, and re-elected until 1869, being thrice chosen Speaker; and in 1868 he was elected vice-president of the United States, in Grant's first term. Implicated, apparently unjustly, in the Crédit Mobilier charges of 1873, he spent the remainder of his life in political retirement, making public appearances only on the lecture platform, and died at Mankato, in Minnesota, 13th January 1885. See his *Life* by O. J. Hollister (New York, 1886).

Colibri. See HUMMING-BIRD.

Colic (Gr. *colon*, 'the large intestine'; see INTESTINES), a name employed by the later Greek and the Roman physicians to denote diseases attended with severe pain and flatulent distension of the abdomen, without diarrhœa or looseness of the bowels. The disease (commonly called *gripes* or *belly-ache*) is now generally believed to be spasmodic in character, and to be dependent upon irregular contractions of the muscular coat of the intestines: its supposed particular connection with the colon, or large intestine, however, is not usually to be made out from the symptoms. Painful disorders of the bowels are very frequent in persons who are not attentive to the regular evacuations, especially when they are exposed to cold so as to experience chill or coldness of the feet, which will often suffice to bring on an attack of colic. The disease is usually attended with Constipation (q.v.), and ceases when the regular action of the bowels is restored, although often in this case the operation of medicine is attended by continued pain for a time. Warm fomentations to the abdomen may be employed with advantage, sometimes medicated with opium, or decoction of poppy-heads; and great relief is commonly experienced from friction with a warm liniment, such as opodeldoc, or the soap and opium liniment. Pressure with the hand over the painful part commonly diminishes the suffering for the time in simple colic, but increases it in more serious diseases. Warmth to the feet, and the recumbent posture, are also to be recommended. In very severe or protracted cases opium may be taken internally. A good remedy in such cases is a full dose of castor-oil (one ounce or more for an adult), with 30 or 35 drops of laudanum, or of solution of morphia. (Opates should not be given to children except under medical advice, and in very reduced doses.) When colic resists such mild and simple remedies as the above—when it is accompanied by tenderness of the belly, or by hard swelling in any part of it—when constipation is obstinate, or vomiting is present—when there is feverishness, or tendency to exhaustion—or when there is reason to believe that it may depend on any other cause than the mere accumulation of the products of digestion in the intestines, no time should be lost in seeking the best medical assistance that can be procured; for colic is closely allied as a symptom to several very severe and dangerous diseases. One of these complicated forms of colic is termed *Ileus*, or *iliac passion* (from the idea that its seat was in the small intestine—*ileum*). It is attended with obstruction of the bowels, often from mechanical twisting or involution of one part with another (hence termed *volvulus*). This is, of course, a disease of extreme danger. The only treatment that can be attempted without medical assistance is the employment of large injections by the lower bowel, and opium in moderate and repeated doses ($\frac{1}{2}$ grain to 1 grain, or 12 to 20 drops of laudanum) by the mouth, care-

fully watched, and discontinued if there is any sign of narcotism (see OPIUM). Colic pains are also present in Peritonitis (q.v.), another most dangerous form of disease; and they form one marked symptom of the slow poisoning by lead, occasionally observed as the consequence of contamination of drinking water by leaden cisterns, &c. In this form, the treatment is different from that of simple colic, and will be treated of under LEAD-POISONING.

Coligny, GASPARD DE, one of the greatest Frenchmen of the 16th century, was born at Châtillon-sur-Loing, February 16, 1517. At the age of twenty-two he began his career as a soldier, and greatly distinguished himself in the wars which Francis I. and Henry II. carried on against Spain. By Henry II. he was appointed colonel-general of the French infantry, and the severe system of discipline he introduced gave a new character to the art of war in the 16th century. In 1552 he was made admiral of France, though he never commanded on the sea. By holding the town of St Quentin (1557) with a handful of men for seventeen days against the army of Spain, he was the means of saving his country. It was during his imprisonment, after the capture of this town, that he embraced the views of the Huguenots, to the furtherance of which the rest of his life was consecrated. On the accession of Francis II. in 1559, the Guises became all-powerful, and their interest and fanaticism led them to oppose all toleration of the Huguenots. To obtain this toleration, however, was Coligny's great aim, and by his high character and his abilities as a statesman and general, he succeeded in conjunction with the heads of the Bourbon family in effecting the treaty known as the 'Pacification of Amboise' (1563), by which the Huguenots were allowed freedom of worship. This concession having been gradually withdrawn by the queen-mother, Catharine de' Medici, the second Huguenot war broke out in 1567, when, on the death of the Prince of Condé, Coligny was appointed generalissimo of the forces of Henry of Navarre, afterwards Henry IV. of France. Both parties having grown weary of the war, peace was concluded in 1570 on the basis of the treaty of Amboise, mainly through Coligny's energy. Catharine de' Medici, however, again becoming alarmed at the growing power of the Huguenots, and especially at the ascendancy of Coligny over the young king, Charles IX., determined by one desperate stroke to regain her power. In 1572, a numerous body of the Huguenot nobles having been drawn to Paris by the marriage of Henry of Navarre with Margaret, the sister of the king, the massacre of St Bartholomew took place, when Coligny was murdered in his bed, and his body thrown into the street by Henry of Guise and his followers.

In his personal character Coligny was one of the noblest Frenchmen of his time. His religious zeal was purely disinterested, and he had deeply at heart the welfare of his country. His great aim was to make the Huguenots a national party, and by their enthusiasm to defeat the schemes of Spain, who he saw was bent on supremacy in western Europe. Had he lived a few years longer the history of French Protestantism would have been different. Coligny's wide views are further seen in his unsuccessful attempts to found Protestant colonies in Brazil and North America. See his *Life* by Blackburn (2 vols. Phila. 1869), Bersier (Eng. trans. 1884), and Delaborde (3 vols. Paris, 1880).

Colima, a Mexican state on the Pacific coast, with an area of 2694 sq. m., and a pop. (1882) of 72,591. The soil is very fertile, the climate warm;

large quantities of coffee, sugar, rice, tobacco, maize, and cotton are grown. The capital, Colima, 1450 feet above the sea, about 40 miles ENE. of the port of Manzanillo, is regularly built, with narrow streets crossing at right angles, and has several large cotton-factories. Pop. (1882) 26,251. Beyond the state frontier, about 35 miles NE. of the capital, rises the volcano of Colima (12,750 feet), which burst out in June 1869.

Collin. See VIRGINIAN QUAIL.

Coliseum. See AMPHITHEATRE.

Coll. one of the Argyllshire Hebrides, 16 miles W. of Tobermory in Mull. It is 13 miles long, 1 to 3½ broad, and 30 sq. m. in area. It nowhere exceeds 326 feet in height; mica-slate is the predominant rock; and more than a third of the surface is cultivated or in pasture. Pop. (1801) 1162; (1881) 643.

Collar-bone, or CLAVICLE (q.v.), is in man, as in most mammals, the only bone directly connecting the upper extremity with the skeleton of the trunk. It is consequently very often broken, more often than any other bone except perhaps the radius. Under proper treatment, in children sometimes even without treatment, it readily reunites without any impairment of the usefulness of the limb. But it is very difficult to maintain such exact adjustment that no irregularity of the surface of the bone will remain; and as it lies close under the skin, the resulting deformity is often visible.

Collateral. See CONSANGUINITY, SUCCESSION. Collateral Security is an additional and separate security for the performance of an obligation.

Collation. See BENEFICE.

Collé, a town of Italy, on the Elsa, 24 miles SSW. of Florence. It has an old cathedral and castle. Pop. 5090.

Collect, a short form of prayer, peculiar to the liturgies of the Western Church. It consists of a single sentence, conveying one main petition, which is based on an attribute ascribed to God in the opening invocation, and closing with an ascription of praise or a pleading of the merits of Christ. Thus much for the structure of these prayers, which, whether in Latin or English, may be described, alike from their noble rhythmical harmony and from their pathos and devout simple earnestness, as models of liturgical petitions; the etymology of their name is more difficult to determine, beyond the fact that it is from the Latin *colligere*, 'to collect.' According to some, the prayer was so called because, as in the English Prayer-book, it collects or condenses the teachings of the epistle and gospel for the day; but this explanation applies only to the class of special collects. According to others, the term implies that the prayer collects and sums up all the previous petitions, or gathers and offers up in one comprehensive form all the spoken and unspoken petitions of the people. Both these derivations are open to serious objections, and neither has any historical basis; the most probable view is that which traces the name to the *collecta*, or assembly of the people for divine service, at which certain prayers (*orationes ad collectam*) were said, distinct from the later prayers of the mass (*orationes ad missam*). Of the collects used in the liturgy of the Church of England, some, including most of those for saints' days—since the old collects were mainly prayers for the saints' intercession—were composed at the Reformation, or even later; but most, taken from the old Roman Missal, are derived from the Sacramentaries of Popes Leo, Gelasius, and Gregory (5th and 6th centuries). The remoter source of the weekly

collects Freeman finds in the hymns of the Eastern Church, founded on the gospels, of which these collects would thus be the 'very quintessence.' In the *English Prayer-book*, for every Sunday there is a proper collect, with corresponding epistle and gospel; and this collect stands for every day in the following week, except in the case of festivals and their eves or vigils, which have collects of their own. Good Friday alone has three collects; and during Advent and Lent the collect for the first day of the season is repeated after the collect for the week.

Collections at Churches. The collections which are still made at all churches in Scotland—either at the church-doors before the service, or in the church after it—were, till a comparatively recent period, the principal fund for the support of the poor. The proceeds of these collections were originally under the control of the kirk-session, and remain so under certain restrictions. By a proclamation of the Privy-council in 1693, it was ordered that one-half of the sums so collected, and of dues received by the kirk-session, be paid over into the general fund for the support of the poor. The other half has generally been applied for the relief of sudden or temporary distress. The kirk-session may be called upon by any single heritor to account for its management of this remaining half. By the Poor-law Amendment Act, 1845, it is enacted that in all parishes in which it has been agreed that an assessment shall be levied for the relief of the poor, all moneys arising from the ordinary church collections shall in future belong to, and be at the disposal of, the kirk-session; provided, however, that they shall be applied to no purposes other than those to which they were, in whole or in part, legally applicable before the date of the act. A power is reserved to the heritors to examine the accounts of the kirk-session, and to inquire into the manner in which the collections are applied; and the session-clerk is enjoined to report annually as to the application of the moneys, to the Board of Supervision. The collections made at Dissenting meeting-houses, under which denomination Episcopal chapels are included, are entirely at the disposal of the congregations, and do not form part of the poor's funds. The making of a collection is properly the province of the minister and elders; but when they neglect the duty the heritors have been in use to perform it. See *Black's Parochial Ecclesiastical Law of Scotland* (1888), p. 145.

In England there are no regular collections at churches as in Scotland. The alms collected in chapels, as well as in parish churches, during the reading of the offertory, are declared by the rubric to be at the disposal of the incumbent and churchwardens of the parish, and not of the minister or proprietor of the chapel. If the minister and churchwardens disagree as to the distribution of the alms, they shall be disposed of as the ordinary shall appoint.

Collectivism is a word of recent origin, intended to express the central idea in the economic theory of socialism, that industry should be carried on with a collective capital. It means that capital should not be owned and controlled by individuals, but by groups of associated workers, that it should be the joint property of the community or other form of social organisation. Its exact meaning depends very much on the form of socialism with which the principle is connected. See **SOCIALISM**.

College (Lat. *collegium*, 'a collection or assemblage'). In its Roman signification, a college signified any association of persons for a specific purpose, and was in many cases practically what we call a corporation. It required also to be incorporated by some sort of public authority, springing

either from the senate or the emperor. A college could not consist of fewer than three persons, according to the well-known maxim, 'three make a college' (Dig. 50, tit. 16, l. 85). Some of these colleges were for purely mercantile purposes, but there were others which had religious objects in view, such as the colleges of pontifices and augurs, &c., and some were political, as the colleges of the tribunes of the plebs. With us, a college is an incorporation, company, or society of persons joined together generally for literary or scientific purposes, and frequently possessing peculiar or exclusive privileges. See **PHYSICIANS (COLLEGE OF)**, **SURGEONS (COLLEGE OF)**, **HERALDS' COLLEGE**. Very often in England a college is an endowed institution connected with a university, having for its object the promotion of learning. In this relation a college is a sub-corporation—i.e. a member of the body known as the university. For a more detailed account of college in this sense, see **UNIVERSITY**, **OXFORD**, **CAMBRIDGE**. In Scotland and in America the distinction between the college as the member and the university as the body has been lost sight of; and we consequently hear of colleges granting degrees, a function which in the English and in the original European view of the matter belonged exclusively to the university. Where there is but one college in a university, as is the case in Edinburgh and Glasgow universities, the two bodies are of course identical. Trinity College, Dublin, is practically the university. Owens College is a branch of the Victoria University. University College is a very usual name for recently founded institutions for the higher learning in the United Kingdom. Some of the public schools are colleges, and many secondary schools are so called. Theological schools often bear this name, which is sometimes given to a hospital. In Germany there are no colleges in the English sense. In France the name of college is sometimes given to the local branches of the University of France (q.v.); as also to a school, corresponding, however, more to the Gymnasium (q.v.) of Germany than to the grammar-school of this country. The principal colleges have articles under special heads; see **KING'S COLLEGE**, **UNIVERSITY COLLEGE (LONDON)**.

Collège de France, originally a *Collège de Trois Langues* merely, founded by Francis I. in 1530, is now a very important educational institution giving instruction over a very wide field of literature, history, and science. It is independent of the University of France (q.v.), is directly under the Minister of Public Instruction, and is supported by the government. As in the Sorbonne (q.v.), the lectures are gratuitous; and for the most part are designed to attract auditors older than ordinary university students. The college comprises two faculties, one literary, one scientific; and each has about twenty professors. Amongst the professors have been some of the most distinguished scholars and scientists in France, such as M. Renan, M. Laboulaye, M. Gaston de Paris, in the literary department; and M. Brown-Séquard in the science division. Amongst the subjects discussed are political economy, Assyrian and Egyptian archaeology, Arabic, Slavonic literature, French literature; physiology, anatomy, and embryology.

College of Arms. See **HERALD**.

College of Justice. See **COURT OF SESSION**.

Collegiate Churches—so called from having a college or chapter, consisting of a dean or provost and canons, attached to them—date from the 9th century, when such foundations in large towns became frequent. They are under the jurisdiction of the bishop of the diocese in which they are situated, and he exercises visitatorial powers over them. There were about ninety collegiate churches

in England and Wales at the beginning of the 16th century, but nearly all of them were suppressed or dissolved in Edward VI.'s reign under the Acts of Henry VIII, which followed upon the dissolution of the monasteries, and granted the hospitals, chantries, and colleges to the crown. Those remaining in England are Westminster, Windsor, Wolverhampton, Haytesbury, Middleham; also Brecon in Wales, and Galway in Ireland. Ripon, Manchester, and Southwell have been constituted the cathedrals of new dioceses. Some churches called collegiate (such as Beverley) have no chapters. In the Roman Catholic Church, no new collegiate church can be founded without the sanction of the pope, acting on the favourable report of the Congregation of the Council of Trent, that the necessary conditions have all been fulfilled, such as suitable population and locality, adequate buildings, sufficient endowments, and the assent of the diocesan bishop; while a priority of rank in their class is conceded to some such churches, distinguished by the title 'eminent' (*insignis*). The *History of Renfrewshire* (1886) contains a very full and interesting account of the collegiate church of Castle-Semple, founded in 1504.

Collem'bola, the name given by Sir John Lubbock to a tribe of wingless insects, to which the Podura (q.v.) or spring-tail belongs; though he and other entomologists question their claim to be called insects.

Colley, SIR GEORGE, major-general, was born in 1835, and in 1852 received an ensigncy in the 2d or Queen's Foot, whose headquarters, then in the eastern frontier of Cape Colony, he joined in 1854. He was a border magistrate in 1857-58, surveyed the Trans-kei country, and served with his regiment in China in 1860. He was then for some years major of brigade at Plymouth, and a professor at the Staff College. He ably managed the transport service in the Ashanti expedition, and in 1875 accompanied Sir Garnet Wolseley to Natal, where he was for some time colonial treasurer, and prepared a valuable report and map of the Transvaal and Swaziland. From 1876 to 1880, except for a short period of service as chief of Wolseley's staff in Zululand and the Transvaal, he was private secretary to Lord Lytton, then viceroy in India. Appointed governor and commander-in-chief of Natal in April 1880, he commanded his small force against the Boers at Laing's Nek and Ingogo, and fell, shot through the forehead by a rifle-bullet, in the attack on Majuba Hill, February 27, 1881.

Collie. The origin of the collie is somewhat obscure, but great antiquity is claimed for it. Buffon has gone so far as to call it the oldest known breed of dogs, an opinion not now generally entertained; though it is only reasonable to suppose that the ancients, after providing a dog for the chase, next turned their attention to obtaining a guardian for their flocks. For many years collies were confined to Scotland and the northern counties of England, until their good points as a graceful and intelligent companion attracting more attention, they were taken south in large numbers, and became the most popular breed of the day. Thanks to judicious breeding and a large expenditure of money, the best show collies are now all found in England. Tempted by the demand for black-and-tan dogs, a cross with the Gordon setter was resorted to, producing many collies with the flat ears and open coat of the setter, a cross to be avoided at all costs. In judging the collie the fact should never be forgotten that it is meant to do work in all weathers, requiring the best of legs and feet, a close coat, and a strong active body capable of great speed; and that a long and beautiful coat, if unaccompanied by a thick under-coat,

is a hindrance, not a protection. The chief points of the collie are—head long and sharp, with bright, keen eyes, set rather close together, and a small ear drooping slightly at the tips; back strong and muscular; legs with plenty of bone and not too much feather, bare below the hocks; feet

Collie.

round and cat-like. The collie should have a short dense under-coat fitted to withstand the severest wet or cold, with a long and beautiful outer-coat springing from it; round the neck this coat develops into a 'ruff' or 'frill' which sticks out in front and on each side to a great length, adding largely to the dog's beauty. Many anecdotes are told of the collie, who from his intimate association with man has acquired almost human intelligence, a good dog being able to separate the sheep under his care from those of other flocks. The collie often deteriorates in intelligence when kept merely as a companion; he is apt to get cross-tempered, a fact which the shepherd does not consider a fault, as it prevents strangers interfering with the sheep. But when not spoilt no dog makes such an agreeable companion as the collie, as his instinct is to attach himself to one person to whom he becomes devoted.

Collier, ARTHUR, metaphysician, the son of a clergyman, was born in 1680 at Langford Magna, Wiltshire, studied at Oxford, and became rector of the family living at Langford in 1704, remaining there till his death in 1732. At Balliol College, Collier had devoted himself to the study of Descartes and Malebranche; and his notable book, *Clavis Universalis, or a New Inquiry after Truth, being a Demonstration of the Non-Existence and Impossibility of the External World* (which, though published in 1713, was written ten years before), coincides in a remarkable way with Berkeley's *Theory of Vision* (published 1709). He was a High-Churchman, and wrote also *A Specimen of True Philosophy* (1730) and a *Logology* (1732).

Collier, JEREMY, nonjuror and purifier of the English stage, was born at Stow cum Quy, in Cambridgeshire, 23d September 1650. His father was a clerical schoolmaster at Ipswich, and here and at Caius College, Cambridge, he was educated, graduating B.A. in 1672. For six years he was rector of Ampton, near Bury St Edmunds, and for some years before the Revolution he was lecturer at Gray's Inn. His reply to Dr Gilbert Burnet's *Inquiry into the State of Affairs* (1688) cost him some months' imprisonment in Newgate. He next waged warfare on the crown with a succession of incisive pamphlets, carrying his refusal to recog-

nise the authority of the government so far as hardly to be persuaded by his friends to let them bail him out of prison when arrested in 1692 on suspicion of being involved in a treasonable plot. In 1696, along with two other clergymen, he outraged public feeling by solemnly pronouncing absolution, without any public confession, on the scaffold at Tyburn upon the heads of Friend and Parkyns just before their execution for a plot to murder the king. For this gross and public offence he was obliged to go into hiding, but though he was formally outlawed, no attempt was made to punish him. In 1697 he published his famous *Short View of the Immorality and Profaneness of the English Stage*, which fell like a thunderbolt among the wits. The boldness of the onslaught can only be understood by remembering the greatness of the odds and the might of his antagonists. 'It is inspiring,' says Macaulay, 'to see how gallantly the solitary outlaw advances to attack enemies, formidable separately, and, it might have been thought, irresistible when combined, distributes his swashing blows right and left among Wycherley, Congreve, and Vanbrugh, treads the wretched D'Urfey down in the dirt beneath his feet, and strikes with all his strength full at the towering crest of Dryden.' Collier's argument carried the country with it, and brought back the English drama to good morals and good sense. That excessive stage-profligacy which was a mere reaction against the rigidity of Puritanism, and had far outrun the parallel laxity of contemporary social morals, at once disappeared, and the theatre in England again became a mirror in which nature and truth were reflected without distortion. But it was not without a struggle that the wits consented to be worsted. Congreve and Vanbrugh, with many of the smaller fry, answered angrily but weakly, and were crushed anew by the redoubtable nonjuror, who was 'complete master of the rhetoric of honest indignation.' 'Contest,' says Dr Johnson, 'was his delight; he was not to be frightened from his purpose or his prey.' The great Dryden stood apart at first, but at length in the preface to his *Fables* (1700) acknowledged with a noble honesty that he had been justly reprov'd. 'I shall say the less of Mr Collier,' he says, 'because in many things he has taxed me justly; and I have pleaded guilty to all thoughts and expressions of mine which can be truly argued of obscenity, profaneness, or immorality, and retract them. If he be my enemy, let him triumph; if he be my friend, as I have given him no personal occasion to be otherwise, he will be glad of my repentance. It becomes me not to draw my pen in the defence of a bad cause, when I have so often drawn it for a good one.' But Dryden complained, and fairly, that his antagonist had often perverted his meaning, that he was 'too much given to horse-play in his railery, and came to battle like a dictator from the plough.' Spite, however, of all its pedantry and overstatement of the case, and its faults of taste and of relative proportion in charges made with equal indignation, the *Short View* was a noble protest against evil, and was as effective as it deserved to be.

Collier continued to preach to a congregation of Nonjurors (q. v.), and was consecrated bishop in 1713. A great controversy soon rent the nonjuring community on the lawfulness of returning to certain 'usages' allowed in the communion-office of the first prayer-book of Edward VI., which Collier's party preferred to the revision of 1552. Collier at length pronounced these usages *essential*, and not unnaturally laid himself open to a charge of holding Romish views. He masqueraded as 'Jeremias, Prinus Anglo-Britannicæ Episcopus' in some abortive attempts to form a union with the Eastern

Church. His last years were racked by the torments of the stone, from which he found relief in death, April 26, 1726. Of his forty-two books and pamphlets, those on the stage alone are still read. The fifth edition of his famous treatise (1730) contains all the successive pamphlets which fortified the first. His largest works were the *Great Historical, Geographical, Genealogical, and Poetical Dictionary* (4 vols. folio, 1701-21), and *An Ecclesiastical History of Great Britain . . . to the end of the Reign of Charles II.* (2 vols. folio, 1708-14; new ed. by T. Lathbury, with Life, 9 vols. 1852).

Collier, JOHN, known under the pseudonym of 'Tim Bobbin,' was the son of the curate of Stretford, near Manchester, and from 1739 to his death in 1786 was master of a school at Milnrow, near Rochdale. He early wrote verse and painted grotesque pictures; his rhyming satire, *The Blackbird*, appeared in 1739, and his *View of the Lancashire Dialect* (in humorous dialogue), his most notable production, in 1775. It has been often reprinted. Other works are *Truth in a Mask*, *The Fortune-teller*, and *The Human Passions* (120 engravings, with verse descriptions).

Collier, JOHN PAYNE, Shakespearian critic and commentator, was born in London, 11th January 1789, son of an unprosperous merchant who had succeeded as a reporter and journalist. His parents were friends of Lamb, Hazlitt, Coleridge, and Wordsworth. The boy passed some years at Leeds, and early began to write. Still a boy, he became parliamentary reporter for the *Times*, next for the *Morning Chronicle*, and wrote regularly for the latter down to 1847. His call to the bar was delayed till 1829, probably through the odium he incurred by a foolish volume of satirical verse. His real literary career commenced in 1820 with the publication of *The Poetical Decameron*. From 1825 to 1827 he issued a new edition of *Dodsley's Old Plays*, and in 1831 his best work, a *History of English Dramatic Poetry to the Time of Shakespeare, and Annals of the Stage to the Restoration*. This opened up to him the libraries of Lord Francis Gower, afterwards Lord Egerton and Earl of Ellesmere, and of the Duke of Devonshire, the latter appointing him his librarian. From 1835 to 1839 Collier published his *New Facts* regarding the life and works of Shakespeare, followed by an edition of Shakespeare (8 vols. 1842-44), and supplemented by *Shakespeare's Library* (2 vols. 1844), a reprint of the histories, novels, and early dramas on which Shakespeare founded his plays. He was one of the leading members of the Camden Society from its foundation in 1838, and he edited for its issues *Bale's Kyng Johan* (1838), the *Egerton Papers* (1840), and the *Trevelyan Papers* (1857 and 1863). He contributed ten publications (1840-44) to the Percy Society, and twenty-one (1841-51) to the Shakespeare Society, of which he was long director. In 1852 he announced his discovery of an extensive series of marginal annotations in a 17th-century hand on a copy of the second Shakespeare folio (1631-32) he had bought—the famous Perkins folio, so called from a name inscribed on the cover. Late in the same year he published these to the world as *Notes and Emendations to the Plays of Shakespeare*, and calmly lifted them into the text in his 1853 edition of Shakespeare, and again in his annotated six-volume Shakespeare in 1858. The emendations caused a great commotion in the literary world, and were furiously applauded or furiously assailed. The best Shakespearian students were more or less sceptical, but C. W. Singer and E. A. Brae were the first to express openly an unfavourable opinion. The latter also attacked Collier's alleged discovery of his suspiciously long-

lost notes of Coleridge's lectures on Shakespeare and Milton, delivered in 1811. Collier, in the course of abortive proceedings for libel against Brae's publisher, swore to the truth of his statements respecting both the Perkins folio and his Coleridge notes. Meantime he had been judicious enough to keep his folio from the eyes of experts, but at length in 1859, the Duke of Devonshire, to whose predecessor Collier had given it in 1853, sent it, at Sir F. Madden's request, to the British Museum for examination. The result was a conclusive proof, by Mr N. Hamilton in letters to the *Times*, and more completely in his *Inquiry* (1860), that the boasted 17th-century emendations were entirely recent fabrications. Still further forgeries were later brought to light in Mr Warner's Catalogue of MSS. at Dulwich College (1883), from which Collier had prepared three publications for the Shakespeare Society. Collier replied angrily in the *Times*, in his long *Reply* (1860), the disingenuousness of which injured his reputation as much as the facts of his antagonist. The controversy widened, but every competent writer concluded against Collier, the only question that remained uncertain being whether he himself was merely a dupe or more. Unhappily for the name of a sound scholar ruined by one fatal weakness, this too was answered by the discovery after his death of some manipulated books in his own library. In 1847 Collier was named secretary to the Royal Commission on the British Museum, and in 1850 he removed to Maidenhead, where he died 17th September 1883. He had enjoyed since October 1850 a civil list pension of £100. His later books were *A Book of Roxburghe Ballads* (1847), *Extracts from the Registers of the Stationers' Company* (2 vols. 1848-49), *The Dramatic Works of Thomas Heywood* (1850-51), a good edition of Spenser (5 vols. 1862), a series of small reprints of rare 18th and 17th century pieces in prose and verse (1863-71), *Bibliographical and Critical Account of the Rarest Books in the English Language* (1865), and *An Old Man's Diary Forty Years Ago* (1871-72). See Dr Ingleby's *Complete View of the Shakspeare Controversy* (1861), which contains a bibliography of the books.

Colliers and Salters. See SERFDOM.

Collimator, a subsidiary telescope used to detect or correct errors in collimation (i.e. in directing the sight to a fixed object) when adjusting for transit observations. When the vertical thread in the field of view exactly coincides with the vertical axis of a telescope, the instrument is *collimated* vertically; and when the horizontal spider's thread just covers the horizontal axis, the instrument is correct in horizontal collimation. If

three solid piers stand on the meridian, so that the telescope to be tested can be laid between the collimators and have its axis coincident with both of theirs, the principle of correction becomes almost self-obvious. Removing the great telescope, the collimators (AA' and BB' in fig.) are adjusted till

the cross-wires in one coincide perfectly with those of the other in all possible positions. Then replacing the 'transit circle,' it is examined and tested by reference, first to one, and then the other collimator, the verification requiring that it be turned through 180° till the threads in the three fields of view absolutely coincide, and the collimation is pronounced perfect.

Practical astronomers set great value on the collimator (in the arrangement just described) for having entirely superseded the 'meridian mark.' By Rittenhouse's principle a telescope can become its own collimator, especially in determining the nadir point. When the axis is vertical over a vessel containing mercury, the telescope will be collimated when the cross-wires are brought to exact coincidence with their image seen in the mercury. See TELESCOPE.

Collingwood, a town of Ontario, on the south shore of Georgian Bay, where it connects the railways with the Huron lake steamers. It has several factories, ship-yards, and grain-elevators, and a considerable trade in lumber and grain. Pop. (1871) 2829; (1881) about 5000.

Collingwood, CUTHBERT, Lord, admiral, was born at Newcastle-upon-Tyne, 22d September 1750. Sent to sea as a volunteer at the age of eleven, his life thenceforth, with the exception of some half-dozen years, was spent chiefly on board ship. From 1778 his career was closely connected with that of Nelson, whom he followed up the ladder of promotion step by step, until Nelson's death left the topmost round vacant for himself. Among the great naval victories in which Collingwood bore a prominent part, were those of Lord Howe off Brest in 1794; of Lord Jervis off Cape St Vincent in 1797; and of Trafalgar in 1805, where he held the second command. In the last-named engagement, his ship was, by Nelson's command, the first to break through the line of the combined French and Spanish fleets; and after Nelson had received his death-wound, he assumed the chief direction. A peerage was his reward for his gallant conduct in this battle. After several years' uneventful service in the Mediterranean, he died at sea, March 7, 1810, but was buried beside Nelson, in St Paul's. Collingwood was not the stuff great tacticians are made of, and his talents as a commander-in-chief were at best but mediocre; but he was a brave and capable seaman, earnest and pious as a man, firm and mild as an officer, and admirable as a second in command. See his *Correspondence and Life*, by his son-in-law (1828).

Collins, ANTHONY, deist, was born 21st June 1676, at Heston, near Hounslow, in Middlesex, and was the son of a country gentleman. He studied at Eton and at King's College, Cambridge, and became the disciple and friend of John Locke. In 1707 he published his *Essay concerning the Use of Human Reason*; and in 1709, his *Priestcraft in Perfection*. The controversy excited by this last work induced Collins to write his *Historical and Critical Essay on the Thirty-nine Articles*. His next work was a *Vindication of the Divine Attributes*, in reply to King, Archbishop of Dublin, who asserted the compatibility of Divine Predestination and Human Freedom. Collins was a philosophical Necessitarian, and afterwards advocated his opinions more fully in his *Philosophical Inquiry concerning Liberty and Necessity* (1715). In 1711 he visited Holland, where he made the friendship of Le Clerc and other eminent literati. In 1713 he published his *Discourse on Free-thinking*, the best known, and the most important of all his works; to it Bentley made reply in his famous *Remarks*. In 1713 Collins made a second visit to

Holland; and in 1718 he was made treasurer for the county of Essex. In 1724 appeared his *Grounds and Reasons of the Christian Religion*. The contention that no fair interpretation of the Old Testament prophecies will secure a correspondence between them and their alleged fulfilment in the New Testament, created a violent controversy, and called forth no fewer than thirty-five replies. Two years later he defended himself in his *Scheme of Literal Prophecy*; and in 1727 he published his last work, the *Scheme of Literal Prophecy Considered*. Collins died 13th December 1729.

Collins, MORTIMER, a versatile writer, was born, the son of a solicitor at Plymouth, June 29, 1827. He was educated at private schools, and held for some years a mathematical mastership in Guernsey, which he resigned in 1856 to devote himself entirely to literature. He settled at Knowl Hill in Berkshire, and kept up an incessant activity in the varied forms of articles on current politics, novels, and playful verses until his death, 28th July 1876. His physical was equal to his mental vigour: he was tall and remarkably strong, an athlete, a lover of dogs, flowers, and outdoor-life. His old-world Toryism and hatred of irreverence and irreligion; his humour, his wonderful facility in extemporising clever verse, his chess-playing, not to say his mathematics, made him a delightful companion; and endeared him to such friends as R. H. Horne, Frederick Locker, Edmund Yates, and R. D. Blackmore. His volumes of verse were *Summer Songs* (1860), *Idyls and Rhymes* (1865), and *The Inn of Strange Meetings* (1871). Of his numerous novels the chief are *Sweet Anne Page* (1868); *The Marquis and Merchant* (1871); *Two Plunges for a Pearl* (1872); *Mr Carington*, by 'Robert Turner Cotton' (1873); *Transmigration* (1874); *From Midnight to Midnight* (1875); and *A Fight with Fortune* (1876). His second wife, who died March 17, 1885, collaborated with him in *Frances* (1874), *Sweet and Twenty* (1875), and in two novels published posthumously, *The Village Comedy* (1876) and *You Play me False* (1878); and wrote alone *A Broken Lily* (1882). One of his most popular books was *The Secret of Long Life* (1871), a collection of essays at first published anonymously. The pious affection of his friends kept his memory green by editing from his papers *Pen Sketches by a Vanished Hand*, by Tom Taylor, (1879); *Attic Sult*, a selection of epigrammatic sayings from all his books, by F. Kerlake (1880); and *Thoughts in My Garden*, by E. Yates (1882). See his wife's account of his Life (1877), and his *Select Poetical Works* (1886).

Collins, WILLIAM, a distinguished English poet, was born at Chichester, 25th December 1721. His father was a hatter in that town, of which he was several times mayor. Collins received the rudiments of his education at the prebendal school of his native town. At the age of twelve he was sent to Winchester School, where he remained seven years. While there he wrote his *Oriental Eclogues*, which in his own day, and for a considerable period afterwards, were the most popular of his productions. He was himself convinced that this preference was misplaced, and the world has long since come round to his opinion. In 1741 he proceeded to Oxford, where he was distinguished by 'his genius and indolence.' Having taken the degree of Bachelor of Arts in 1743, he shortly afterwards left the university for reasons which are not accurately known. His private means being but slender, he obtained the title to a curacy, but was dissuaded from entering the church. As his only other alternative, he took up his residence in London, and sought to make a living by literature, a profession for which he was utterly unfitted by his desultory

ways and uncertain health. He now fell into what are vaguely described as 'irregular habits,' and was at times reduced to the greatest straits. On one occasion Dr Johnson rescued him from the hands of bailiffs by obtaining an advance from a bookseller on the promise of Collins to translate the *Poetics* of Aristotle. It was during this period, however, that he wrote his Odes, upon which his fame as a poet now rests. They attracted no notice at the time of their publication, and they were little valued even by such contemporaries as Gray and Dr Johnson. By the death of an uncle in 1749, Collins inherited the sum of £2000, which enabled him to retire to Chichester, and apparently to pursue a regular course of study. It was about this time that he met Home, the author of *Douglas*, to whom he addressed his *Ode on the Popular Superstitions of the Highlands of Scotland*, a poem in which, according to Mr Russell Lowell, 'the whole Romantic School is foreshadowed.' The ode was first published in the Transactions of the Royal Society of Edinburgh (1788). Before 1753, Collins felt the approaches of the mental disease to which he finally succumbed, and sought relief in a visit to France. On his return he gradually became worse, and in 1753 his reason completely gave way. He lived for six years longer in this state, though with lucid intervals. He died on 12th June 1759, so unknown to fame that no newspaper or magazine of the day has any notice of his death.

Collins, like Gray, holds a middle position between the school of Pope and the school of Wordsworth. In his maturer work he is almost completely free from the so-called 'poetic diction' of the 18th century. He has not the passionate feeling for nature of later poets, but his feeling is at least real and not conventional. In respect of natural poetic gifts, Coleridge, and Mrs Browning, and other high authorities, place him above his contemporary, Gray. His choice of subjects, however, and his subtler modes of treatment, debar him from the popularity of the author of the *Elegy*. His most highly finished ode is that *To Evening*, which is unsurpassed for exquisiteness of tone and diction. The ode entitled *The Passions* has merits of a different order, but evinces genius of even wider scope. The allegorical character of this ode and its companion pieces, *To Liberty*, *To Mercy*, and *To Pity*, removes them from direct human sympathy. That Collins was capable of simplicity and pathos, however, is shown by his two most popular poems, *On the Death of the Poet Thomson*, and his lines beginning 'How sleep the brave.'

Collins, WILLIAM, R.A., landscape and figure painter, was born in London, September 8, 1788, of a Wicklow family. In 1807 he entered the Royal Academy as a student, and in the same year he exhibited two small landscapes. In 1812 his 'Sale of the Pet Lamb' was sold for 140 guineas, and from this time his pictures became popular. He exhibited 169 works, of which the best known are the 'Blackberry Gatherers' and 'The Birdcatchers' (1814), which gained his associateship; 'Scene on the Coast of Norfolk' (1815), now at Windsor; 'The Fisherman's Departure' (1826), 'As Happy as a King' (1836), and 'Early Morning' (1846). Collins was elected R.A. in 1820. He studied and sketched in Italy in 1836-38, and in 1839 sent to the Academy several Italian subjects. Two pictures on sacred subjects (1840-41) were not particularly successful, and he wisely fell back on his green fields, his sea-beaches, his rustics, and his children at their games. A visit to the Shetland Islands in 1842 supplied materials for the illustrations of Scott's *Pirate*. Collins died in London, February 17, 1847. See his Life (1848) by his elder son, William Wilkie Collins.—His second son, CHARLES ALLSTON COLLINS (1828-73), in early life painted

a number of pictures which are highly valued by collectors. In 1860 he married the younger daughter of Charles Dickens, and having already turned his attention to literature, produced *The Eye-witness essays* (1860), several novels, and other works, all exhibiting high promise.

Collins, WILLIAM WILKIE, novelist, elder son of William Collins, R.A., was born in London, 8th January 1824. He was educated partly at High-bury, but during 1836-39 was with his parents in Italy. After his return he spent four years in business, and then entered Lincoln's Inn; but gradually took to literature, the *Life of his father* (1848) being his earliest production. To it succeeded *Antonina, or the Fall of Rome* (1850); *Basil* (1852); *Hide and Seek* (1854); *The Dead Secret* (1857); *The Woman in White* (1860); *No Name* (1862); *Armadale* (1866); *The Moonstone* (1868); *The New Magdalen* (1873), &c.—in all, fully a score of novels and collections of novelettes. Several of them originally appeared in *Household Words*, *All the Year Round*, the *Cornhill*, and other periodicals. The best is *The Woman in White*, whose 'Count Fosco' is really a creation, and in which the author's almost invariable method of unfolding an intricate plot by narratives of the chief *dramatis personæ* had not grown hackneyed. *The Moonstone* also is a strong story.

Collinson, PETER, botanist, was born at Hugal Hall, near Windermere, 14th January 1694, and became a manufacturer of hosiery, having a large business with the American colonies. He was early distinguished as a naturalist, studied entomology and botany, and in 1745 communicated to Franklin his first intimation of the recent advance of electrical science in Europe. But it was as a botanist he was most distinguished. He introduced the culture of numerous European plants into the United States, and introduced American trees into England. He died 11th August 1768. A genus of labiate plants was named *Collinsonia* after him.

Collisions. See RAILWAYS, WRECK, RULE OF THE ROAD.

Collodion (Gr. *kollao*, 'I stick') is a solution of Gun-cotton (q.v.) or pyroxylin. Cotton itself is not soluble in alcohol or ether, but when treated, either in the form of cotton-wool, rags, or paper, with a mixture of five parts of strong nitric acid, and six of sulphuric acid, it is found that it can now be dissolved in ether, or in a mixture of ether and alcohol. To this modification the name pyroxylin is applied. There are many varieties of collodion divisible into surgical or medicated collodions, and photographic collodions. When one part of pyroxylin is dissolved in thirty-six parts of ether and twelve parts of alcohol, a thickish liquid is obtained, which evaporates rapidly, leaving a thin film of pyroxylin. As an application to wounds, where it is desired to keep the edges close together, this form of collodion is of use, owing to the contractility of the pyroxylin film which it leaves, but for general purposes a flexile or flexible collodion, as it is called, is desirable. This is produced by the addition of a little Canada balsam and castor-oil to the ordinary variety. Flexile collodion is largely used as a covering for abraded surfaces, as a remedy for burns, for sore nipples, &c., and it is also the basis for many medicated collodions, such as styptic collodion, cantharidal or blistering collodion, &c. Salicylated collodion is well known as a popular corn cure, and it is certainly most effectual in removing hard or soft corns with but slight inconvenience. It contains, in addition to salicylic acid, the active principle, a little extract of Indian hemp, which prevents the slight pain, which might otherwise prove

troublesome. Collodion plays a very important part in Photography (q.v.).

Colloid is a name applied by Graham to any soluble substance which, when exposed to *Dialysis* (q.v.), does not pass through the porous membrane. Starch, gum, albumen, and gelatin are examples of colloids; and the name is used in contradistinction to *crystalloids*.

Collet d'Herbois, JEAN MARIE, a French revolutionist of infamous notoriety, was born in Paris in 1750. Originally a provincial actor, he was attracted by the Revolution to Paris, where his impudence, his loud voice, and his *Almanach du Père Gérard*, secured him the public ear and his election for Paris to the National Convention. In 1793 he became president of the Convention and a member of the murderous Committee of Public Safety. Sent by Robespierre to Lyons in November of the same year, he took bloody revenge by guillotine and grapeshot on the inhabitants for having once hissed him off the stage in the theatre. His popularity at length exciting the envy of Robespierre, Collet d'Herbois for his own safety joined in the successful plot for the overthrow of Robespierre and his party in July 1794; but the reaction that followed this happy event proved fatal to himself. He was expelled from the Convention, and sentenced to deportation to Cayenne, where he died in misery that deep debauches could not stupefy, January 8, 1796.

Collusion, a deceitful agreement between two or more persons to defraud or prejudice a third person, or for some improper purpose. The most common cases of collusion occur in arrangements between bankrupts and their creditors, such as payment by anticipation to a favoured creditor on the approach of bankruptcy, arrangements for granting preferences by circuitous transactions or otherwise. Transactions in which there is evidence of collusion are reducible at common law, and many of the same nature are struck at by the bankruptcy statutes. Collusion in judicial proceedings is an agreement between two persons that one should institute a suit against the other in order to obtain a judicial decision for some sinister purpose. The judgment so obtained is null. Collusion between petitioner and respondent in a suit for dissolution of marriage bars the suit.

Collyrium is a term for various kinds of eye-salve or eye-wash.

Colman, GEORGE, commonly called 'the Elder,' a dramatic author and theatrical manager, was born at Florence in 1732. In 1760 his first dramatic piece, entitled *Polly Honeycomb*, was produced at Drury Lane with great success. Next year he gave to the world his comedy of *The Jealous Wife*, and in conjunction with Garrick, he wrote *The Claudestine Marriage*, which was played at Drury Lane, 20th February 1766. In 1767 he became one of the purchasers of Covent Garden Theatre, and held the office of acting manager for seven years, after which period he sold his share. In 1777 he purchased the patent of the theatre in the Haymarket from Mr Foote. In 1785 he was attacked by paralysis, which caused a gradual decay of his mental powers, and he died in confinement on 14th August 1794. Colman was an industrious author; besides poetry and translations, he wrote and adapted upwards of thirty dramatic pieces.

Colman, GEORGE, 'the Younger,' son of the preceding, was born October 21, 1762. His bent lay in the same direction as his father's, during whose illness he acted as manager of the Haymarket Theatre; and on the death of the elder Colman, George III. transferred the patent to his

son. Colman held, for a considerable time, the office of Examiner of Plays, to which he was appointed on 19th January 1824, and in which he behaved with great arrogance. In industry he rivalled his father, and he received large sums for his dramatic writings, some of which continue in possession of the stage. He was twice married, and died on the 17th October 1836. In 1830 he published a very imperfect autobiography, which he named *Records of My Life*; but his most notorious work is the preface to his play of *The Iron Chest*, in which he furiously attacked John Kemble.

Colman, SAMUEL, American painter, born in Portland, Maine, in 1832, studied in Europe in 1860-62, was elected a member of the National Academy in 1862, and first president (1866-71) of the American Society of Painters in Water-colours. He has travelled extensively, and his pictures include scenes from Algeria, Germany, France, Italy, and Holland.

Colmar, the capital of the German district of Upper Alsace, stands on a plain near the Vosges, 42 miles SSW. of Strasburg by rail. Among the principal public buildings of Colmar are the church of St Martin (1263), the Dominican convent of Unterlinden, now a museum, the college, court-house, and town-hall. Colmar is one of the chief seats of the cotton manufacture in Alsace. Other manufactures are paper, leather, ribbons, and hosiery. Colmar is an old place, having been raised to the rank of a free imperial city in 1226. It rapidly became one of the most prosperous towns in Upper Alsace. Fortified in 1552, its fortifications were razed in 1673 by Louis XIV. Pleasant boulevards now occupy their place. Colmar was formally ceded to France in 1697, but was recovered by Germany in 1871. Pop. (1875) 23,778; (1885) 26,537.

Colne, a town in the east of Lancashire, on a high ridge near the source of the Calder, a western branch of the Ribble, 26 miles N. of Manchester by rail. It has manufactures of cotton calicoes and mousselines-de-laine; and it was formerly a seat of the woollen industry. Slate and lime abound in the vicinity. Many Roman coins have been found at Colne. Pop. (1871) 7335; (1881) 10,313.

Colney Hatch, a village of Middlesex, 6½ miles N. of London, with a great lunatic asylum, opened in 1851.

Colocasia. See COCCO.

Colocynth (Gr. *kolokynthis*), a well-known medicine, much used as a purgative, is the dried and powdered pulp of the *Colocynth Gourd*, *Coloquintida*, *Bitter Apple*, or *Bitter Cucumber*, a globose fruit about the size of an orange, of a uniform yellow colour, with a smooth, thin, solid rind. The plant which produces it, *Cucumis* (or *Citrullus*) *Colocynthis*, is nearly allied to the Cucumber (q.v.). It is found very widely distributed over the Old World, growing in immense quantities on the sand hillocks of Egypt and Nubia. It is also common in India, Portugal, Spain, and Japan. It has long been known for its purgative properties, and as early as the 11th century was in use in Britain. The main supplies of the drug are obtained from Mogador, Spain, and Syria. The fruit is gathered when it begins to turn yellow, peeled, and dried quickly either in a stove or in the sun. It is chiefly in the form of a dried extract that it is used in medicine. It owes its properties to a bitter principle called *Colocynthinine*, which is more or less abundantly present in the fruits of many of the gourd family. It is a curious fact, but to which there are many analogies, that the seeds of the colocynth plant, produced in the midst of its medicinal pulp, are perfectly bland, and they even form an important article of food in the north

of Africa.—The name False Colocynth is sometimes given to the Orange Gourd (*Cucurbita aurantia*), sometimes cultivated as an ornamental plant in our gardens, on account of its globose, deep-orange fruit. The pulp of the fruit possesses the properties of colocynth, but in a milder degree.

Colocynth is generally administered in the form of pills, in which the extract is associated with aloes, scammony, and in some cases with calomel or with extract of hyoscyamus. In small doses, the colocynth acts as a safe and useful purgative; and when accompanied by hyoscyamus, the latter prevents much of the pain and griping which are attendant on the use of colocynth by itself. In large doses, colocynth is a poison. Colocynth enters into the composition of some moth powders, and renders them very efficacious.

Cologne (Ger. *Köln*), a city and free port on the left bank of the Rhine, 362 miles by rail WSW. of Berlin, 175 SE. of Rotterdam, 149 E. of Brussels, and 302 NE. of Paris. Formerly an independent city of the German empire, it is now the capital of Rhenish Prussia. Cologne is a fortress of the first rank, forming a semicircle, with the Rhine as its chord, and the town of Deutz on the opposite bank as a tête-du-pont. It is connected with this suburb by a bridge of boats, and an iron bridge 1362 feet in length, for railway and carriage traffic. Pop. (1871) 129,233; (1885) 161,401, only 25,115 of whom were Protestants. The old streets are mostly narrow and crooked; but the area freed by the removal of the ancient fortifications, which dated originally from the 13th century, is laid out on a more spacious plan. This area, which doubles that occupied by the old town, was purchased in 1882 by the corporation for about £600,000; its most prominent feature is the handsome 'Ringstrasse' or boulevard, nowhere less than 60 feet wide, which encircles the entire old town. The new fortifications include a number of detached forts, planted round Cologne and Deutz, within a radius of about 4 miles from the cathedral. The ancient buildings in Cologne, both secular and ecclesiastical, are of great architectural interest; the Romanesque and Transition styles are specially well represented in the numerous churches of the 11th, 12th, and 13th centuries. The church of St Maria im Capitol, consecrated in 1049, is the earliest example in Cologne of a church with a trefoil-shaped ground-plan for transepts and choir. In the church of St Ursula are preserved the bones of the 11,000 virgins, companions of St Ursula (q.v.). The church of St Gereon boasts of the possession of the bones of St Gereon, and of the 308 martyrs of the Theban legion, slain during Diocletian's persecution. The church of St Peter contains the altar-piece of the crucifixion of St Peter by Rubens, and that of the Minorites the tomb of the famous scholastic, Duns Scotus.

The chief object of interest in the city, however, as well as its greatest ornament, is the cathedral, one of the noblest specimens of Gothic architecture in Europe. This cathedral is said to have had its origin in an erection by Archbishop Hildebold, during the reign of Charlemagne in 814. Frederic Barbarossa bestowed upon it, in 1162, the bones of the three Magi (q.v.), which he took from Milan, and this gift greatly increased its importance. The bones are retained as precious relics to this day; but the old structure was burned in 1248. According to some accounts, the present cathedral was begun in the same year, but others fix the date of its commencement in 1270-75. To whom the design of this noble building is to be ascribed is uncertain. The choir, the first part completed, was consecrated in 1322. The work was carried on,

sometimes more actively, sometimes more slowly, till 1509, when it was suspended; and during the subsequent centuries what had been already executed was not properly kept in repair. Since

but a colony being planted here in 50 A.D. by Agrippina, the wife of the Emperor Claudius, it received the name of *Colonia Agrippina*. At the partition of the Frank monarchy in 511, it was

Cologne Cathedral.

the beginning of the 19th century, however, the necessary funds to repair and complete it according to the original design, have been supplied by subscriptions from all parts of Germany. The work of renovation began in 1823, and in 1842 the foundation-stone of the new part was laid. The naves, aisles, and transepts were opened in 1848; the magnificent south portal was completed in 1859; in 1860 the iron central *fleche* was added; and with the exception of the western spires, the church was completed in 1863. The spires, the crown of the edifice, were finished in 1880, and on October 15 the completion of the work was celebrated before the Emperor William I. The body of the church measures 440 feet in length, and 240 feet in breadth; the spires rise 515 feet above the pavement of the nave. Since 1823, upwards of £1,000,000 has been expended on the building; the total cost of the whole is estimated at £2,000,000. For the 'Kaiserglocke,' see BELL. Among the chief secular buildings of Cologne are the town-house, begun in the 14th century upon Roman foundations; the Gürzenich (1441-52), the finest secular Gothic erection in Cologne, a public banqueting-hall, now containing the exchange; the modern law-courts; and the Wallraf-Richartz Museum, containing a good collection of paintings.

The educational and benevolent institutions of Cologne are numerous and well equipped. The town has recently acquired a high reputation for music. The situation of Cologne is extremely favourable for commerce. Various branches of manufacture are carried on, of which the chief are the making of beet-sugar, tobacco, glue, carpets, soap, leather, furniture, pianos, chemicals, and spirits of wine, besides the characteristic manufacture of Eau-de-Cologne (q.v.). In 1886, 4859 craft entered, and 3190 cleared, the port of Cologne. Cologne has extensive and important railway connections.—The city was founded by the Ubii, about 37 B.C., and was at first called *Ubiorum oppidum*;

included in Austrasia; and by a treaty in 870, it was united to the German empire. It entered the league of the Hanse towns in 1201, and contended with Lübeck for the first rank. The merchants of Cologne carried on commerce far and wide, and had warehouses in London, near the Guildhall. Cologne was at a very early period the seat of a bishopric, which was elevated, at the end of the 8th century, into an archbishopric. The archbishops acquired considerable territories, some of them distinguishing themselves as politicians and warriors. They took their place amongst the princes and electors of the empire, but were involved in a protracted contest with the citizens of Cologne, who asserted against them the independence of the city; and the archiepiscopal resi-

dence was therefore removed to Bonn. The archbishopric was secularised in 1801, when the city also lost its independence, and the congress of Vienna did not attempt to restore to it its former character, but assigned the whole territories to Prussia. The archbishop, therefore, has not now the political rights and power that belonged to his predecessors.

Colombia, a republic occupying the north-west corner of the South American continent, and including also the Isthmus of Panamá. Its limits were officially stated in 1887 as 12° 25' N.—5° 8' S. lat., and 70° 40'—82° 40' W. long., and its area was estimated at 513,938 sq. miles (nearly as large as Great Britain, France, and Spain together), exclusive of most of its hundreds of islands and keys, which stretch as far north as the Mosquito coast. The population amounts to about 4,000,000, including some 200,000 uncivilised Indians who inhabit the remote forests. The situation of Colombia, washed by two oceans, with a total coast-line of nearly 3000 miles, possessing all along the Atlantic shore and on the Pacific side of Panamá commodious bays and lagoons, and with several fair harbours even on the less favoured coast to the south, presents great commercial possibilities, which should be increased by the opening of the canal from Colón to Panamá through the north-west department. The surface of the country is extremely varied, with lofty mountains in the west, and vast plains in the east scarcely above the level of the sea. For the mountains, see ANDES. This system spreads out in three great ranges, like the rays of a fan, from the extensive plateau of Pasto in the south-west; thus forming valleys running from north to south parallel to the three chains, except where disproportionate activity of the volcanic forces has caused an upheaval of the country near them. The fundamental formations of the country are igneous and metamorphic, and everywhere are traces of the disturbances (still not unfrequent in the form of earthquakes) that have

upheaved plateaus and opened fractures that now mark the courses of the principal rivers. Of the sections outside the main Cordilleras, the principal are the Sierra Nevada de Santa Marta, in the north, and the low Baudo range, along the north-west coast, which extends into Panamá. From the Central Cordillera descend the two principal rivers of Colombia, the Magdalena and its tributary the Cauca, which flow north into the Caribbean Sea, besides several affluents of the Amazon in the east, and the Patía, which forces its way to the Pacific, through a gorge between cliffs 10,000 to 12,000 feet high, and forms the only notable break in the long wall of the Western Cordillera from Darien to Patagonia. The Eastern Cordillera, by far the largest chain, consists of a series of extensive tablelands, cool and healthy, where the white race flourishes as vigorously as in Europe. This temperate region is the most thickly populated portion of the republic; and on one of its plateaus, at an elevation of 8694 feet, stands the capital, Bogotá (q.v.). Eastward from this Cordillera stretch vast *llanos* or plains, through which flow the Meta, the Guaviare, and other tributaries of the Orinoco. Besides these, the chief rivers are the San Juan (navigable 150 miles), on the Pacific coast; the Atrato (q.v.) and Zulía (150 miles), flowing north; the Arauca (600), which, as well as the Meta (700) and Guaviare (850), feeds the Orinoco; and the Caquetá (1350), the Putumayo (1100), and the Napo (750), tributaries of the Amazon. The lakes are unimportant.

Climate and Productions.—In the course of one day's journey, the traveller may experience in this country all the climates of the world; perpetual snows cover the summits of the Cordilleras, while the valleys are smothered in the rich vegetation of the tropics. The mean temperature ranges from 32° to 82°, according to the elevation. The climate of Panamá is notoriously unwholesome, and in some parts of Bolívar and Magdalena, in the north, marsh fevers abound. The rainy season falls from November to April, except among the low-lying forests of the south-east, where the rainfall is distributed throughout the year, and in the Chocó coast district of the north-west, where, shut in from the north-east winds, the heavy atmosphere hangs motionless, and mists and torrents of rain alternate. Colombia naturally yields a variety of productions corresponding to this great diversity of climate and of elevation. The hot region, extending to an elevation of about 3200 feet, produces in abundance rice, cacao, sugar-cane, bananas, yams, tobacco, indigo, cotton, caoutchouc, vegetable ivory, and many medicinal plants; and the forests, with their tagua and other stately palms, their rare balsamic resins and valuable dyewoods, are ablaze with flowers and creepers, and steeped in the perfume of the delicate vanilla orchid. In the temperate zone, from 3200 to 8500 feet above the sea, many of these plants are equally common, but the cocoa-nut palm gives place to the oak, the encenillo, groups of laurels, and arborescent ferns, and here flourish the coffee plant, the odorous Cherimoya (q.v.) and curibano, the fig, and the cinchona-tree. The Wax-palm (q.v.) extends beyond this region, and is found at a height of nearly 11,000 feet, and large crops of potatoes, grain, and leguminous plants are raised in the cold region; but from 10,000 feet rises the bleak páramo, with its scanty vegetation, ending in lichens at the snow-line. The fauna of Colombia is very extensive. Both coasts abound with turtles and pearl-oysters; the rivers swarm with fish and alligators, and on their marshy banks the capybara is found; the forests are the haunt of the tapir, armadillo, cavy, opossum, and deer, and during the day are alive with monkeys

(of which no less than seventeen species are common), squirrels, paroquets, and numerous bright-plumaged birds, whose notes give place at night to the plaintive cry of the sloth. Beasts of prey are the jaguar, puma, ocelot, margay, and bear. The boa and numerous other snakes are common, but venomous serpents cease at an elevation of 6000 feet, the centipede and the chigoe are not met beyond 9850 feet, while the plague of mosquitoes and ants, and of other more dangerous insects, is mainly confined to the lowlands. In the northern departments, and in the immense *llanos* of the east, great herds of cattle, descended from those imported by the Spaniards, are reared; in the central districts, shorthorns and other English, Dutch, and Norman cattle and horses have been introduced, and are largely raised throughout the temperate zone. Fish life ceases in the lakes at 13,000 feet; and in the solitudes above, the condor dwells alone. In minerals the country is exceedingly rich, although its scanty population, their poverty, and the absence of roads have combined to limit the exploitation of the precious metals. Nevertheless, in 1887, claims were presented to 751 mines in Antioquia; and from this department alone over £400,000 worth of gold is annually exported. The department of Tolima is the richest in silver. It is estimated that gold to the value of £125,000,000, and silver to the value of nearly £7,000,000, have been exported since the 16th century; and over 95 per cent. of this ore has been found west of the Magdalena. Iron, copper, lead, coal, sulphur, zinc, antimony, arsenic, cinnabar, rock-salt, crystal, granite, marble, lime, gypsum, jet, amethysts, rubies, porphyry, and jasper are also found; while much of the world's platinum is obtained from the upper San Juan, and the principal source of the finest emeralds is at Muzo in Boyacá, although there are other mines near Nemocon, in Cundinamarca.

Commerce, Finance, &c.—The only industries common to all the departments of Colombia are agriculture and the rearing of cattle. Coarse cloth fabrics for the inland trade are manufactured to some extent in Santander and Boyacá, and chinaware and cardboard in Antioquia; also soap, matches, and candles are made in Bogotá, and there are two foundries and a shoe factory in Cundinamarca; but straw-hats, known abroad by the name of Panamá, although they are made only in certain parts of Tolima, Antioquia, and Santander, are perhaps the only manufactured article exported from the country. The transit trade across the Isthmus of Panamá, valued at £15,000,000 per annum, is of far more consequence than the direct commerce. The foreign trade proper is mainly with Great Britain and the United States. The imports are mostly food-stuffs, textiles, machinery, and iron-ware; the exports, coffee, gold, silver, and other ores, caoutchouc, ivory-nuts, divi-divi, tobacco, cacao, cotton, cinchona, cattle, balsams, timber and dyewoods, hides and wool. The average annual value of imports in the period 1875-84 was \$9,662,806, of exports, \$13,584,890; in 1886 the value of imports was \$6,726,992, and of exports, \$13,032,278; but it is difficult to reduce these figures to British currency, for although the dollar has a nominal value of four shillings, the rate of exchange has since 1878 varied between five and a half and nine dollars to the pound sterling. The nation has for some years been undergoing a severe financial crisis. For the fiscal year 1888-89 the expenditure was estimated at \$23,852,806, and the revenue at \$18,178,700, showing a deficit of \$5,679,106; in 1888 the internal debt, floating and consolidated, amounted

to \$29,605,562, the foreign debt was calculated at \$13,435,178, and \$10,129,527 of government paper-money was in circulation. There appears, however, some reason to expect that the measures adopted to meet the nation's liabilities may prove effectual, and the present financial condition of the republic is said to be comparatively hopeful. For the rest, the government can only look to rigid economy and the development of its rich mines, which it is endeavouring to encourage to the utmost, for relief from its embarrassments. All enterprise, however, is sadly hampered by the difficulty of communication. The Magdalena and the other great streams are the principal arteries of commerce, and a good deal of steamer traffic is carried on; but, besides that of Panamá, there were in 1888 only six railways open for traffic, with a total length of 215 miles, although several others were expected to be completed shortly. The telegraph system has 2357 miles of lines, and this and the postal service (including a parcel post with Great Britain since 1888) are worked as efficiently as the condition of the country will permit. For the railway, canal, and other information as to the Isthmus, see the article PANAMA.

Population.—The chief aborigines of the country, the *Chibchas* or *Muyscas*, who inhabited the plateau of Bogotá, ranked among the nations of the New World second to the Aztecs and Peruvians alone. They worshipped the sun, had a calendar, and a government closely resembling that of Japan, lived in communes, were industrious farmers, and dressed in garments of cotton. Their rich, beautiful language has been forgotten by their descendants, but is preserved in a grammar published at Madrid by the Dominican missionary, Bernardo de Lugo, in 1619. The rest of the country was occupied by a great number of tribes, with as many dialects as divisions, sinking from the grade of the *Chibchas* to the naked savages of the plains, who were little above the level of the brutes they hunted. Some of the intermediate races, while understanding Spanish, have preserved their primitive speech; the uncivilised Indians are now mostly confined to the eastern plains, the northern portion of Magdalena, and the district of Darien and the Atrato. The pure whites form about a fifth of the entire population, and the Indian half-breeds more than half; there are now scarcely any pure negroes left in the country, but the mulattoes and *zambos*, resulting respectively from the union of negroes with whites and Indians, exceed a sixth of the whole. Slavery was finally abolished in 1852, and in 1870 a system of compulsory education was adopted which has on the whole proved successful. Parochial, secondary, normal, and technical schools are now within general reach, and all the departments boast universities of more or less efficiency, except Magdalena, Tolima, and Panamá. Journalism is largely represented in most of the large towns; and at the capital a considerable number of books are published every year. The state church is the Roman Catholic, which in the management of its own affairs is independent of the civil authority; religious orders were suppressed in 1863, and toleration in matters of religion is guaranteed; but, by the terms of a concordat entered into with the holy see in 1888, in the universities and all educational establishments public instruction is directed in conformity with the dogmas of the Roman Catholic Church, religion is one of the obligatory subjects of study, and diocesans are empowered to suspend teachers or professors who neglect or disobey this order.

History.—The northern coasts of Colombia were visited by Ojeda and Amerigo Vespucci in 1499, and afterwards by Bastidas; in 1502 Columbus

explored part of the country, and endeavoured to found on the Isthmus of Panamá the first Spanish colony on the American mainland. In 1513 Balboa (q.v.) discovered the Pacific, and Pizarro and Almagro sailed along the western coast of Colombia on their way to Peru in 1526. Ten years later Jimenez de Quesada broke the power of the Muyscan empire, and the *Nuevo Reino de Granada* was formed. As the country was opened up, the Indians sank, in spite of legislation designed for their protection, to the condition of serfs, and the policy of the crown, aided by the Inquisition, which was introduced in 1571, put an end to the democratic institutions of the early settlers. The region was administered by the Council of the Indies; nearly all posts were sold to Spanish speculators, who recouped themselves at the expense of the colonists; and even the commerce of the new possessions was granted as a monopoly to the merchants of Seville. The country formed a presidency (except during the years 1718–24) from 1564 to 1739, a period memorable for the disastrous descents of Drake, Morgan, Dampier, and others on the coast towns; it was then raised to a viceroyalty, which lasted until the war of independence.

On the 20th July 1810 the colony shook off the yoke of the mother-country, and entered upon the long struggle which ended in the election of Bolívar (q.v.) to the presidency of the *Republic of Colombia*, a term which, like the viceroyalty, embraced all that now belongs to Venezuela, Colombia, and Ecuador. Independently of the singular difficulties of communication, and of the resulting absence of anything like natural unity, this unwieldy state contained from the beginning the germs of its own dissolution in the national character of its inhabitants. So long as union was necessary to meet external dangers, it maintained an imposing attitude in the eyes of the world; but gradually sectional interests and political jealousies did their work, and in 1831 the ill-assorted elements of the confederation were separated for ever. What is now Colombia was then formed under the title of the *Republic of New Granada*; but in 1861 a fresh civil war led to the establishment of the *United States of Colombia*. In 1863 a constitution was adopted, based on that of the United States of America, with a president elected for two years; but this proved altogether unsuited to the Colombians, and, after twenty years' trial, brought about the revolution of 1884–85. In 1886 a fresh constitution was adopted for the new *Republic of Colombia*, placing the central authority in the strengthened hands of the federal government, and reducing the nine former self-governing states of Antioquia, Bolívar, Boyacá, Cauca, Cundinamarca, Magdalena, Panamá, Santander, and Tolima to subordinate departments, which still, however, retain the management of their own finances. The executive authority is vested in a president, whose term is extended to six years, assisted by a vice-president, seven ministers, and a council of state; and the legislative power rests with a senate and House of Representatives. Capital punishment has been again established, and the members of the supreme court of justice are made immovable. The strength of the army is fixed at 6500 in time of peace, but in case of war the executive can raise this as circumstances may require.

Hall, *Colombia* (Philadelphia, 1871); Esquerro, *Diccionario Geográfico de Colombia* (Bogotá, 1879); Pereira, *Los Estados-Unidos de Colombia* (Paris, 1883); Perez, *Geografía General* (Bogotá, 1883); Etienne, *Nouvelle Grenade* (Geneva, 1887); Dr W. Sievers, *Feise in der Sierra Nevada de Santa Marta* (Leip. 1887); and the same author's *Cordillere von*

Mérida (Vienna, 1888) contains some notes on eastern Santander. See also the *Description* published by the Colombian government in 1887, with the supplement on the trade with Spain, published at Barcelona in 1888; F. Bianconi's *Notice Descriptive et Carte Commerciale* (Paris, 1888); and papers by F. A. A. Simons (1879, '81, '85) and R. B. White (1883) in the *Proceedings of the Royal Geographical Society*.

Colombo, the capital of Ceylon, is situated on the western side of the island. Since the construction of the great breakwater begun in 1875 (see **BREAKWATER**), the harbour has been greatly improved, and commerce has largely increased; Colombo having superseded Galle as a Coaling Station (q.v.) for large steamers. It contains the government offices, is the seat of an Anglican bishop, and is an important centre of missionary enterprise. Among the chief buildings are the government house, court-house, town-hall, asylum, St Thomas's College, and Wesley College. The fortifications of Colombo were constructed by the Dutch. Colpetty, a beautiful suburb, shaded by groves of the cocoa-nut palm, is a favourite retreat. The humble, mud-constructed dwellings of the Dutch, Portuguese, Eurasians, Singhalese, Tamils, Moors, and Malays are outside the city walls. The *pettah* or Black Town, the only ancient quarter, extends to the river Kalany-ganga. Pop. (1871) 100,238; (1881) 110,502. Colombo is connected with Kandy by railway. The early name of Colombo, *Kalan-totta*, the 'Kalany Ferry,' the Moors corrupted into Kalambu, and by this designation it was described by Ibn Batuta about 1340 A.D. as the finest city of Serendib. The Portuguese, who fortified it 1517 A.D., wrote the name Colombo, in honour of Christopher Columbus. The Dutch succeeded to the Portuguese, and Colombo was taken by the British, 16th February 1796. See **CEYLON**.

Colon. See **ASPINWALL**.

Colon, that portion of the large intestine which extends from the Cæcum (q.v.) to the rectum, which is the terminal portion of the intestinal canal. See **INTESTINES**.

Colonel (from the Italian *colonnello*, the 'leader of a column') is the grade of officer next below that of general. The chief officer of an English regiment at one time bore the title of captain, but since 1588 that of colonel has been substituted. In the British army, except in the Artillery and Engineers, the office of regimental colonel, as distinct from a colonel on the staff, is a sinecure, the commander of the infantry battalion or cavalry regiment being the lieutenant-colonel. Regimental colonels are general officers, who have had a regiment 'given to them,' as it is called, as a reward for long service, and virtually as a retirement. The pay, except in the Guards (where it is higher), is £1000 a year. In 1888 it was decided to discontinue these appointments as soon as those who have a vested right to succeed to them have been satisfied, and it has been decided that no officer shall obtain the rank of colonel except by Brevet (q.v.) for distinguished conduct, or on being selected for certain appointments carrying with them that rank; such as aide-de-camp to the sovereign, assistant-adjutant general, and commander of a regimental district. See **COMMISSIONS, ARMY**. In the German, Austrian, and Russian armies, where the regiments are very large, the colonelcies are mostly honorary posts, held by royal and other distinguished personages.

Colonia, a department of Uruguay, on the Plata, below the Uruguay River. The uplands are barren, but in the fertile valleys and plains are numerous European colonies, engaged in agriculture and stock-raising. Area, 2185 sq. m.; pop. (1885) 33,209. The capital, Colonia del Sacramento, on

the Plata, about 100 miles above Monte Video, has a good harbour, a dock for vessels of 1000 tons, ruined fortifications, and some 1500 inhabitants.

Colonial Animals, organisms which cannot be fairly regarded as unities, but consist of numerous more or less similar individuals united in a common life. Among the usually single-celled simplest animals or Protozoa, loose colonies not unfrequently occur, and are of not a little importance as suggestions of the bridge between the single-celled and many-celled animals. Such colonies arise when the original cell, instead of reproducing discontinuously, retains its daughter-cells in union with itself or with one another, just like the egg-cell of a higher animal. By sacrifice of individuality at the epoch of reproduction, a higher unity is formed. In the same way a simple cup-shaped sponge, by continuous budding, forms a colony of similar forms, which may possess more or less distinct individuality. The common fresh-water *Hydra*, to mount a step higher, buds off daughter *Hydræ*, which remain for a while connected with the parent organism, and make it temporarily colonial. This becomes constant in the myriad colonies of hydra-like forms which are known as Zoophytes, or Hydroids (q.v.). The same formation of colonies is well illustrated in the higher polyps of the sea-anemone type, where in dead-men's fingers and in most corals, compound or colonial organisms are beautifully illustrated. Some jellyfish-like or medusoid types also become compound, and lead on to the order Siphonophora, where, as in the Portuguese man-of-war (*Physalia*) or in *Velella*, the occurrence of compound forms is a constant character. But in this last case a further step has been made, for the individuals not only share a common nutritive life, but are bound together in a more intimate way into a true unity of a higher order. Among simple worm-like forms, chains of individuals are occasionally formed, as in *Catenula*, and these point to the probable origin of the higher or segmented worms which consist of a series of similar 'joints.' Even among the higher worms, temporary compound forms occasionally occur, as in the fresh-water *Nais* or the marine *Syllis*. The Polyzoa afford good illustration of colonial life as an almost constant character of a class. Finally, passing beyond the limit of invertebrate animals, we find the last examples of true colonial organisms in the Ascidians (q.v.) or Tunicata. The occasional development of double or multiple forms from a single ovum is among higher animals the only suggestion of compound organisms.

From the above illustrations a few general conclusions may be drawn. The process of asexual budding, which leads to the formation of compound organisms, is commonest in relatively passive vegetative animals, like sponges, hydroids, corals, polyzoa, and ascidians, and is an expression of their general physiological constitution. When the colonial organism is free-living, as in Siphonophora and some Tunicata, the individual members are more closely knit together, and the colony is more perfectly integrated. As above suggested, some colonial forms are of importance as illustrating in loose union an order of individuality, which in higher types becomes more firmly unified. We first find loose 'aggregates;' at a higher level these become 'integrated.' The loose colonies of some medusoid types are thus succeeded by more perfectly integrated forms in the Siphonophora. Finally, colonial organisms are of the highest physiological interest in illustrating division of labour. In a compound organism the internal and external conditions of life are not uniform for all the members; certain 'persons,' as the individuals are technically called, exhibit the predominance of one function, and others of another;

the differences in function thus started bring about more or less marked difference of structure as its consequence; and thus division of labour and 'polymorphism' or difference in form are established. See Perrier, *Les Colonies Animales* (1882).

Colonial Corps were regiments of the regular British army, paid out of imperial revenues, and located in the various colonies where they were formed. The following corps, and numbers were provided for in the Army Estimates for 1860-61:

Three West India Regiments (afterwards raised to five).....	3420	Negro.
Newfoundland Veterans.....	220	British.
Ceylon Rifles.....	1585	Native.
" Invalids.....	163	Native.
Cape Mounted Rifles.....	1084	Boers and natives.
Malta Fencibles.....	638	Native.
Canadian Rifles.....	1100	British.
St Helena Regiment.....	433	"
Gold Coast Artillery.....	351	Negro.
Falkland Islands Company.....	37	British.
African Artillerymen.....	64	Negro.
Hong-kong Gunners.....	88	Lascars.

All the officers were British, except those of the Malta Fencibles. The Cape corps were mounted infantry. Though maintained out of imperial revenue, these corps were not available for the general defence of the empire, and accordingly have been gradually disbanded, their places in the colonies being supplied by levies of local militia. There still exist, besides African commissariat, ordnance store, and medical staff corps, one West India Regiment of two battalions, the Malta Fencibles, one company of Gun Lascars in Ceylon, and another at Hong-kong.

Colonial Office. See SECRETARY OF STATE.

Colonial System, also called COMMERCIAL SYSTEM, a name for the theory long acted on by European nations, that their settlements abroad were to be treated as proprietary domains, exploited for the benefit of the mother-country, which did everything it could to import their produce as cheaply as possible, and encourage them to a large consumption of home manufactures. The system was carried to its furthest extent by Spain. See COLONY, FREE TRADE, MONOPOLY, NAVIGATION LAWS, SPAIN, UNITED STATES.

Colonisation Society. See LIBERIA.

Colonna, CAPE (ancient *Sunium Promontorium*), a headland of Greece, forming the south-most point of Attica, and crowned by the ruins of a temple of Minerva, thirteen of whose white marble columns, from which the cape derives its modern name, are still standing.

Colonna, a celebrated Roman family, which took its name from a village among the Alban Hills, 12 miles ESE. of Rome, and which, from its numerous castles, vast estates, and crowds of clients, enjoyed a powerful influence from the 11th to the 16th century. From it have sprung a pope (Martin V., q.v.), several cardinals, generals, statesmen, and noted scholars, and VITTORIA COLONNA, the most celebrated poetess of Italy. She was the daughter of Fabrizio Colonna, Constable of Naples, at whose estate of Marino she was born in 1490. When four years old, she was betrothed to a boy of the same age, Ferrante d'Avalos, son of the Marchese di Pescara; at seventeen they were married. After her husband's death in the battle of Pavia (1525), Vittoria Colonna found her chief consolation in solitude and the cultivation of her poetical genius. During seven years of her widowhood she resided alternately at Naples and Ischia, and then removed to the convent of Orvieto, afterwards to that of Viterbo. In her later years she left the convent, and resided in Rome, where she died in February 1547. She was the loved friend of Michael Angelo, admired by Ariosto

(see canto xxxvii. of the *Orlando*), and the intimate associate of the reforming party at the papal court. Her poems belong chiefly to the period following her husband's death, and are remarkable for truth of sentiment and enlightened piety. They were first published at Parma in 1538; the most perfect edition is that of Ercole Visconti (Rom. 1840). See Mrs H. Roscoe's *Vittoria Colonna, her Life and Poems* (Lond. 1868), and a study by the Hon. Alethea Lawley (1888).

The family is still distinguished in Italy, three of its four lines being princely. The Colonna palace, situated at the base of the Quirinal (Rome), is celebrated for its splendid gallery and treasures of art.

Colonna, GIOVANNI PAOLO, composer, born about 1640, either at Brescia or Bologna, became principal of the musical academy at Bologna. Of some 44 works, nearly all were for the church; his one opera, *Amilcare*, was first performed in 1693. He died 28th November 1695.

Colonsay and Oronsay, two of the Argyllshire Hebrides, 16 miles NNW. of Port Askaig in Islay, separated from each other by a sound, 100 yards wide, and dry at low water. Colonsay, which rises to a height of 493 feet, is 16 sq. m. in area; Oronsay, only 3. On the latter are a sculptured cross and a 14th-century Austin priory, with some curious effigies; whilst in the former are standing stones, a bone cave, Colonsay House (1722), and an obelisk to the memory of the lawyer, Duncan McNeill, Lord Colonsay (1794-1874). Pop. (1851) 933; (1881) 397, of whom 10 were in Oronsay.

Colony (Lat. *colonia*), a name somewhat vaguely applied to the foreign dependencies of a state. In accordance with its etymology (*colonus*, 'cultivator'), a Roman *colonia* ought to have been an agricultural community; but as a matter of fact it was a military settlement, urban rather than rural, planted in subject territory. It was essential that the colonists should remain citizens, who thus both extended and knit together the power of Rome. The name survives to this day in Cologne and Lincoln. The Greek colony (*apoikia*) consisted of a band of emigrants, who were impelled by political dissension or some similar cause to seek a new home beyond the sea, and who were connected with their mother-city (*metropolis*) by no tie stronger than that of sentiment. According to the legend enshrined by Virgil in his *Æneid*, Rome itself was a colony, in the Greek sense, of Troy. No Greek colonists penetrated far inland; but the shores of Asia Minor, Sicily, Southern Italy, and even the Crimea, were at an early date fringed with commercial settlements, many of which surpassed in wealth the cities of Greece proper. The Phœnicians, who preceded the Greeks as the traders of the Old World, were not a colonising race. Carthage, indeed, was an offshoot from Tyre; but the wide empire of Carthage was based partly upon conquest, and partly upon a system of trading factories.

Colonisation is an incident of a comparatively settled state of society. The vast land migrations which have so profoundly affected the populations of Europe and Asia belong to a different category. Thus it happens that, after the break-up of the Roman empire, the very idea of a colony is not heard again until the great outburst of maritime enterprise in the 16th century. Spain and Portugal led the way, followed by Holland, England, and France. Love of adventure, thirst for gold, the missionary spirit—all combined to attract the energies of Europe, set free by the Renaissance, to the New World and to the farther East. The long and bitter struggle for territorial aggrandisement beyond the seas went on with various vicissitudes until, at the close of the 18th

century, the foreign possessions of the several states of Europe stood pretty much as they do now. Out of her once mighty empire, Portugal retained only a few petty settlements in India, an indeterminate authority over long strips on both coasts of Africa, and Brazil, which has since become independent under a scion of the house of Braganza. Spain has lost Southern and Central America within the present century; but she keeps her hold of Cuba and Porto Rico in the West Indies, and of the Philippine and Caroline groups of islands in the remote eastern seas. Holland, having been deprived by England of Ceylon and the Cape, still draws a rich tribute from Java and the adjoining Spice Islands. France, which entered last upon the struggle, has suffered most severely of all, as the result of the fortune of war with England. At one time it seemed as if half North America, and perhaps all India, would become French. But the twin stars of Wolfe and Clive influenced the fate of two continents. The acquisition of Algeria dates from 1830; and within the last decade France has again pushed forward in Tunis, Tonquin, and Madagascar. Italy has no foreign possessions except the port of Massowah on the African shore of the Red Sea; and those which Germany has recently acquired with so much eagerness, in Africa and in New Guinea and the adjoining islands, must be regarded rather as possible outlets for trade than as true colonies. The surplus population of Germany will doubtless continue to pour into the western states of North America, just as the Italians and Basques will continue to be attracted to the River Plate.

After this brief survey of the foreign possessions of continental states, we pass on to those of Britain, which alike in area, in population, and in promise for the future, surpass tenfold all the rest put together. If it be permissible, on historical grounds, to regard the United States as one with Britain, it may be said that the story of modern colonisation is the story of the expansion of the Anglo-Saxon race. In North America, Australasia, and South Africa, that race is already in occupation of the only large tracts of uninhabited territory where white men can work and multiply. In India, England owns the most fertile and most easily governed of tropical countries; while her minor possessions are dotted over every land and sea. These advantages abroad—gained by the valour of her children, who have known how to make the most of their good fortune—are maintained by a teeming population at home, superabundant capital, and maritime supremacy. Above all, it should ever be remembered that this great colonial empire, as it was won with no deliberate plan of aggression, so it is preserved solely through the conscious recognition of mutual rights and duties. Even in India, British rule exists by the consent of the natives and for their benefit; while the autonomous colonies of Australia are as free from British interference and as loyal to the British name as the Channel Islands or Man.

The colonial empire of England is as varied in its composition as it is vast in its extent. In the political sense, it ought to include every foreign possession or dependency of the crown. It is only by an accident of administration that India is the charge of a distinct secretary of state, that some indeterminate protectorates (such as that of the Niger) are controlled through the Foreign Office, and that the island of Ascension is borne as a ship on the books of the Admiralty. So again, the colonies proper—i.e. those in subordination to the Colonial Secretary—vary in character from a settled country, with a civilisation more than a century old, like Lower Canada, to an unexplored wilderness of savages, like New Guinea; from the continent of

Australia to the rock of Gibraltar; from Hong-kong, the emporium of Chinese trade, to Heligoland, the favourite watering-place of Hamburgers. Adopting another principle of division, the colonies may be classified according to the modes by which they were acquired: (1) as conquered by force of arms or ceded by an independent power; (2) as occupied by settlers, where no rights were recognised in the aboriginal inhabitants. The former class would comprise the Cape and Hong-kong, the latter class Australia and British Columbia. The classification adopted by the colonial office is based upon differences of administration, as follows: (1) Crown colonies, in which the crown has the entire control of legislation, while the administration is carried on by public officers under the control of the home government. Of this class examples are Gibraltar, Ceylon, and Jamaica. (2) Colonies possessing representative institutions, but not responsible government, in which the crown has no more than a veto on legislation, but the home government retains the control of public officers. In this class are Natal, Western Australia, and Barbadoes. (3) Colonies possessing representative institutions and responsible government, in which the crown has only a veto on legislation, and the home government has no control over any public officer except the governor. This class comprises Canada, Newfoundland, the Cape, and the Australasian group. According to the *Colonial Office List* for 1888, the total area of all the colonies and dependencies (excluding India) is 7,475,896 sq. m., with an estimated population of 18,346,614. Of these totals the nine self-governing colonies possess between them 5,884,020 sq. m. and 9,413,855 souls. (For Cyprus, North Borneo, the Niger Protectorate, and all British dependencies, see GREAT BRITAIN.)

From an historical point of view, the expansion of the Anglo-Saxon race divides itself into three periods: (1) The 17th century, when the first beginnings were made, in rivalry with other European states which had taken the lead; (2) the close of the 18th century, when, as a result of the French wars and the command of the sea, Britain had won a preponderant position, despite the loss of the United States; (3) the 19th century, which has been a continuous period of growth and consolidation. Newfoundland boasts herself the premier British colony, having been annexed by the ill-fated Sir Humphrey Gilbert in 1583. The East India Company was incorporated in 1600; the first permanent settlement of Virginia dates from 1607; the historic *Mayflower* sailed from Plymouth to New England in 1620; Barbadoes was occupied first of the islands in the West Indies in 1625. The second period—a period of war—begins with the capture of Gibraltar in 1704; its decisive point was reached at the peace of 1763, when the French yielded alike in Canada and in India; and it culminated in the Napoleonic war, when Malta, Mauritius, and many West Indian islands were captured from France, and Ceylon and the Cape from Holland, then a French dependency. The last period, which is almost co-extensive with the reign of Victoria, has witnessed the consolidation of India under the crown; the marvellous development of Australia under the stimulus of gold discoveries; the erection of Canada into a dominion of confederated provinces; the extension of British influence throughout South Africa; the commercial growth of Hong-kong and Singapore; and the gradual advance of the British flag over new protectorates and isolated Coaling Stations (q.v.). It is estimated that the population of the colonies has multiplied more than fourfold since 1837, while the external trade has multiplied nearly ninefold.

Though colonisation is by no means synonymous

with emigration, it is perhaps natural for the mother-country to regard her colonies primarily as affording an outlet for her own surplus population. As a matter of fact, the inhabitants of Australia are almost exclusively British; so, too, are the inhabitants of Canada, with the notable exception of the province of Quebec, which remains to this day thoroughly French in language, in religion, and in sentiment. At the Cape, again, the descendants of the Dutch settlers still form about one-half of the whole population. But when the statistics of emigration are looked into, it will be found that the United States prove much more attractive than all the colonies added together. In 1887 the total number of emigrants from the United Kingdom, of British and Irish origin, amounted to 281,487, of whom as many as 72 per cent. selected the United States; while only 34,183, or 12 per cent., went to the Australasian colonies, and 32,025, or 11 per cent., to British North America. Nor was that year at all exceptional. The census returns of the United States in 1880 show 2,772,169 persons born in the United Kingdom; while the corresponding figures are 912,935 for all the Australasian colonies, and 470,092 for Canada; total 1,383,027, or less than half the number in the United States. The home government has taken no measures to direct emigration to the colonies, beyond establishing in 1886 an Emigrants' Information Office in London, for the collection and publication of trustworthy information. Queensland alone gives free passages. Natal and Western Australia give assisted passages to farm labourers and domestic servants. See EMIGRATION.

The tie between the mother-country and the colonies is more manifest in the case of commerce. The old practice has long ago been abandoned of compelling the colonies to trade only with the mother-country; and those of them that are self-governing have even been allowed to impose protective tariffs against British manufactures. But, nevertheless, the trade of Britain with her colonial possessions has maintained itself more steadily than her trade with the rest of the world. During the fourteen years from 1872 to 1886, the imports into the United Kingdom from British possessions (including India), notwithstanding the fall in value, increased from £79,372,853 to £81,884,043, while the proportion of these imports to the total imports rose from 22 to 23 per cent. In the same period the exports to British possessions increased from £65,609,212 to £82,067,711, while their proportion to the total exports rose from 21 to 31 per cent. Taking the returns from colonial sources, 42 per cent. of the aggregate trade of all the colonies in 1886 was conducted with the mother-country. Such, expressed in dry figures, is the meaning of the maxim that 'trade follows the flag.' Though statistics are not so readily obtainable, there can be no doubt that the investment of British capital in the colonies, and the consequent return of interest, forms a bond of a still closer nature than the interchange of commodities. In 1886 the aggregate public debt of all the colonies (excluding India) amounted to about 245 millions sterling.

The most interesting question that remains to be considered is the political relation between the colonies and the mother-country. Not so many years ago it was tacitly assumed that the grant of responsible government to the greater colonies implied the further concession of complete independence whenever the colonies should care to demand it. History seemed to afford support for no other conclusion. Quite apart from the case of the United States, it was argued that any form of political union was impracticable between members

of a state scattered over such immense distances and with such divergent interests. Above all, it was doubted whether the slender link existing could stand the strain of a great European war. What concern has Canada with Constantinople, or Australia with Afghanistan? But there were always some to whom such calculations appeared to be a base abandonment of England's historic place among nations; and the colonists themselves have always professed the most perfect loyalty to the British connection, exactly in proportion as they have been intrusted with autonomy in their own local affairs. Canadian *royaleurs* took a prominent part in Lord Wolseley's boat expedition up the Nile in 1884; and a battalion of 800 volunteers from New South Wales fought by the side of British soldiers round Suakin in 1885. The sense of distance has been largely obliterated by the marvellous progress of steam and electricity. The circumnavigation of the globe is now accomplished as easily and as frequently as was the grand tour in the 18th century. Many of the younger politicians make it part of their education to visit India, Australia, and Canada; the colonists, too, have ceased to be strangers in England—'home,' as they always call it, though born thousands of leagues away. In this connection the future historian will not think it beneath his dignity to record the beneficent influence of cricket. An English team first went to Australia in 1862; while Australian elevens have played on equal terms with the best cricketers of England in every alternate year since 1878. The increase of intercourse has brought with it an increase of mutual knowledge and of mutual respect. The holding of a great exhibition of colonial and Indian produce at South Kensington in 1886, and the plan of commemorating the jubilee of the Queen by an Imperial Institute, have given concrete expression to the feeling of solidarity that was everywhere growing. Few persons, either in England or in the colonies, would now be found to advocate the weakening, still less the severing, of the present political ties.

With regard to the scheme known as Imperial Confederation, less agreement is to be found. It may be suspected that many of its British supporters have been influenced chiefly by their greater dislike of separation; while in the colonies it has nowhere been received with enthusiasm. The essence of the scheme is that the existing parliament of Great Britain and Ireland should divest itself of its sovereignty in favour of a federal council, formed by election out of all the constituent parts of the empire. To this council would be delegated the initiative in foreign affairs, the power of treaty-making, the right of declaring war, with the control of the army and navy that necessarily follows therefrom. Putting aside the difficulties that would arise from the inequality of the colonies among themselves, it is easy to see that Britain must, for a long time to come, exercise the decisive pre-eminence in such a council.

In the meantime something has already been done, and more may be, to strengthen the position of the colonies in the English political system. Canada, the Australasian colonies, and the Cape, each have an agent-general resident in London, whose functions are steadily growing in dignity. It has become the custom for every new Colonial Secretary to invite the agents-general to a ceremonious reception on his appointment; they are consulted, either singly or collectively, in all matters affecting the colonies which they represent. It is not impossible that their status may ultimately develop into something intermediate in authority and honour between the council of the India Office and the *corps diplomatique*. The elastic powers of the Privy-council might easily be utilised

so as to constitute them (with other representatives for the crown colonies) into a committee for the general control of colonial affairs.

A still more important step forward was taken in 1887, when a conference was held in London, under the presidency of the Colonial Secretary, at which delegates specially appointed by all the colonies were present. Many of the subjects discussed were of a commercial or legal character; but a large measure of agreement was also arrived at with regard to the burning question of colonial defence. Broadly speaking, the self-governing colonies have undertaken to provide for their own defence by land by maintaining a trained force of a specified strength; while England will supply ships and guns for the protection of commerce and coaling stations. This agreement has been embodied, so far as the mother-country is concerned, in a statute passed in 1888. It is not to be expected that such conferences will become a permanent institution. They would form too severe a tax upon colonial politicians of the first rank. But the precedent is valuable as showing the mother-country consulting with her daughters in a family council. Whatever may come of Colonial Confederation, British statesmanship will have ere long to face the duty of reconciling local self-government with imperial unity; and the history of the Anglo-Saxon race encourages us to believe that the problem will not prove insoluble.

The colonies of the chief countries will be found under GREAT BRITAIN, FRANCE, GERMANY, SPAIN, &c. The following are some of the more important books on the subject: Heeren's *Manual of the Political System of Europe and its Colonies* (Eng. trans. in 2 vols. 1841); Sir G. Cornewall Lewis's *Essay on the Government of Dependencies* (1841); Herman Merivale's *Lectures on Colonisation* (1841-42; new ed. 1861); Sir C. W. Dilke's *Greater Britain* (1869); J. A. Doyle's *The American Colonies Previous to the Declaration of Independence* (1869); E. J. Payne's *History of European Colonies* (1877); *Colonies and Dependencies*, in the 'English Citizen' series (1883); J. R. Seeley's *The Expansion of England* (1885); J. A. Froude's *Occana* (1886), and *The English in the West Indies* (1888); the various Handbooks published in connection with the Colonial and Indian Exhibition (1886); and especially the volume entitled *Her Majesty's Colonies*, and the annual *Colonial Office List*, published by Messrs Harrison & Sons. Also see the articles on the various colonies.

Colophon, an Ionian city of Asia, about 9 miles N. of Ephesus, and near the sea-coast. The river Halesus, noted for the coolness of its water, flowed past it. It was the native city of Minnermus, the elegist, and claimed to be the birthplace of Homer. In its neighbourhood was the famous oracle of Apollo Clarius. The Greek proverb, 'to put the colophon to it,' meaning to terminate an affair, is explained by Strabo as arising from the belief that the cavalry of Colophon was so excellent that their *charge* always decided a battle. Hence, in old printed books, any device, or printer's name, or the place and year of printing, printed at the end, was called a *colophon* (see BOOK). It gave its name also to *colophony*, a kind of black resin, for which see ROSIN.

Coloquin'tida. See COLOCYNTH.

Colorado (Span. for 'red' or 'reddish'), a remarkable river of North America, formed in 39° 17' N. lat., 109° 50' W. long., by Copyright 1889 in U.S. the union of the Grand and Green by J. B. Lippincott Company. rivers. The Green River rises in Wyoming, U.S., and drains the south-west portion of that territory; it also receives affluents from Utah and the north-west angle of the state of Colorado. The Grand River rises in Colorado, where its more common name is the Gunnison. Its main tributaries in that state are the Bunkara, or Blue, and the Dolores. Below the junction of the

Green and Grand rivers the main affluent in Utah is the San Juan, which drains an interesting region in the south-west of Colorado and the north-west of New Mexico. In Arizona the main affluents are the Colorado Chiquito or Flax River, the Bill Williams, and the Rio Gila, all from the left. The only important affluent the Colorado receives from the right is the Rio Virgen. From the junction of the Grand and Green, the general course of the stream is to the south-west, through the southern part of Utah and the north-west of Arizona; and it afterwards separates Arizona from Nevada and California. The lower part of its course is in Mexican territory, where it flows into the north extremity of the Gulf of California. The most striking features of the Colorado basin are its dryness, and the deeply channelled surface of the greater part of the country. Almost every stream and water-course, and most of all the Colorado itself, has cut its way through stratum after stratum of rock, until now it flows, in a great part of its course, at the bottom of a deep trench or cañon.

Grand Cañon of the Colorado, looking up.
(From a Photograph by E. Baer, of Prescott, Arizona.)

The main stream for nearly 400 miles below the mouth of the Colorado Chiquito, thus makes its way through a great plateau, forming what is called the Grand Cañon of the Colorado, the most extensive and marvellous example of the kind anywhere known. The cañon-walls throughout the upper part of the great cañon are from 4000 to 7000 feet in height, and are often nearly perpendicular. At some points the walls on either side rise sheer from the water; at others there is a talus of fallen rock, or occasionally a strip of fertile soil, on one or both banks. This over-drained river basin has an area of 240,000 sq. m. Its former adaptedness

to the support of human life on a considerably greater scale than at present, seems to be evidenced by the presence of great numbers of abandoned and prehistoric dwellings, sometimes perched upon cliffs within some cañon, or on a high ridge or *mesa*, as if for protection from hostile attack. The Moqui towns in Arizona are still inhabited by interesting tribes of semi-civilised aborigines, no doubt relics of a race once very much more widely spread. The whole course of the river below the junction is about 900 miles; to its remotest sources it is 2000 miles. Navigation is possible for light-draught steamers for over 600 miles. At extreme high water, steamboats sometimes go up to the mouth of the Rio Virgen to load rock-salt. The lower portion of the river is visited at certain seasons by *boces*, or high tidal waves, a phenomenon to be seen in only a very few North American rivers. The non-tidal portion of the river is subject to vast and frequent changes of volume, and except where confined by cañon-walls, the river channel shifts to and fro in its sandy alluvial bed to a very remarkable degree. Navigation is much impeded by rocks and sand-bars.

COLORADO RIVER OF TEXAS rises by many head-streams in the south part of the Llaño Estacado, of North-west Texas. Its two main head-streams are the Concho or Salt Fork, and the Red or North Fork. The river takes a devious south-eastward course of 900 miles, and discharges its waters by two main outlets into Matagorda Bay. It is about 900 miles long, and its drainage area is put at 24,700 sq. m. Sand-bars at its mouth impede navigation. Steamboats have ascended the river as far as Austin, the capital of the state; but the stream is not much navigated. The basin of the river is in part very level, but in some parts of the course the banks are bold and bluff. The valley of the Colorado is fairly supplied with timber, and the soil is generally fertile; but the rains are much less abundant than in the river basins lying farther to the eastward. It is stated that this river was named Brazos by the Spanish colonists, and that the Colorado of the same settlers was what is now called the Brazos; the names having been misapplied or transposed in later times by mistake. The Colorado is the largest river wholly within the state of Texas, except only the Brazos.

Colorado, a state of the American Union, in 37°–41° N. lat., and 102°–109° W. long., traversed from north to south by ranges of the Rocky Mountains. It takes its name from the river Colorado, to the basin of which all the western slope of the state belongs—as the eastern to the Mississippi valley—while part of the south is drained by the Rio Grande and its head-streams. The area is 103,645 sq. m., or rather more than half the extent of France; so that Colorado ranks as fourth in area among the states, being surpassed in this regard by Texas, California, and Nevada alone. The vast ranges which traverse this region have mostly an approximate north and south direction, with many deviations. The high plains and overdrained *mesas* to the west are not clearly marked off from the mountain-region; and much of the western slope is actually mountainous. The eastern slope, which embraces about two-fifths of the whole state, is, apart from the foot-hills skirting the flank of the mountain-region, an open and comparatively treeless plain, with a surface singularly monotonous, and for the most part devoted to the pasturage of cattle and sheep, an interest which is of high importance in nearly all parts of Colorado. This level region averages 5000 feet in altitude, and its lowest point is 3000 feet above sea-level. The mountain-region contains many peaks exceeding 14,000 feet in height, the loftiest being Blanca

Peak (14,464 feet); while the summits exceeding 13,000 feet are stated to be more than one hundred in number. The mountains, notwithstanding their general parallelism, are greatly broken into short and variously named chains, there being no one ridge that can distinctly claim to rank everywhere as the main range of the system. Six passes cross mountain-ranges at points over 12,000 feet high; the Argentine Pass is 13,000 feet in altitude. Railways are led across many of these passes, and their construction through the valleys and cañons has called for many brilliant displays of engineering skill and boldness. A marked feature of the mountain-region is presented in the *parks*, or rich mountain-valleys, often very spacious, and generally bearing evidence of being the basins of lakes once extensive, but now nearly or quite dried up. The central mountain-region, with its parks, cañons, and hot springs, and its rich mineral deposits, has attracted most attention. The western part of the state is far less accessible and less developed, although its mineral wealth and the construction of railways have led to the settlement of some parts of the region.

The rainfall of Colorado is small; yet the great altitude causes a considerable local fall of rain and snow, and several important streams take their rise in the state, including several tributaries of the Colorado; the Arkansas, and South-Platte, flowing to the Mississippi; and the Rio Grande, the only stream which reaches the sea under its own name. Extensive and important irrigation-works are fed by some of these streams. Colorado has a great reputation as a health-resort, especially for persons with pulmonary disease. The dryness of the air is the great factor in the recovery of consumptive patients in this region; but some invalids only after a considerable period become so habituated to the rarefaction of the atmosphere as not to be seriously annoyed by it. The medicinal and thermal springs of the state are numerous, and are visited by large numbers. A peculiar disease called 'mountain fever' is endemic in some places, attacking principally strangers from lower levels of country.

Wheat, maize, barley, oats, hay, potatoes, fruits, and garden and dairy products are the staples of agriculture, which is remunerative in all sections where irrigation can be effected. Proposals have been made for a very great extension of irrigation-works at the public expense, and engineering experts have reported that the scheme is entirely feasible. Visitations of insect-plagues, including the well-known Colorado potato-beetle, have hitherto proved very destructive in this state; but the Rocky-mountain locust (see CICADA), formerly a terrible enemy to the farmers, has of late years been comparatively harmless. Cattle and sheep raising are important industries; the stock in 1887 was valued at over \$17,000,000. Lumber-cutting also employs a number of hands.

The discovery of gold (1858) in the neighbourhood of Pike's Peak led to the first important settlements of English-speaking people in this region. The earliest discoveries were of placer-deposits; but quartz-mining soon followed, and although many of the quartz-lodes yield a highly sulphuretted material, the introduction of improved methods of treatment has finally rendered these ores, so refractory under the old processes, highly important as a source of gold. In more recent years a considerable proportion of gold has been afforded by the richly argentiferous lead-carbonate ores, for which the state is famous. Since 1873 the silver production has far exceeded that of gold in importance. The state ranks as the first in the United States in out-turn of silver, second or third in its gold, and first or second in the production of

the precious metals in general. In the working of the best silver ores much lead is obtained, and Colorado takes rank as the first state in lead-production. Vast sums of money have been invested in the construction of works for hoisting and reducing the ores; and railways have been built along the mountain-cañons, generally at a very high cost, so as to make the mines accessible. Mining and smelting operations have been much facilitated by the discovery of large beds of coal, usually of good quality, though classed as a lignite. The most moderate estimates place the total out-turn of gold from its discovery to the end of 1886 at about \$55,000,000, and that of silver at more than \$41,000,000. Iron and Bessemer steel rails are among the manufactures of the state; copper, cement, fireclay, and manganese are wrought to a greater or less extent; and there are thirty petroleum wells near Florence.

History.—Not quite one-half of this region was acquired by the United States from France in the Louisiana purchase of 1804; the remainder was ceded by Mexico under the treaty of 1848, together with California and New Mexico, of which last it formed a portion. The southern part of Colorado has for many years had a small Spanish-speaking population, partially of Indian descent. Colorado was organised as a territory in 1861, and was admitted as a state in 1876. The population is of mixed origin, but is largely derived from the older states of the Union. The distinctly American traits of enterprise and progress, shown alike in business methods and in measures for the spread of popular education, are nowhere more conspicuous than here. The principal towns are Denver, the capital, Leadville, in the carbonate-mining district of the Rocky Mountains (10,200 feet above sea-level), and Pueblo; and there are a number of minor towns of considerable importance, most of them mining centres. Pop. of Colorado (1860) 34,277; (1870) 39,864; (1880) 194,327; (1885) 243,910.

Colorado Beetle (*Chrysomela* or *Doryphora decemlineata*), a North American beetle which commits fearful ravages among potatoes. First discovered near the upper Missouri in 1824 by Thomas Say, it belongs to the sub-order of Coleoptera known as Tetramera or Cryptopentamera, and is a good type of the family Chrysomelidae. It is an oval insect, from 9 to 11 millimetres in length, of an orange colour, with black spots and lines as seen in the figure. The antennae are club-shaped. The larvæ and adults live on the potato-plant, and have sometimes (as in 1859) quite destroyed the crop in certain parts of America. They pass the winter underground, and emerge from their hiding-places in the beginning of May. The

Colorado Beetle:
a, beetle, natural size; b, caterpillar; c, eggs.
(From Miss Ormerod's *Injurious Insects*.)

female lays many hundreds of eggs in groups of twelve to twenty on the under side of potato leaves. The larvæ, which emerge in about a week, are reddish and afterwards orange. They grow up quickly and produce a second generation, which may again produce a third in the same summer. Their rate of multiplication is therefore very rapid.

The home of the Colorado beetle is in the western states; 'from Nebraska and Iowa it

travelled eastward, until, in 1873-76, it reached the eastern shores of America. In 1877 it was found at Liverpool in a cattle-boat from Texas.' Owing in great measure to the stringent regulations of an order in council, which provides that 'it shall not be lawful for any person to sell, keep, or distribute living specimens of the Colorado beetle in any stage,' this pest has fortunately not succeeded in establishing itself in Britain. The surest remedy in case of attack is said to be a preparation of arsenic known as 'Paris Green' or 'Scheele's Green.'

The genus *Chrysomela* ('golden beetle') to which the Colorado beetle belongs, is represented by many hundred often beautifully metallic species in temperate and tropical countries. *C. cerialis*, sometimes injurious to grasses and cereals, *C. staphylea*, *C. or Lina populi*, found on poplars, are common species.

Colorado Springs, a popular summer-resort of Colorado, situated in the midst of beautiful scenery on the *Fontaine qui Bouille* Creek, 75 miles S. of Denver by rail, and about 10 miles E. of Pike's Peak. Pop. 4226.

Colossæ. Colossæ was a town of Asia Minor, in the southern part of the province of Phrygia, situated on the river Lycus, a tributary of the Meander, 12 miles east of Laodicea. It is mentioned by Xenophon as 'a populous city, prosperous and great,' but in the time of Strabo had become 'a small town.' It was ruined by an earthquake in 61 A.D. (Tac. Ann. xiv. 27); but it was again rebuilt, and in the middle ages was named Chonæ. See COLOSSIANS.

Colosse'um. See AMPHITHEATRE.

Colossians, THE EPISTLE TO THE, an epistle sent from Rome by the Apostle Paul about the year 63, in charge of Tychicus, to the church founded at Colossæ apparently by Epaphras. Here Archippus exercised his 'ministry' (iv. 17), and Philemon, together with Apphia 'the sister,' was the entertainer of the brethren. To Philemon Paul persuaded the runaway slave Onesimus, whom he had converted to Christianity, to return. The Colossian church consisted chiefly of Gentile Christians, but was distracted by certain Judaizing teachers, who laid stress on circumcision and ordinances respecting food and festivals (ii. 11 and 16), teaching a thorough-going asceticism, with angel-worship, based on theosophic speculations regarding the higher world of spirits, and may be regarded as the forerunners of the Judaizing Gnostics (q.v.). To counteract these was the chief aim of the epistle (see BIBLE). Its genuineness has been contested by recent criticism. Hilgenfeld, following Baur, holds that 'the Colossian letter has to do with an already fully developed Gnosticism, and this carries it not merely beyond Paul's lifetime, but beyond the first century.' See the commentaries by Ellicott (3d ed. 1865), Bleek (edited by Nitzsch, 1865), and Klöpper (1882); also Holtzmann, *Kritik der Epheser und Kolosserbriefe* (1872); and especially Lightfoot, *St Paul's Epistles to the Colossians and Philemon* (8th ed. 1886).

Colossus, a Greek word of unknown origin, used to denote a statue of gigantic size. The colossal was a common feature of all ancient art, and in particular of Egyptian and Assyrian architecture and sculpture. The image set up by Nebuchadnezzar (Daniel, iii. 1) was of enormous proportions. Even Greek art, through Aristotle, laid down the principle that only the large can be noble, and carried it out in its statues of gods and heroes. Of the many colossi of which accounts have come down to us, the most famous was the bronze colossus of Rhodes, representing Helios (the Sun), the national deity of the Rhodians, which

was reckoned among the seven wonders of the world, though it was by no means a masterpiece of Greek sculpture. It is said to have been the work of Chares of Lindus, a distinguished pupil of Lysippus, who gave twelve years to the casting, and completed his work in 280 B.C. Its height is variously given at from 90 to 120 feet. It stood near the harbour; but the legend that placed it astride the entrance is certainly apocryphal, and probably arose from a misunderstanding of the statement that it was so high that a ship might sail between its legs. Fifty-six years after its erection it was thrown down by an earthquake, and there its ruins lay, the marvel of the place, till in 653 A.D. an Arab general sold them to a Jew from Edessa for old metal. Other famous colossi of antiquity were the Chryselephantine (q.v.) statues of Athena on the Acropolis, 37 feet, and of Zeus at Olympia, 40 feet, both by Phidias; the Zeus at Tarentum, by Lysippus, 107 feet; a bronze Apollo, 66 feet, brought from Apollonia to Rome by Lucullus; and a marble statue of Nero, 131 feet, set up by the emperor before the palace, but removed by Vespasian to the Via Sacra, where Commodus afterwards superseded the head by one of himself. Colossi came in again with the Renaissance, and in later times the most noteworthy have been the S. Charles Borromeo (1697), on the bank of the Lago Maggiore, 72 feet; the 'Bavaria' national statue at Munich, 67 feet; the Arminius (q.v.) statue, 90 feet to the point of the upraised sword; the Virgin of Puy, 51 feet; the figure of Germania in the national monument on the Niederwald, 112 feet; and Bartholdi's 'Liberty enlightening the World' (1886), in New York harbour, 156 feet to the tip of the torch. There are enormous images in Japan, Polynesia, and elsewhere. See Lesbazeilles, *Les Colosses Anciens et Modernes* (1876); Torr, *Rhodes in Ancient and Modern Times* (2 vols. 1885-87).

Colostrum. See BEESTINGS.

Colour is not a material existence; it is a sensation. The colour of an object varies slightly with the brilliancy of the light emanating from it to the eye; and where the eye is abnormal, as in the 'colour-blind,' the apparent colours of objects may differ widely from their colour as perceived by normal eyes. Light is due to waves—or other periodic disturbances whose recurrence resembles that of waves—in the ether of space; and just as air-waves of a certain definite frequency of recurrence will induce in the ear the sensation of a sound of a particular *pitch*, so will the impact of 'ether-waves' of a certain particular frequency induce in the eye a sensation of light of a particular *colour*. We are experimentally acquainted with ether-waves whose frequencies range between 20,000,000,000,000 and 40,000,000,000,000 per second; but the eye is blind to all except a comparatively narrow range of these—viz. from 392 billion to 757 billion per second. Within that comparatively small range, however, we have a large choice of fractional and integral numbers; and each number, each *frequency*, has its own colour. When we look at the spectrum or rainbow we have marshalled before us a series of colours, of which the extreme visible red is produced by about 392 billion, the extreme visible violet by about 757 billion vibrations per second. Between these the eye may rest upon certain distinctive colours, such as yellow, blue, and so on; and the frequencies corresponding to these respective colours are, taking the centre of each distinctive colour as displayed in the spectrum—red, 492.4; orange-red, 484.1; orange, 503.3; orange-yellow, 511.2; yellow, 517.5; green, 570; blue-green, 591.4; cyan-blue, 606; blue, 635.2; violet-

blue, 685.8; puce-violet, 740.5—all in billions (1,000,000,000,000)—per second. Light due to wave-motion of one simple frequency would be 'homogeneous' or 'monochromatic' light; it would produce the simplest colour-sensation; but no such thing is experimentally attainable. The light from burning sodium is a compound of two yellow lights, very near one another in the spectrum, and corresponding to the respective wave-frequencies of 508.9 and 510.6 billions per second; and this is the nearest attainable approximation to monochromatic light.

The eye takes up, singularly enough, any congeries of several monochromatic lights impinging simultaneously upon the same spot in the retina, and the resulting sensation is always that of a single colour, not necessarily resembling any of the components. The retina is composed of numerous ultimate nerve-elements, each of which is capable of perceiving one of three physiologically primary colours. These colours are red, green, and violet (Young and Helmholtz); vermilion, emerald green, and ultramarine blue (Clerk Maxwell); or red, green, and blue (Fick). Simultaneous affection of the elements sensitive to red and of those sensitive to green produces, according to the ratio between the respective irritations, any colour of the spectrum from red through orange and yellow up to green; similarly, green and violet lights blended in different proportions produce all the intermediate blues; and when the whole three sets of nerve-elements are irritated, the sensation is still that of a simple colour, or, it may be by due adjustment, of white light. Coloured lights may be mixed so as to show this, either by causing coloured lights from different sources to coincide in the eye or on a screen, or else, as in the colour-top, by causing ocular impressions of different colours to succeed one another in the eye with such rapidity that the eye or the brain blends them. But nearly every example of what we call coloured light is in reality an admixture of several monochromatic lights—e.g. the light passing through a piece of green glass is composed—as will be found on trying to make a spectrum of it by means of a prism—not only of green light, but also of blue and yellow, and, often enough, of red and violet; but the resultant sensation is that of green, a simple colour.

White light is in general due to a simultaneous impact of wave-motions of all visible frequencies. But the sensation of whiteness may also be produced by the simultaneous impact on the retina of two suitable spectral colours, such as yellow and ultramarine blue; and such a pair of colours are said to be *complementary* to one another; other examples are red and greenish-blue, greenish-yellow and violet, orange and cyan-blue (a rather greenish blue). It will be observed that it is said that yellow and ultramarine blue lights make white light, while it is well known that yellow and blue pigments make a *green* pigment. The explanation of this is that the light from the yellow pigment is not pure; it contains green light; similarly that from the blue pigment contains green light; when the pigments are mixed, the eye receives a simultaneous impression of blue, yellow, and green; but the blue and the yellow destroy one another, being, to the eye, complementary colours; jointly they produce white light; and thus the green alone remains, diluted with white. Complementary coloured lights may both or either be of any degree of complexity; if an aggregate impression of blue light and an aggregate impression of yellow be superimposed on the same part of the retina, whatever be the mode of their production, the result may be the same—an impression of white light.

Colours vary in hue, in purity, and in luminosity. The hue determines the name of the colour—e.g. vermilion, scarlet; the purity or absence of admixture with white light determines its richness—vermilion reflects 80 per cent. of red light mixed with 20 of white; the luminosity or brightness determines the shade or tone of colour. Interfere with any of these and the impression produced upon the eye is modified. Take for example a definite red light, saturated or unadulterated with white light, such a red as may be found in the spectrum; progressively lower its purity by mixing it with white light—it becomes brighter, but passes through light red and pink to pinkish-white tints; lower its luminosity by mixing with black—it passes through terra-cotta tones to brown, which is a dull red; interfere with both purity and luminosity by mixing with various greys—it goes through russets and maroons, the so-called tertiary colours. Any colour in nature can be matched either by a spectral colour or by a purple, treated in this way; and for each such modification of the original colour there will be a different complementary.

The colour of transparent objects is due to Selective Absorption. Look at a red object through a suitable piece of greenish-blue glass, and it appears black; the greenish-blue glass is opaque to the light proceeding from the red object. Hold the same piece of glass up to the sky, and the red lights, which are components of the white light of day, are cut off; what passes through produces a sensation of greenish-blue. The red, which is cut off by absorption, and the greenish-blue, which passes through, are complementary to one another—both being really complex, not monochromatic. The colour of a transparent body will also apparently depend upon the thickness of the layer examined: a thin layer of iodine-vapour absorbs all the constituents of visible white light except blue and red; it therefore appears in daylight to be purple; a thicker layer effects the complete absorption of the red but not that of the blue, and a thicker layer of iodine-vapour therefore appears blue. If looked at in red light, a thin layer of iodine-vapour appears red, while a thick layer will present the blackness of opacity.

Before a non-luminous object can be seen otherwise than by transmitted light it must reflect light; if it reflect none it will appear black; a dustless pool in a mountain-hollow, a liquid in a deep black vessel, may reflect no light to the eye of the observer, and will appear black. (Black is the negation of colour, because it implies that there is no sensation of light; gray, produced by mixing white and black, is white deficient in luminosity). Let the pool become turbid, and there will be some light reflected towards the observer. A coloured liquid in a deep black vessel will have its colour revealed by sprinkling a white powder into it. White light (daylight) enters the liquid; it is reflected in all directions by the white powder; but it is in part absorbed by the liquid, which accordingly appears coloured. Of precisely the same kind is the reflection of light by a solid object. Bodies allow light to traverse them to a very small depth, and then the light is, by internal reflection, turned back in all directions; absorption, meanwhile, comes into play, and the result is that the object appears to have a definite colour, the purity of which is marred by surface-reflection. The white light reflected from the surface of a metal masks its true colour, which is brought out by repeated reflection. Gold is deep orange; copper, scarlet; silver, yellowish-bronze; brass, a rich golden red.

If the light supplied to an object do not contain those kinds of light which it can reflect, the object will appear black or colourless; a bunch of flowers

looked at by the yellow light of burning sodium or of a spirit-lamp with common salt in the wick, will all appear black or colourless except those which are yellow. Surface-reflection modifies the result.

There is one class of cases in which colour is not due to absorption. A haze is blue if its particles be fine enough: if it be composed of coarse particles it at once reflects white light in all directions; but fine particles cause repeated reflection, and at each reflection the reflected light becomes bluer; because those rays which would have been most refracted (the blue and violet) are in fact most largely reflected. The colour of the sky is that of a haze, reflecting light downwards; if there were no dust-haze or water-haze above us, the sky would be black. The light which is not reflected from such a haze is either transmitted through it, yellower or redder in colour, or else it is entirely absorbed. The sun thus appears yellower than it would do if our atmosphere did not intervene. See also DICHROISM, INTERFERENCE, IRIDESCENCE, LIGHT, OPTICS, PHOSPHORESCENCE, PLEIOCHROISM, RAINBOW, SPECTRUM, DYEING, and the articles on the several colours; and for further information, consult *Colour* by A. H. Church (Lond. 1887), and *Colour* by C. T. Whitmell (Cardiff. 1888). For Heraldic Colours, see HERALDRY; for the Ecclesiastical Colours, VESTMENTS; and for Colour in Animals, PIGMENT.

Colour-blindness, a term introduced by Sir David Brewster to denominate a defect of vision owing to which some persons are unable to distinguish certain colours correctly. It is also called *Achromatopsia* (Gr.) and *Daltonism*, from Dalton the chemist, who suffered from the defect, and who gave the first detailed description of it (1794). Of this defect there are several degrees, classified as follows (by Holmgren of Upsala): (1) *Total colour-blindness*, where there is no perception of colours as such, but only of gradations of light and shade; (2) *Complete partial colour-blindness*, where some bright colours, different in different cases, are confused with each other, though other colours are correctly perceived; (3) *Incomplete partial colour-blindness*, where bright colours are recognised, but more delicate shades are confused. The first form is rare, and generally, perhaps always, associated with other defects in the eyes; the third is probably common, though not of great importance; to the second attention will mainly be directed here.

With regard to the classification of the cases of complete partial colour-blindness authorities are not agreed; the important practical point is that in the vast majority red and green are the colours confused. Some confuse a bright red with a green that appears to a normal eye a much lighter colour; some with a green that appears darker. But if suitable tests be applied it will be found that they do not distinguish red and green *as such*. Experience, however, and observation of the different apparent brightness of ordinary reds and greens, enables them to distinguish between them in most cases with wonderful accuracy, so that they may remain unconscious of their defect till some striking mistake, or the application of a systematic test, reveals it. Cases of colour-blindness for yellow and blue, if they occur at all, are extremely rare. Experience proves that this defect is generally hereditary, and is quite incurable. The eyes may be, and usually are, perfect in every other respect; no difference has been detected in their structure, either during life or after death; so the cause of their defective perception remains absolutely unknown.

Numerous careful and extensive researches both in various countries of Europe and in the United States have shown that this defect is present

in about 4 per cent. of the males (or one in twenty-five), and less than 0.5 per cent. of the females in those countries. Now red and green are the very colours which are most largely used for the purpose of signalling both at sea and on railways; and it must be obvious that most disastrous results may follow if the person whose duty it is to distinguish them from each other is unable to do so. It is then an important practical question how the defect may best be recognised. Authorities on the subject are agreed that any test which requires the naming of colours is unsatisfactory, and that for two reasons. First, a person may perceive colours correctly, but may make mistakes through imperfect knowledge of their names; second, a person may be colour-blind, and yet by his perceptions of different brightness in the tests, may name the colours correctly. The most perfect test yet devised is known by the name of its introducer, Holmgren of Upsala, and consists in a number of skeins of wool of different shades. One of these is placed before the person to be tested, generally in the first instance a pale green, and he is asked to select from the remainder those which most resemble it. If colour-blind, he is sure to pick out some of the 'confusion colours,' pale-grays, buffs, &c., to match the green; and further similar tests may then be applied to determine more precisely his defect. Within recent years the importance of this defect has been recognised by the railway companies and the Board of Trade in Britain; though the tests applied are not in either case so satisfactory as is to be desired, as they consist in requiring the candidate to name coloured cards, lights, &c. Moreover, the Board of Trade examination is required only of men applying for certificates as mates or masters of vessels; there is no compulsory examination of ordinary seamen, though one of their most important duties is to keep a lookout at night for signal-lights, many of which are red and green. This arrangement is also productive of much hardship to those unaware of their defect, who have spent valuable years in the drudgery of preparation for a calling to which colour-blindness should be an absolute disqualification, and only find out their unfitness when they should begin to reap the reward of their labour. Further, in certain cases colour-blindness does not prevent the granting of a certificate by the Board of Trade; the fact that its holder is colour-blind is indorsed upon it, but he is permitted to act as master or mate notwithstanding, if he can find a shipowner to employ him.

There are difficulties in the way of substituting any other colours than red and green for signals. Blue and yellow are the only others sufficiently definite and contrasted for the purpose. But blue is much more quickly lost in passing through the air than other colours; and yellow is just the colour to which haze or distance reduces white.

Colour-blindness more or less complete may also occur as the result of disease of the eyes, particularly atrophy of the optic nerve and excessive use of tobacco. See EYE (DISEASES OF), and AMAUROSIS. In the former, the distance from the direct line of sight at which colours can be recognised is diminished; in the latter, the colour of a small disc is not recognised when it is in the direct line of sight, though it may still be perceived at a little distance from it. As in the latter case, the perception of red and green is specially affected, its presence in engine-drivers, &c. may cause even greater risk than the congenital form of colour-blindness. For further information, see article 'Colour-blindness' in *Dictionary of Practical Surgery* (1886); *Colour-blindness, its Dangers and Detection*, by Joy Jeffries (Boston, U.S.); Dr A. Koenig in the *Brit. Assoc. Report* (1886); and the

writings of Sir David Brewster, George Wilson, Clerk Maxwell, &c.

Colour-printing. See LITHOGRAPHY, PRINTING.

Colours, MILITARY, are the flags carried by certain regiments of the British army. Those of the infantry were originally called ensigns, a name still used in the navy. In former times there was one for each company, but now there is, in each Battalion (q.v.), a 'pair of colours,' one (the 'Union Jack,' on a blue ground) called the royal or queen's colour, is the more important, and of the same pattern for all regiments; the other, or regimental colour, matches the facings of the regiment, and has in one corner the blue union, in the centre a wreath of roses, shamrocks, and thistles, with the name, crest, and motto of the regiment, and the campaigns in which it has taken part. The facings of all regiments having the title 'Royal' are blue, otherwise they are white for English, yellow for Scottish, and green for Irish. The East Kent Regiment, formerly famous as the 'Buffs,' retains the buff facings, and is the only exception. English regiments have the St George's cross in red on their white colours. All colours are made of silk, 3 feet 9 inches by 3 feet, fringed with gold, and have crimson and gold cords and tassels, on a staff 8 feet 7 inches long. They are carried on parade by the two junior sub-lieutenants (formerly ensigns), and guarded by two sergeants and two men, forming what is called the 'colour party,' but are no longer taken into battle. Since the Franco-German war of 1870-71 it has been recognised that they make too conspicuous a mark. The last time British colours were taken into the field was in the Zulu war of 1880. An officer trying to save them after Isandula, was drowned in the Tugela, and the colours were found wrapped round his body. Regiments of guard cavalry have oblong 'standards,' 30 inches by 27, and dragoon regiments have 'guidons,' 41 inches by 27, slit in the fly, with the upper and lower corners rounded off at one foot from the end. These flags are all of crimson silk, with gold fringe, cord, and tassels, and bear the crest and campaigns of the regiment. The Royal Artillery, Royal Engineers, Lancers, Hussars, and Rifle regiments have no colours. When a regiment obtains new colours, they are usually solemnly presented by a royal personage or some lady of distinction, with much military pomp, after a special religious service. The old colours are hung up in the cathedral or parish church at the territorial headquarters. A member of the Herald's College is 'inspector of regimental colours.' *Camp colours* are small flags matching the facings of the regiment, to designate the part of the camp it occupies.

Colour-sergeant (so called as being a sergeant who, in addition to other duties, guarded the colours) is the chief non-commissioned officer in a Company (q.v.) of British infantry. On his efficiency its good order mainly depends, as he is the channel of communication between the Captain (q.v.) and the men in almost everything. The distinctive badge consists of crossed colours worn on the sleeve above the Chevrons (q.v.). The pay is 3s. a day in the line, and 3s. 2d. in the guards. The corresponding rank in the cavalry is troop sergeant-major (corporal of horse in the Life and Horse Guards). In the United States army each battalion has a colour-guard, composed of a colour-sergeant and seven corporals. The colour-sergeant carries the national colours.

Colquhoun, JOHN, second son of Sir James Colquhoun of Luss, was born in Edinburgh, 6th March 1805, studied at Edinburgh University,

served in the army 1829-34, and became a supreme authority on sport in Scotland. The famous record of his experiences, *The Moor and Loch*, published in 1840, was much extended and improved in the 4th (1878) and 5th (1884) editions. *Rocks and Rivers* appeared in 1849; *Salmon Cuts and Stray Shots*, 1858; and *Sporting Days*, 1866. He died at Edinburgh, 27th May 1885.

Colquhoun, PATRICK, born at Dumbarton, 14th March 1745, became provost of Glasgow in 1782, went to London in 1789, and in 1792 became a police-magistrate there. He was indefatigable in forwarding administrative legislation, educational and commercial reforms, wrote innumerable pamphlets, and published two important works—*Police of the Metropolis* (1795); and *Population, Wealth, Power, and Resources of the British Empire* (1814). He died 25th April 1820.

Colston, EDWARD. See BRISTOL.

Colt, SAMUEL, inventor, born in Hartford, Connecticut, in 1814, ran away to sea in 1827, and about 1832 travelled over a large part of America, delivering lectures on chemistry by which he obtained the funds required to prosecute his invention. In 1835 he took out his first patent for a revolving pistol, which after the Mexican war was adopted as a regular weapon for the United States army, and since then has been adopted universally. Colt expended over \$2,500,000 on an immense armoury in Hartford, where he died 10th January 1862, and where his widow erected a handsome Episcopal church to his memory. See REVOLVER.

Colt's-foot. See TUSSILAGO.

Coluber, a genus of non-venomous snakes, of almost world-wide distribution. It forms a type of the family Colubridæ, in which the common Ringed English Snake (*Tropidonotus natrix*) is also included. The Æsculapian Snake (*Coluber asculapii*), so familiar from ancient times as a symbol of medicine, is the best known species. It is very common in Italy, is the species of the Schlangenhaut, and is widely distributed in Europe. It is of a predominantly brown colour, attains a length of 4 or 5 feet, and is readily tamed. All the members of the family are very typical, exhibiting few deviations from the general snake structure. See SNAKE.

Columba, ST—called also ST COLUM-CILLE ('Columba of the Churches,') and ST COLM—was born (it is believed at Garton, County Donegal) in the north of Ireland, on 7th December 521. He was of high descent, his father Fedhlimidh, of the powerful tribe of the Cinel Conaill, being a kinsman of several of the princes then reigning in Ireland and in the west of Scotland; and his mother, Eithne, was also of royal blood. After studying under St Finnian at Moville on Strangford Lough, and under another St Finnian at Clonard (where he had as companions St Congall, St Ciaran, and St Cainnech), he spent some time near Dublin; but in 546, when no more than twenty-five, he returned to the north and founded Derry, and, six or seven years afterwards, Durrow, the greatest of all his Irish monasteries. The belief that he had caused the bloody battle of Culdremhine in 561 led to his excommunication by an Irish ecclesiastical synod, and practically to exile from his native land.

Setting out in 563, when in his forty-second year, and accompanied by twelve disciples, he found a resting-place in the little island of Hy or Iona, now better known as Iona (q.v.), or I Colum-cille, and having planted a monastery there, he set himself to the great work of his life, the conversion of the Pictish tribes beyond the Grampians. His missionary efforts were highly successful, but unfortu-

nately very little is known of the way in which he effected his purpose. Bede speaks simply of his 'preaching and example.' Adamnan, extolling his gift of miracles, tells how the gates of the Pictish king's fort near Inverness burst open at his approach, and how, as he chanted the 45th Psalm, his voice was preternaturally strengthened so as to be heard like a thunder-peal above the din and clamour by which the Pictish magicians tried to silence his evening prayer under the walls of the Pictish palace. We get another glimpse of his missionary footsteps from the *Book of Deer* (q.v.), which records how 'Colum-cille and Drostan, the son of Cosreg, his disciple, came from Hy, as God had shown them, to Aberdour,' in Buchan; how 'Bede, a Pict, was then high-steward of Buchan, and gave them that town in freedom for evermore;' how 'they came after that to another town, and it was pleasing to Colum-cille, for that it was full of God's grace; and he asked of the high-steward Bede that he would give it to him, but he gave it not; and, behold, a son of his took an illness, and he was all but dead, and the high-steward went to entreat the clerics that they would make prayer for his son that health might come to him; and he gave in offering to them from Cloch-in-Tiprat to Cloch-Pette-mic-Garnait; and they made the prayer, and health came to him.' In some such way as this St Columba and his disciples seem to have traversed the Pictish mainland, the Western Islands, and the Orkneys, establishing humble monasteries whose inmates ministered to the religious wants of the people. The parent house of Iona exercised supremacy not only over all those monasteries, but over all the monasteries that St Columba had built in Ireland, and over those that were founded by his disciples in the northern provinces of England. Thirty-four years appear to have been spent by St Columba in raising up and perfecting his ecclesiastical system in Scotland. But the labour did not so wholly engross him but that he found time for repeated voyages to Ireland, and for a visit to Glasgow, where St Kentigern or Mungo was restoring Christianity among the Welsh or British tribes of Cumbria and Strathclyde. The health of St Columba seems to have begun to fail in 593, but his life was prolonged till he reached his 76th year, when he breathed his last as he knelt before the altar of his church in Iona a little after midnight, between the 8th and 9th June 597. He was buried within the precinct of his monastery, and his bones—which were afterwards enshrined—the stone pillow on which he slept, his books, his pastoral staff, and other things which he had loved or used, were long held in great veneration.

Whether any original composition of St Columba's still survives is doubtful, though an *Altus* published by Dr Todd in the *Liber Hymnorum*, and republished by the Marquis of Bute in 1882, has been ascribed to him by unbroken tradition. Be this as it may, he was certainly eminent as a transcriber. Adamnan tells us that on the night before his death he was engaged on a transcript of the Psalter, and in the *Annals of Clonmacnois* it is stated that 'he (Columba) wrote three hundred books with his own hand . . . which books have a strange property, which is that if they or any of them had sunk to the bottom of the deepest waters they would not lose one letter, or sign, or character of them, which I have seen tried, partly by myself on that book of them which is at Dorowe.' The two existing specimens of St Columba's work, both preserved at Dublin, are the Book of Durrow just mentioned, and the Psalter known as the Cathac or Battler. This name it has received from the custom of bearing the relics of the ancient Celtic saints into battle as sacred

victory-bringing ensigns. St Columba's crozier was also used in this way.

St Columba's character was very complex, but marked in all things by enthusiasm and earnestness. Warlike and aggressive by temper and descent, as well as from the spirit of the times, he was naturally more inclined to action than to melancholy, and yet he had a tendency to expatiate amid visions; and though his disposition was prevailingly austere, he had frequent gleams of tenderness and kindness. 'Angelic in appearance,' says Adamnan, 'graceful in speech, holy in work, with talents of the highest order and consummate prudence, he lived during thirty-four years an island soldier. He never could spend the space even of one hour without study, or prayer, or writing, or some other holy occupation. So incessantly was he engaged night and day in the unwearied exercises of fasting and watching, that the burden of each of these austerities would seem beyond the power of all human endurance. And still in all these he was beloved by all; for a holy joy ever beaming on his face revealed the joy and gladness with which the Holy Spirit filled his inmost soul.'

In the ecclesiastical system of St Columba as in that of Ireland, the church was essentially monastic with 'neither a territorial episcopacy nor anything like presbyterian parity, but the same anomalous position of the episcopal order. The bishops were under the monastic rule, and as such were in respect of jurisdiction subject to the abbot, even though a presbyter, as the head of the monastery;' but while the power usually reserved to the episcopate was thus transferred to the abbatial office, 'the episcopal orders were fully recognised as constituting a grade superior to that of the presbyters,' and as carrying with them the functions of ordination and celebration of the eucharist according to the episcopal rite. St Columba himself, as well as his followers generally till the year 716, kept Easter on a different day, and shaved their heads after another fashion than obtained in other parts of Western Christendom. But with these exceptions, their creed and rites appear to have been substantially the same.

The chief authority for the life of St Columba is the account written by St Adamnan (q.v.), who was abbot of Iona from 679 to 704, and who incorporated in his work an earlier life by Cuimíne (abbot, 657-669). Of this Dr Reeves published an edition in 1857 for the Bannatyne Club, and it has since been re-issued in the 'Scottish Historian' series (1874). See also Smith's *Life of St Columba* (Edin. 1798); Lanigan's *Ecclesiastical History of Ireland* (1822); Father Innes's *History of Scotland* (Spalding Club, 1853); Montalembert's *Monks of the West*, vol. iii.; Forbes's *Kalendars of Scottish Saints* (Edin. 1872); and Skene's *Celtic Scotland*, vol. ii. (Edin. 1877).

Columban, or COLUMBANUS, ST, one of the most learned, eloquent, and devoted of the many missionaries whom Ireland sent forth to the Continent during the Dark Ages, was born in Leinster in the year 543. Having studied under St Comgall, in the great monastery of Bangor, on the coast of Down, he passed over to France, in his fortieth year, accompanied by twelve companions, and founded successively the monasteries of Anegray, Luxeuil, and Fontaine, in the Vosges country. His adherence to the Irish rule for calculating Easter involved him in controversy with the French bishops in 602; and a few years later, the courage with which he rebuked the vices of the Burgundian court, led to his expulsion, largely at the instigation of the notorious Brunhilda, the king's grandmother. After various travels and adventures, and having for a year or two settled at Bregenz,

near the Lake of Constance, he passed into Lombardy, and in 612 founded the famous monastery of Bobbio, in the Apennines, where he died on the 21st November 615. His life, written within a century after his death, by Jonas, one of his successors in the abbacy of Bobbio, has been repeatedly printed. The writings of St Columban, which are wholly in Latin, consist of a rule for the government of his monastery, six poems on the vanity of life, several letters on ecclesiastical affairs, seventeen short sermons, and a commentary on the Psalms (first published at Rome in 1878). The most complete edition of his works is in Patrick Fleming's *Collectanea Sacra* (Augsburg, 1621; Louvain, 1667), followed by the *Bibliotheca Patrum*, and Migne's *Patrologia Cursus* (1844). The town of San Colombano, in the province of Milan, takes its name from the Irish monk, as the town and canton of St Gall (q.v.), in Switzerland, perpetuate the name of the most favoured of his disciples. See the *Vita* by his successor Jonas of Bobbio, Montalembert's *Monks of the West*, and Wright's *Biographia Literaria*.

Columbarium (Lat.), a dovecot or pigeon-house, which probably differed little in form from those in modern use, but was sometimes built on a much larger scale, as we read in Varro of as many as five thousand birds being kept in the same house. The same name was applied to the niches or pigeon-holes in a particular kind of sepulchral chamber in which the urns (*ollæ*) containing the ashes of dead bodies burned were deposited. Each niche usually contained two urns, and the four walls of the sepulchre sometimes contained as many as one hundred niches or more. The names of the persons were inscribed underneath. Tombs of this description were chiefly used by great families for depositing the ashes of their slaves and dependants.

Columbia, the name of nearly thirty places in the United States, of which the most important are: (1) The capital of South Carolina, at the head of navigation on the Congaree River, 130 miles NNW. of Charleston by rail. The town is regularly built, with several handsome streets, and contains a fine granite state-house (\$3,000,000) and other official buildings. It is the seat of a Presbyterian theological seminary, and of the university of South Carolina (1806). Pop. (1880) 10,036.—(2) A borough of Lancaster county, Pennsylvania, on the Susquehanna, which is here crossed by a railway bridge, 80 miles W. of Philadelphia, with several iron-furnaces and rolling-mills, and manufactures of machinery, flour, &c. Pop. (1887) 9872.—(3) The capital of Maury county, Tennessee, on the Duck River, 45 miles SSW. of Nashville by rail, with manufactures of ploughs, furniture, and flour. Pop. (1887) 5200.—(4) The capital of Boone county, Missouri, 24 miles E. of Boonville, with manufactures of flour, tobacco, and woollens. It is the seat of the state university (1840), which is open to both sexes, and has some five hundred students and fifteen professors. Pop. (1887) 4500.

Columbia, or OREGON, after the Yukon the largest river on the west side of America, rises in British Columbia, on the west slope of the Rocky Mountains, near Mounts Brown and Hooker, in about 50° N. lat., has a very irregular course, generally south-west, through Washington, forms the northern boundary of Oregon for about 350 miles, and enters the Pacific by an estuary 35 miles long and from 3 to 7 wide. Its estimated length is 1400 miles. The area drained by this stream and its affluents, of which the largest are Clarke's Fork and the Snake River (with very remarkable cañons), has been computed at

298,000 sq. m. The river is broken by falls and rapids into many separate portions, and the ingress and egress are embarrassed by a surf-beaten bar. Still, it is open to steamboat navigation from its mouth to the Cascades (160 miles), and goods are carried past the obstruction, for 6 miles, by railway; the next reach, of 50 miles, extends to Dalles, where another railway, of 14 miles, has been constructed past the Great Dalles channel; and immediately above this are two sections, of 185 and 250 miles respectively, navigable for small steamboats. The extraordinarily abundant salmon-fisheries of the Columbia have been largely developed. There are a number of canneries, mostly near the mouth of the river, and in the fifteen years ending 1881 the annual export of canned salmon rose from 4000 to 530,000 cases.

Columbia, BRITISH, is a province of the Dominion of Canada, bounded in the N. by the 60th parallel of latitude; on the S. by the United States; on the W. by the Pacific Ocean and part of Alaska; and on the E. by the provisional districts of Alberta and Athabasca (North-west Territories). The area of the province is recorded as 390,344 sq. m., including Vancouver Island (14,000 sq. m.) and Queen Charlotte Islands (5100 sq. m.). The last named consist of a group of about 150 islands, their united length being 156 miles, lying about 200 miles north-west of Vancouver Island. British Columbia was practically under the control of the Hudson Bay Company until 1858, when owing to the discovery of gold, and the consequent immigration of miners, it was made a crown colony. Vancouver Island was made a crown colony in 1849, and leased to the Hudson Bay Company for ten years. The two colonies were united in 1866, and the province joined the Canadian Confederation on 20th July 1871.

The scenery is rugged and picturesque, being diversified with mountain, lake, and river. Between the western slopes of the Rocky Mountains (highest peaks, Mount Brown, 16,000 feet, and Mount Hooker, 15,700 feet) and the sea the whole of the space is occupied to a considerable extent by spurs and outlying groups belonging to that chain. In the immediate vicinity of the coast these form a nearly continuous line of mountains of moderate elevation, known as the Cascade Range. The territory is well watered by rivers which have their origin in the highlands, and find their way into the Pacific Ocean. Of the rivers the most important is the Fraser, 800 miles long, and 600 yards wide at its principal outlet in the Gulf of Georgia, the arm of the sea which separates Vancouver Island from the mainland. Other rivers in British Columbia are the Columbia (which has only its upper portion within the province), the Stickeen, the Skeena, and the Finlay.

Many varieties of climate are found in this province. That of Vancouver Island and the coast of the mainland is very similar to that of the south of England. The interior of the mainland is divided as to climate into three zones—the south, the middle, and the north. The south lies, for the most part, between the 49th and 51st parallels N. lat., and the fall of rain and snow in this district is slight. It contains a good deal of grass or pasture lands, but for arable purposes the land requires irrigation. Between 51° and 53° N. lat. is the middle zone; it includes the high mountains west of the Columbia, contains dense forests, and the rainfall is considerable. The north zone lies between 53° and 60° N. lat.

Population.—In 1881 the population according to the census returns was 49,459, including 25,661 Indians. It was, in 1888, estimated at between

70,000 and 80,000. The principal towns on Vancouver Island are Victoria, the capital (14,000 inhabitants), and Nanaimo (5000); on the mainland there are New Westminster (4000), formerly the capital of British Columbia, and Vancouver (5000), the terminus of the Canadian Pacific Railway. The Indians of British Columbia are as a rule law-abiding and industrious. The coast Indians live largely by hunting and fishing, and are also employed in connection with the lumber industry and the salmon-canneries.

The province is represented in the Dominion Senate by three members, and in the House of Commons by six. The provincial government is administered by a lieutenant-governor, appointed and paid by the Dominion, and a Legislative Assembly of 27 members, elected by the inhabitants. Education is compulsory and free between the ages of seven and twelve.

The province is not likely to become an agricultural country, but there is a considerable area of land available for arable and pastoral farming both on Vancouver Island and on the mainland in the river-valleys. On the west of the island but little arable land is to be found. The principal settlements are upon the east and south coasts, but good land is still to be found on the east coast, and also on the north. The rich valley of the lower Fraser, or New Westminster district, is the largest compact agricultural area on the mainland. There are large tracts of alluvial soil farther up the Fraser and along some of its most important tributaries. Of the total area (say 250,000,000 acres) only about 500,000 acres are as yet occupied. The fruit-growing industry is expected to become important, but it is still in its infancy. The principal industries of the province are connected with the mines, the fisheries, and the forests. The minerals form one of its chief resources. Gold, coal, silver, iron, copper, galena, mercury, platinum, antimony, bismuth, molybdenum, plumbago, mica, and other minerals have been discovered in different parts, copper being very widely distributed. Gold was produced in 1887 to the value of \$693,709, and the value of the output from 1858 to 1887 was \$50,983,226. The quartz-mines have hardly been touched; all the metal hitherto secured has come from the alluvial deposits. Coal and lignite are known to exist in many parts of the mainland. At Nanaimo, on Vancouver Island, there is a large coal-field, and the mines are the most important on the Pacific coast. Over 413,000 tons were raised in 1887, and 334,839 tons were exported, largely to the United States. Nanaimo is connected by rail with Esquimalt, the headquarters of the Pacific squadron, and the site of a large graving-dock. Iron is found in many localities. The fisheries of the province are most extensive, but excepting the salmon-fishery have not yet been developed. The seas, bays, gulfs, rivers, and lakes of the province swarm with food-fishes. There are numerous salmon-canneries in operation. The fur-sealing industry in the Pacific is also a valuable one. But little timber has yet been cut, notwithstanding the immense forests of magnificent trees that abound in British Columbia. The important commercial trees are the Douglas pine, Menzies fir, yellow cypress, and maple, and the shipments so far have been chiefly to Australia, South America, the Cape, and China.

The value of the imports in 1887 was \$3,626,139, of which \$793,434 came from Great Britain, and \$2,059,035 from the United States. The exports were valued at \$3,371,841. To Great Britain the exports were \$810,977, and to the United States, \$2,220,092.

Until the completion of the Canadian Pacific Railway in 1885, British Columbia was isolated

from the rest of the Dominion, and the various parts of the province had little or no communication with each other. Now, however, everything points to a rapid increase in its population and in the consequent development of its resources. It certainly occupies a favourable position in regard to the markets of the west of South America and Australasia; and it is hoped that it may become the entrepôt for a through trade between Canada, China, and Australia. Lines of steamers are already passing between Vancouver and Hong-kong; and in 1888 proposals were under the consideration of the Imperial, Canadian, and Australian governments for the laying of a cable under the Pacific Ocean.

Columbia, DISTRICT OF, in the United States. See DISTRICT OF COLUMBIA.

Columbia College, in New York city, was founded in 1754 as King's College, and reincorporated under its present title in 1784. The first class, of eight, met in the vestry of old Trinity Church, July 17, 1754; in 1760 the college settled in a building near the city-hall, whence it removed to its present position in 1857. It comprises a department of arts, and schools of law and of mines, all well equipped; it is richly endowed, has a number of scholarships, fellowships, and a good library, and ranks well among the colleges of America. In 1888 it was opened to women.

Columbidae. See PIGEON, BIRD.

Columbine (Ital. *colombina*, 'little dove'), the female mask of the Italian improvised plays, variously figuring as the attendant of Pantaloon's daughter, or, occasionally, as the daughter herself. She is the betrothed of Harlequin, and, frequently clad in a parti-coloured dress resembling the latter's costume, she is hence called *Arlecchinetta*. In other cases she appears in the accurate garb of a chambermaid, but retains always her mask. For the dances of the English harlequinade, see PANTOMIME.

Columbine (*Aquilegia*), a genus of plants of the natural order Ranunculaceæ, having five coloured sepals, which soon fall off, and five petals

Common Columbine (*Aquilegia vulgaris*).

each terminating below in a horn-shaped spur or nectary. The name (from Lat. *columba*, 'a dove') is derived from the resemblance of the nodding flower to a cluster of doves, of which the convergent

nectaries suggest the heads and necks, and the divergent sepals the fluttering wings. They are natives of the temperate and colder regions of the northern hemisphere. One, the Common Columbine (*A. vulgaris*), is found in woods in some parts of Britain, and has long been familiar as an inmate of flower-gardens. It is a perennial, generally 2 to 3 feet high, with flowers of considerable beauty. Columbine was formerly much esteemed for medicinal virtues, which are now seldom heard of.—Some of the other species are very ornamental, and are pretty common in flower-borders.

Columbium. See TANTALUM.

Columbus, the capital of the state of Ohio, on the Scioto River, 116 miles NE. of Cincinnati and 138 miles SSW. of Cleveland. Copyright 1889 in U.S. Its site is level, its streets are by J. B. Lippincott broad, and in the centre of the city Company. is a public square of 10 acres, in which stands the state capitol, a fine stone structure 304 feet long by 184 feet wide. Among other noted edifices are the city-hall, containing a public library and city offices; a court-house erected at a cost of \$400,000; United States government and Board of Trade buildings; a large state penitentiary; a hospital for the insane, with a farm of 300 acres, and accommodation for 900 patients, erected at a cost of \$1,520,980; and institutions for the blind, the deaf and dumb, &c. Here also are located the Ohio State University, with its grounds of 320 acres, and the Capital University (Lutheran), both liberally endowed; and in the public schools over 11,000 pupils are registered. Fourteen lines of railway radiate from the Union Depot in this city in all directions, which, added to the natural advantage of its proximity to the great coal and iron fields of the state, tend to a rapid development of its manufacturing industries. The annual product of its manufactories reaches a value of more than \$15,000,000, giving employment to over 13,000 operatives. Columbus was founded in 1812. Pop. (1870) 31,274; (1880) 51,647; (1888) over 90,000.

Columbus is also the name of some twenty other places in the United States, the most important being: (1) Capital of Muscogee county, Georgia, situated on the Chattahoochee River at the junction of several lines of railroad, 100 miles SSW. of Atlanta. It has a large trade in cotton, and extensive manufactures of cotton, woollen, and iron goods. Pop. (1880) 10,123; (1888, including suburbs) about 31,000.—(2) Capital of Bartholomew county, Indiana, 41 miles S. by E. of Indianapolis, with which it is connected by railway. Pop. about 7000.—(3) Capital of Lowndes county, Mississippi, on the Tombigbee River, and on a branch railroad about 150 miles NE. of Jackson. Pop. about 5000.—(4) Capital of Colorado county, Texas, on the Colorado River, about 95 miles SSE. of Austin by rail. Pop. about 2500.

Columbus, CHRISTOPHER (a Latinised form of the Italian *Cristoforo Colombo*; the Spanish form, *Cristóbal Colón*, corresponds to another Latinisation into *Colonus*), Copyright 1889 in U.S. by J. B. Lippincott a great navigator, and the discoverer of the New World, was born at or near Genoa, probably in 1435 or 1436, or, as some writers have stated, in 1446. His father, Dominico Colombo, seems to have been a wool-comber, and it would appear that in early youth his son Christopher worked at the same trade; but he spent some time, probably not much, at the university of Pavia. When fourteen years old he went to sea. The mariners of those days were fighting men, and we find notices of the young Columbus in an expedition against Naples while in the service of the good King René, Count of Provence, who, on one occasion, sent the young

man to Tunis, to cut out a captured galley. It is not a little remarkable that on this occasion his men, like so many of his later crews, refused to obey his orders; and he was obliged, as more than once in later years, to deceive them as to his real course. The accounts of his early voyages are obscure and of doubtful accuracy. About 1470 he was wrecked in a sea-fight off Cape St Vincent, and reached the shores of Portugal on a plank. In Lisbon he married the daughter of one Perestrello, or Pellostrello, an Italian navigator, who had governed Porto Santo, off Madeira, for the Portuguese king. On this island Columbus resided for some time, making charts for the support of his family, and studying the maps and papers left by his father-in-law.

As early as 1474 he had conceived the design of reaching India by sailing westward. In 1477, he tells us, he 'sailed 100 leagues beyond Thule,' probably to or beyond Iceland, where he may have got some vague hint of the old Norse adventures on the American coast. Columbus soon after this began to seek a patron for his intended expedition. He applied to the senate of Genoa; once or more to King John II. of Portugal; later by letters to Henry VII. of England; then to the rich and powerful dukes of Medina Sidonia and Medina Celi, in Spain, of whom the last named at length referred him to Isabella the Catholic, queen of Castile. His application to the queen was submitted to a body of jurors, most of them ecclesiastics, who reported adversely to the project of the Genoese mariner. Finally, through the intervention of Juan Perez de Marchena, a monk who had been the queen's confessor, he was brought in contact with their Catholic majesties, Ferdinand and Isabella. His plans and demands were once more rejected, but afterwards reconsidered; and finally, after seven years of alternate encouragement and repulse, his proposals were accepted by the monarchs, in the camp of Santa Fé, April 17, 1492. On Friday, August 3, 1492, Columbus, now an admiral, set sail from the bar of Saltes, an island near Palos, in command of the small ship *Santa Maria*, with 50 men, and attended by two little caravels, the *Pinta* and the *Niña*, the whole squadron comprising only 120 adventurers. He first made the Canary Islands, whence, on the 6th of September, he set sail westward. On the 13th a variation of the magnetic needle was observed, a circumstance which struck terror into the hearts of his followers. From this and various other causes he found it hard to keep up the courage and patience of his crews. On Friday, October 12, land was descried. There is no doubt that this first landfall, named San Salvador by Columbus, was one of the Bahama Islands; and the more general recent opinion would appear to be that it was what is now called Watling's Island; but this is not by any means certain. He then visited Cuba and Hayti, which he named Hispaniola or Little Spain, and where he planted a small colony of Spaniards. He set sail on his return with his two caravels (for his flagship had been wrecked), and after an exceedingly tempestuous voyage, the *Niña* alone cast anchor in the Tagus. He re-entered the port of Palos, March 15, 1493. On the very same day the *Pinta* also, which had parted company from him more than a month before, entered the same port, having been driven out of her course to Bayonne. The voyagers brought back with them some gold, various plants, birds, and land animals, and six natives of the West Indies. Columbus was received with the highest honours by the court, then at Barcelona, and was hailed as admiral of the sea and a grandee of Spain.

He sailed on his second voyage on the 25th of September, with three carracks and seventeen small

caravels, and on the 3d of November sighted the island of Dominica in the West Indies. His remaining career presents one long series of failures, vexations, and miseries. After a succession of wretched quarrels with his associates, and a long and desperate illness in Hispaniola, he returned to Spain much dejected in 1496. His third voyage, begun in 1498, resulted in the discovery of the South American mainland. In 1499 Columbus and his brother were sent home in irons by a newly-appointed royal governor; but the king and queen repudiated this action, and restored Columbus to favour. His last great voyage (1502-4), along the south side of the Gulf of Mexico, was accomplished in the midst of great hardships and in many distresses of body and mind. Spanish jealousy of the foreigner and of his well-earned honours worked against him on sea no less than at court. Columbus died at Valladolid, in Spain, May 20, 1506. He was buried at Valladolid; but in 1513 his remains were translated to Seville, whence in 1536, with those of his son Diego, they were removed to Santo Domingo, in Hispaniola. In 1796 they were, it is stated, transferred to the cathedral at Havana; but there is some reason to believe that by mistake it was the bones of Diego Colon, and not those of his father, which were removed on the last-named occasion. At present both Havana and Santo Domingo claim his ashes as their treasure.

A man of ardent impulses and strongly poetical imagination, Columbus was hardly the stuff that leaders are made of; consequently he failed to control the turbulent and adventurous spirits among his followers. Although an honestly and earnestly religious and truly conscientious man, he was not seldom guilty of acts which subsequently brought him many compunctions of conscience. Irritable and impetuous, he was, nevertheless, magnanimous and benevolent. His conduct in the capture and sale of slaves, though justified by the jurists and divines of the time, was indignantly condemned by the queen, and can only be explained by the desire of Columbus and the crown to obtain some revenue from his new discoveries, and by the expectation that while detained in slavery the natives might become christianised.

His brother BARTHOLOMEW, who died in Cuba in 1514, was a man of high character and excellent abilities, and assisted Columbus effectively in his labours. — Another brother, GIACOMO (called in Spain DIEGO), who also assisted him in his West Indian government, was a man of gentle and pacific disposition, but was no match for the turbulent adventurers he attempted to control. — Christopher's eldest son, Diego (about 1480-1526), was the heir to his honours, merits, and misfortunes. The great discoverer left also a natural son, Don Fernando (1488-1539), who wrote an important life of his father, preserved only in an Italian translation (Venice, 1571). In 1578 the last legitimate descendant of Columbus in the male line died.

Among the biographies of Columbus the best in English are those of Irving (1831), St John (1850), Crompton (1859), and Helps (1868). See also *The Narrative and Critical History of America*, edited by Winsor, vol. ii.; Harrissee, *Columb* (Paris, 1884); and Varaldo, *L'Origine di Cristoforo Colombo* (1887).

Columella (Lat., 'a little column') is a term used by botanists, zoologists, and anatomists, in a number of totally distinct senses. Thus, for the conchologist it is (1) the central axis of a spiral univalve; for the vertebrate anatomist it is (2) the auditory ossicle of the amphibian ear. Again, the student of mosses employs the term (3) to denote the central axis of the spore-case of mosses, while in phanerogamic botany the term is some-

times also used (4) in the description of the opening of fruits, with axile placentation, to denote what remains in the centre after the carpels have split away.

Columella, L. JUNIUS MODERATUS, the most learned of Roman writers on practical agriculture, was born at Gades, in Spain, and flourished in the earlier part of the first century of the Christian era. For some time he resided in Syria, but lived chiefly at Rome, and died most probably at Tarentum. His great work, *De Re Rustica*, in 12 books—the tenth upon gardening, written in

dactylic hexameters—is addressed to one Publius Silvinus, and treats of arable and pasture lands, culture of vines, olives, &c., care of domestic animals, &c., respective duties of masters and servants, &c. A supplementary treatise relates to trees. This ancient 'Book of the Farm' is written in good Latin, and the information is copious, though not precise, and in some points of questionable accuracy. The best edition is that by Schneider in the *Scriptores Rei Rusticæ* (4 vols. Leip. 1794-97).

Column, a round pillar, usually provided with a base and capital, employed in architecture for the support of an Entablature (q.v.) or other superstructure. Fig. 1 shows in detail the names of the different parts of a column. Columns are doubtless derived from the primitive use of stems of trees in a similar position. Thus the early Egyptian columns are evident imitations of bundles of reeds bound together, or of the stems of palm-trees (figs. 2 and 3). A flat stone laid beneath to prevent the column from sinking, and another on the top to receive the lintel, would naturally suggest the base and capital. In the Classic 'orders' the column played an important part, the proportions of all the different members being regulated by the diameter of the column. In Greek Doric the height of the column varied from 5 to 8 diameters, and the other orders from 8 to 10 diameters. Columns invariably taper from base to cap, with a slight swelling

Fig. 1.—Tuscan Column.

in the centre called the entasis, and they were frequently carved with flutings or channels (see FLUTING). The most conspicuous distinction was the capital. The characteristics of the three Grecian orders, with the plain Doric capital, the Ionic volutes, the Corinthian leafage, will be seen from the accompanying cuts (figs. 4, 5, 6), and will be

in the centre called the entasis, and they were frequently carved with flutings or channels (see FLUTING). The most conspicuous distinction was the capital. The characteristics of the three Grecian orders, with the plain Doric capital, the Ionic volutes, the Corinthian leafage, will be seen from the accompanying cuts (figs. 4, 5, 6), and will be

further dealt with in GREEK ARCHITECTURE; the Tuscan column is also shown in fig. 1. The composite column retained the general proportions of the Ionic, with the Corinthian capital. For a Byzantine capital, see BYZANTINE ARCHITECTURE. In Gothic, columns are also much used, but their variety is infinite, and not regulated by any fixed

Fig. 4.—Doric.

Fig. 5.—Ionic.

Fig. 6.—Corinthian.

proportions like the Classic columns. The articles on the various styles of architecture show many forms of columns. A single column was sometimes erected to commemorate some remarkable event or great personage, such as Trajan's Column in Rome.

Column is a military formation several ranks in depth, and of any length of front, adopted for convenience of movement; line formation being only two ranks deep and suited for actual fighting in consequence of the wide front of fire that can be developed. Previous to the introduction of the breechloading rifle, and the consequent increase in the advantages of a wide front of fire, most European nations fought in column, and especially the French, who, under the first Napoleon, sometimes formed very heavy columns of infantry by ranging many battalions in line, one behind the other. British infantry always fought in line. A thin single rank formation is now universal for the leading troops in battle; but the supports move in column until obliged, by hostile fire, to deploy into line.

A British battalion in column has its companies each two deep, one behind the other, at distances equal to the front of one company, so that on wheeling into line to either flank, no gaps are left. In half-column these distances are halved, and in quarter-column they are reduced to six paces.

Cavalry may be formed in columns of four squadrons, or eight troops; or each squadron may be formed into a column of two troops, the wheeling distance in each case being preserved or reduced as for infantry. Artillery form in columns of batteries, half-batteries, or divisions—i.e. with a front of six, three, or two guns at wheeling distances, which are reduced to four yards in quarter-column.

Column of fours is the formation adopted for marching along a road and for manoeuvres. Infantry are then four abreast, cavalry eight—i.e. each rank is four horses abreast. In column of sections (the cavalry route formation) the rear rank follows behind those of the front rank, instead of marching in line with them. Column of route for artillery and transport is one gun or wagon followed by another at four yards' distance, and so on.

In the United States, besides the column of fours, there is a double column of fours. Other columns

are the column by platoons, by companies, the column by divisions (of two companies each), &c.

Colure. See ARMILLARY SPHERE.

Colvin, SIDNEY, was born at Norwood, Surrey, 18th June 1845. He was educated at Trinity College, Cambridge, where in 1865 he gained the chancellor's medal for English verse, and graduating in 1867 as third classic, became a fellow of his college in 1869. He was elected Slade professor of Fine Art in the university of Cambridge in 1873, and director of the Fitzwilliam Museum in 1876, appointments which he resigned after succeeding G. W. Reid as keeper of the Department of Prints and Drawings in the British Museum in 1884. His numerous contributions to the periodicals, marked by accurate scholarship and poetic feeling, include a valuable series of papers on 'Albert Durer, his Teachers, his Rivals, and his Scholars' (published in the *Portfolio* for 1877); and his separate works are: *Notes on the Exhibitions of the Royal Academy and Old Water-colour Society* (reprinted from the *Globe*, 1869), *A Word for Germany by an English Republican* (1870), *Children in Italian and English Design* (1872), *Drawings by Flaxman* (1876), and *Landor* (1881) and *Keats* (1886) in the 'English Men of Letters' series. He has also edited a volume of *Selections from Landor* (1884).

Colza. See RAPE.

Coma, a Greek word used in medicine, to signify a state of more or less profound insensibility allied to sleep, but differing from natural sleep in its characters as well as in the circumstances under which it occurs. In coma the patient lies on his back, and is either simply insensible to external impressions, or has a confused and dull perception of them, with restlessness and low Delirium (q.v.). The former kind of coma occurs in apoplexy and epilepsy, and also in many other organic diseases of the brain and its membranes, of which, indeed, it may be said to be the natural termination. It is also seen in narcotic poisoning, and most characteristically in poisoning by Opium (q.v.). In the most fatal forms, the breathing is very slow and noisy (snoring or stertorous), accompanied with puffing of the cheeks; the pulse is at first strong and regular, afterwards feeble; there is often lividity; and the pupils are either contracted or excessively dilated, but in either case immovable, and totally insensible to light. In the second variety of coma, there is perpetual restless delirium, without enough of sensibility to lead to spontaneous and regular voluntary movements; the patient mutters slightly, and grasps feebly and without purpose at any object in his way; the pupils are commonly contracted, and the tongue is apt to be dry and brown. This kind of coma is mainly seen in many fevers, and forms one of the modes of their fatal termination. The treatment of coma is that of the disease or accident leading to it. Where there is a reasonable chance of recovery, the patient must be roused to consciousness as much as possible, either by frequent movements or strong impressions on the skin, or by the use of galvanism, so as to maintain the respiration (see OPIUM). Blistering of the head is also sometimes resorted to with good effect.

Comacchio, a walled town of Italy, 30 miles ESE. of Ferrara, on an island in the east of the Valli di Comacchio, a shallow lagoon, about 90 miles in circumference, shut out from the Adriatic by a belt of land, 3 miles wide. It is a bishop's see, and has several fine churches. There are large salt-works and extensive fisheries, the fry of the eel and mullet being admitted to the lagoon in spring by canals opening to the sea, and exit after the fish are grown being prevented by nets and other contrivances, which are referred to both by

Tasso and Ariosto. Over 2,000,000 lb. of fish are caught annually. Pop. 7535.

Comanches, a tribe of American Indians, belonging to the Shoshone family, and ranging for the most part over the prairie-lands of Texas and Mexico. Splendid horsemen, warlike, and fond of plunder, they have until very recently been troublesome neighbours; but they are now among the most tractable and progressive of the Indians called 'blanket Indians.' Honesty, truthfulness, self-respect, and regard for chastity are marked characters of this tribe. They are to some extent addicted to intoxication, which they procure by means of a species of cactus which has narcotic qualities. Their numbers were estimated at 12,000 in 1847; now they are about 4000.

Comat'ula. See CRINOIDEÆ.

Comaya'gua, a city of Honduras, Central America, is situated in a fertile valley, 1935 feet above the sea, on the Rio Humuya, 190 miles E. of Guatemala. Founded in 1540, it has a handsome cathedral and a college, and before 1880 was capital of the state. Pop. about 10,000.

Comb (Saxon *camb*). This well-known toothed implement has been used in every age and by all peoples for dressing and keeping clean the hair. Combs are also used for fastening the hair when dressed, and as head ornaments. In early times the bodkin (*acus*), equivalent to the modern hair-pin, was employed for the latter purpose, but in mediæval times elaborately ornamented combs, sometimes of precious metal, were used for ornamental hair fastening. An allusion to this practice we have in the ancient Scottish ballad of *Sir Patrick Spens*:

O lang, lang may their ladies sit,
Wi' their gowd kames in their hair.

Fig. 1 represents an ancient Irish long rack comb in the museum of the Royal Irish Academy.

Fig. 1.

Fig. 2 is an example of an ancient Scottish double-edged comb of bone from the Broch of

Fig. 2.

Burrian, Orkney, drawn to half the size of the original.

Combs of ivory or of boxwood have been frequently found in early Christian tombs, it being a common practice of antiquity to inclose in the sepulchre objects, especially those of the toilet, that had been used by the deceased. For a late instance, see the article on ST CUTHBERT. Combs also figure commonly in inventories of articles belonging to the mediæval churches, and, being made use of by the priests prior to service, that they might approach the altar with the more decency, these instruments became in some sort sanctified by their employment.

Combs are made of horn, tortoiseshell, ivory, wood, bone, metal, india-rubber, and of a com-

position called xylonite (see CELLULOID). In dealing with horn, which is the principal comb-making material, the horns are cut into rectangular pieces in a manner which involves the least possible loss. These segments are damped and heated till they become soft, when they are opened out and pressed quite flat. The plates are next squared, smoothed, and trimmed preparatory to the tooth-cutting, which formerly was done with a *stadda*, or double saw, having two blades of steel set parallel to each other, with a space between them equal to the thickness of the intended tooth. Tooth-cutting is now done by small circular saws to which the plates are automatically applied, the horn moving the space of a tooth after each cut. In this way 70 or 80 teeth may be cut in an inch of ivory for fine-toothed combs. The teeth are then thinned, smoothed, and finished by means of thin wedge-shaped files. Saw-cutting is the only process available for bone, ivory, and wooden combs, and it is used for the finer kinds of horn combs also.

A great economy of material and time, however, is effected by making horn and tortoiseshell combs by the method of 'twinning' or parting. By saw-cutting, the material corresponding to the spaces between the teeth is of course wasted; by the process of parting, this is made available to form

Fig. 3.

the teeth of a second comb. The annexed figure will show how this may be effected. The prepared horny plate is cut through by means of a stamping-cutter, consisting of two thin chisels inclined to each other, as *ac* and *bd*, which represent their edges; between these, and connecting the ends, *c*, *d*, is a small cross-chisel. When this compound cutter descends with sufficient force upon the plate, it will cut one of the teeth shown in the figure. By simple machinery, the table carrying the plate is made to advance a distance equal to the thickness of one tooth while the cutter is rising, and thus the successive cuts are made as represented. A slight pull is now sufficient to part the plate into two combs, the teeth of which only require filing and finishing.

India-rubber combs, now so extensively used, are manufactured by pressing the caoutchouc to the required form in moulds, and 'vulcanising' or combining it with sulphur afterwards. Xylonite combs are similarly made by moulding; but the comb teeth of these materials do not possess the strength and elasticity which pertain to horny substances and ivory.

Comb, a crest of skin, usually brightly coloured, found on the crown of the head in many birds. It often occurs on both sexes, but usually predominates in the males. In some cases it is supported by a bony protuberance of the skull. Like the analogous wattles, combs probably owe the perfecting of their development to Sexual Selection (q.v.).

Comb, or **COOMB**, an old corn-measure containing four bushels.

Combatants, in the armies of civilised nations, are soldiers whose duty it is to fight both in attack and defence. They are either cavalry, artillery, engineers, or infantry. Non-combatants, on the other hand, perform administrative duties, and fight only in self-defence, though soldiers and

armed, as in the commissariat, transport, ordnance store, medical, pay, and veterinary departments. See **FRANC-TIREURS**.

In the navy, all seamen are combatants, but engineers, doctors, paymasters, and chaplains are non-combatants.

Combe, ANDREW, M.D., physician and physiologist, was born in Edinburgh, October 27, 1797. He studied medicine there and at Paris, and in 1823 commenced to practise in his native city. In 1836 he received the appointment of physician to the king of the Belgians, but his health failing, he returned to Scotland, where in 1838 he became one of the physicians to Queen Victoria. Mild, benevolent, and wise, Andrew Combe obtained the esteem and admiration of all who could appreciate purity and excellence of character. By patient adherence to physiological principles in the treatment of a delicate constitution, he combated a serious pulmonary disease for nearly thirty years at home and abroad. His death was probably hastened by exposure to the poisonous air of an emigrant ship, in which he made a voyage to America: he wrote to the *Times* on the urgent necessity of a law regulating the sanitary arrangements in emigrant vessels, and in 1849 an act provided a remedy for the evil. He died at Gorgie, near Edinburgh, August 9, 1847. His principal works are: *Observations on Mental Derangement* (1831), *Principles of Physiology* (1834; 15th ed. 1860), *The Physiology of Digestion* (1836; 10th ed. 1860), and *The Management of Infancy* (1840; 10th ed. 1870). See his *Life* by his brother, George Combe (1850).

Combe, GEORGE, phrenologist and moral philosopher, the son of a brewer, was born October 21, 1788, in Edinburgh. He became a Writer to the Signet in 1812, and continued to practise until 1837, when he resolved to devote himself to popularising his views on phrenology and education. As early as 1816, he had made the acquaintance of Spurzheim, and become a convert to his system of phrenology. The result was his *Essays on Phrenology* (1819), and his *Elements of Phrenology* (1824), which reached a ninth edition in 1862. But his most important production is *The Constitution of Man* (1828; 9th ed. 1879), in which he endeavours to demonstrate the essential harmony of the nature of man with the surrounding world, and the necessity of studying the laws of nature. Combe's doctrines were violently opposed, being considered by many as inimical to revealed religion. He numbered amongst his friends Cobden, Robert Chambers, and Miss Evans (George Eliot). Combe contributed largely to the *Phrenological Journal* (20 vols. 1824-47) and to *Chambers's Journal* and the *Scotsman*. He travelled and lectured in the United Kingdom, Germany, and America, and published *Notes on the United States* (1841). He died 14th August 1858. Combe married, in 1833, Cecilia (1794-1868), daughter of the celebrated Mrs Siddons. Besides the works mentioned, he wrote *Lectures on Popular Education* (1833), *Moral Philosophy* (1840), *Principles of Criminal Legislation* (1854), *Phrenology applied to Painting and Sculpture* (1855), *The Currency Question* (1855), *The Relation between Science and Religion* (1857). His writings roused popular interest in the science of healthy living, but the phrenological works are obsolete. Combe's ideas on popular education were put into experimental shape in a secular school which he founded in Edinburgh in 1848, where the sciences were taught, including physiology and phrenology; but it was too much in advance of its time, and after a few years had to be abandoned. All his subjects, save phrenology, are now

taught in every well-appointed board school. A physiology lectureship was founded by the trustees of George and Andrew Combe. See the *Life* by C. Gibbon (1878); and Combe's views and articles on *Education*, collected by Jolly (1879).

Combe, WILLIAM, author of *Dr Syntar*, was born at Bristol in 1741, and educated at Eton and Oxford, which he quitted without a degree. 'Godson' (or natural son) of a rich London alderman, who died in 1782, leaving him £2150, he led for some years the life of an adventurer, now keeping a princely style at the fashionable watering-places, anon a cook at Douai, and a common soldier. The last forty-three years of his life were passed mostly within the 'rules' of the King's Bench debtors' prison; but he died at Lambeth, 19th June 1823. In the *Dictionary of National Biography* (vol. xi., 1887) Professor Tout enumerates eighty-six works by Combe, published between 1774 and 1824; of these, the *Three Tours of Dr Syntar* (1812-21) alone are remembered, and even they owe much to Rowlandson's illustrations.

Combermere, VISCOUNT (Stapleton Stapleton-Cotton), a British field-marshal, son of Sir Robert Salisbury Cotton, Bart., of Combermere Abbey, Cheshire, was born in 1773 at Llewenny Hall, Denbighshire. Educated at Westminster School, he entered the army in 1790, and in 1794 was made lieutenant-colonel of a new regiment of light dragoons, with whom he served in India for several years. In 1808 he proceeded, with the rank of major-general, to the Peninsula; in 1809 he succeeded to the baronetcy; and in 1810 he was appointed to the command of the whole allied cavalry. He was present at the battles of Talavera, Llerena, Salamanca, the Pyrenees, Orthez, and Toulouse, and was raised to the peerage in 1814 as Baron Combermere; although not at Waterloo, he had the command of the cavalry of the army of occupation in France. He was commander of the forces in the West Indies, 1817-20; commander-in-chief in Ireland, 1822-25; and commander of the forces in India, 1825-30, where he captured Bhartpur. Raised to the rank of viscount in 1827, he succeeded Wellington as Constable of the Tower in 1852, and was made a field-marshal in 1855. He died February 21, 1865. See his *Correspondence* (2 vols. 1866).

Combination. A combination to commit a crime is, in English law, an indictable Conspiracy (q.v.). A combination to commit an act which is injurious, immoral, or contrary to public policy, is in some but not in all cases held to amount to conspiracy. Combinations of workmen to raise the rate of wages were formerly unlawful; but the law was amended in this respect in 1825, and now such combinations are freely permitted, provided they effect their purposes by lawful means. See CONSPIRACY and TRADE-UNIONS.—For LAWS OF COMBINATIONS, in Chemistry, see ATOMIC THEORY, CHEMISTRY; for COMBINATIONS, in Mathematics, see PERMUTATIONS.

Combining, of wool, cotton, &c. See COTTON, WOOL, SPINNING.

Combretaceæ, a tropical sub-order of Myrtifloræ, including about 240 species of trees and shrubs, mostly astringent.

Combustion is the term commonly applied to those chemical processes which are accompanied in a marked degree by the production of heat and light. The most familiar of such processes are those in which oxygen of the atmosphere combines chemically with the constituents of what are ordinarily spoken of as combustible substances, such as wood, coal, fats, oils, &c. Chemical combination is, as a rule, accompanied by the evolution

of heat and frequently of light (see CHEMISTRY); but every case of chemical combination is not called combustion, because in many cases the quantity of heat evolved is inconsiderable.

When we speak of the combustion of, for instance, coal or wood, we mean the chemical process which consists, in general terms, in the combination of the oxygen of the air with the carbon and hydrogen which constitute the greater part of the combustible portion of either of these substances, and in the production of carbonic acid and water. Many instances are known to chemists in which the oxygen required for a combustion is not derived directly from the atmosphere, but from some oxidising (or oxygen-yielding) agent, and frequently the place of the oxygen may be altogether taken by some other element, as, for instance, when metals, such as antimony in powder, burn in chlorine.

The combustion of every combustible substance is accompanied by the evolution of a quite definite quantity of heat, which is invariable for each substance, whether the combustion takes place rapidly or slowly. A piece of phosphorus, for instance, as is well known, glows in the dark. This is a process of very slow combustion, and is never accompanied by much rise of temperature. When moderately heated in air, a piece of phosphorus bursts into flame, and the combustion is rapid and is accompanied by a considerable rise of temperature; whilst if the phosphorus be burned in pure oxygen, the combustion is an extremely brilliant spectacle, and a high temperature is attained. In each case the actual quantity of heat given out is identical for the same weight of phosphorus, but the time occupied by the combustion varies, and consequently the temperature at any given instant must also vary.

The quantities of heat given out by the combustion of the same weights of different substances vary greatly. The measurement of quantities of heat produced by combustion and in other ways is called calorimetry (see HEAT).

The name combustion is applied to a particular process in the analysis of organic compounds. See ANALYSIS (ORGANIC). See also SPONTANEOUS COMBUSTION.

Comedy. See DRAMA.

Comenius, JOHN AMOS (properly KOMENSKI), a distinguished educational reformer of the 17th century, was born 28th March 1592, in Moravia, either at Comna or at Nivnitz. His parents belonged to the Moravian Brethren. He studied at Herborn (1612), and then at Heidelberg, became rector of the Moravian school of Prerau (1614-16), and minister at Fulnek, but lost all his property and library in 1621, when that town was taken by the Imperialists. He became a wanderer, and settled at Lissa, Poland. Here he worked out his new theory and method of education, wrote his *Didactica Magna*, and was chosen bishop of the Moravian Brethren in 1632. In 1631 he published his *Janua Linguarum Reserata*, which was translated into many European, and even into some oriental languages. There is a trilingual edition, with woodcuts, in the Advocates' Library, Edinburgh. In this work he points out a method of learning languages new at that time, which has been called the intuitive or perceptive system, in which the pupils were taught by a series of lessons on subjects easily understood or appreciable by the senses—such as natural history, the sciences, different trades and professions, &c. The *Vestibulum*, an introduction to the same, appeared in 1633. Comenius also published about the same time the *Ratio Disciplinae Ordinisque*

Ecclesiae in Unitate Fratrum Bohemorum (1632; republished 1702); and his *Pansophiae Prodomus* (1639), an attempt at a complete statement of the circle of knowledge. In 1641 Comenius was invited to England by parliament, through the philanthropist Hartlieb, to assist in reforming the system of public instruction; but as the breaking out of the Civil War prevented the execution of this design, he went to Sweden (1642). There he was patronised by Oxenstiern, who gave him a commission to draw up a plan for the organisation of schools in Sweden; and this he completed at Elbing, four years afterwards. He also put to press (1643) a treatise on Pansophia. He returned to his Polish home at Lissa in 1648, and elaborated his work there. He next went (1650) to Saros-Patak, Hungary, for a similar purpose. Here he composed his celebrated *Orbis Sensuatum Pictus*, or *The Visible World* (Nurem. 1658), the first picture-book for children, which has been often reprinted and imitated. Finally, he settled in Amsterdam, where he published several other works. He died at Naarden on the 15th November 1671. Bacon's speculations appear to have stirred the imagination of Comenius to the conception of universal and systematised learning, to which he gave the name of Pansophia or Encyclopaedia.

His educational and pansophic works were published at Amsterdam (4 vols. 1657), and dedicated to the city of Amsterdam in recognition of his hospitable treatment there. In education he was a realist; he was also fervently evangelical, and his whole system was intended to lead up to knowledge, virtue, and piety. Late in life a mystical tendency was apparent in his works. Whatever may be thought of his educational system, he first fully developed educational method, made important reforms in the teaching of languages, and introduced into schools the study of Nature. See Laurie's *Comenius, his Life and Work* (1881).

Comes. See COUNT, EARL.

Comet. The word comet is derived from the Greek *kómē*, 'hair,' a title which had its origin in the hairy appearance often exhibited by the haze or luminous vapour, the presence of which is at first sight the most striking characteristic of the celestial bodies called by this name. The general features of a comet are—a definite point or nucleus, a nebulous light surrounding the nucleus, and a luminous train preceding or following the nucleus. Anciently, when the train preceded the nucleus—as is the case when a comet has passed its perihelion, and recedes from the sun—it was called the beard, being only termed the tail when seen following the nucleus as the sun is approached. This distinction has disappeared from all modern astronomical works, and the name tail is given to the appendage, whatever its apparent position. Neither the tail nor the nucleus is now considered an essential cometary element, but all bodies visible in interplanetary space, which describe orbits round the sun of an extremely elongated form, are classed as comets. There are several plain points of difference between comets and planets. The planets move all in the same direction, from west to east, which is astronomically called 'direct motion;' but the movements of comets are often from east to west, or retrograde. The orbits of all the planets are confined to a zone of no great breadth on either side of the ecliptic; but the paths of comets cut the ecliptic in every direction, some being even perpendicular to it. The orbits of all the planets are nearly circular; or, more properly speaking, are ellipses of very small eccentricity. The orbits of comets, on the other hand, present every variety of eccentricity, some of them being ellipses or elongated closed

orbits of various degrees of elongation; others, hyperbolas; while the majority have a form of orbit not differing sensibly from the parabola, which is the limiting form of curve to which both the ellipse and hyperbola approximate under given conditions.

Let p be the point of perihelion passage of a comet, and let the direction of its motion be in the direction indicated by the arrow. There is a certain velocity of motion at this point which would give the orbit the form of a parabola, pa^1 , the direction of motion always tending to parallelism with the straight line through pS . Any

velocity less than this would cause it to describe a closed curve, pa^2 , any greater velocity would cause it to describe the hyperbola, pa^3 , in which case it would approximate to the direction of the straight line, CD, and would never return. This would be the case if there were no disturbing force to interfere with the sun's attraction; and conversely, comets approaching the sun along the various paths above described would pass the perihelion with the various velocities above indicated. Any attraction, however, of an extraneous body interfering with the attraction of the sun might change the orbit from the ellipse to the hyperbola, and *vice versa*, or from the parabola to either. As, however, there is only one parabola corresponding to infinite sets of ellipses and hyperbolas, an interfering cause is not likely to change the orbit from an ellipse or hyperbola to the parabolic form.

There are twenty *known* periodical comets, eleven of which have been observed at more than one perihelion passage. These latter have periods in years as follows: Encke's, 3.3; Winnecke's, 5.6; Brorsen's, 5.5; Tempel's I, 6; D'Arrest's, 6.4; Biela's, 6.6; Faye's, 7.4; Tuttle's, 13.8; Halley's, 76; Tempel's II, 5.2; Swift's, 5.5.

The orbits of forty-three comets appear to be ellipses. These are *probably* periodical. The paths of about two hundred cannot be distinguished from parabolas. These are *possibly* periodical, as the ellipse, when very eccentric, cannot near perihelion be distinguished from a parabola. Only six or seven have orbits possibly hyperbolic.

Elliptic comets in a large majority move *directly*—i.e. from west to east. Parabolic comets usually move in the contrary direction. But, on the whole, there is no general tendency in these bodies to move either way. Periodic comets have orbits but little inclined to the ecliptic; but, on the whole, cometary orbits show a tendency to gather round a plane inclined 50° to the ecliptic. The perihelia gather about two opposite regions, in longitude 60° to 120° , and 240° to 300° . The nodes of the orbits gather also about two regions, not, however, directly opposite.

The discovery that comets are celestial bodies, extraneous to our atmosphere, is due to Tycho Brahé, who measured the parallax of the comet

of 1557. Newton succeeded in demonstrating that they are guided in their movements by the same principle which controls the planets in their orbits; and Halley was the first, by determining the parabolic elements of a number of comets from the recorded observations, to identify the comet of 1682 with one which had been observed in 1607 and the observations recorded by Kepler and Longomontanus, and also with a comet observed in 1531 by Apian, at Ingoldstadt, and thus confidently to predict the return at the end of 1758 or beginning of 1759, of a comet which would have the same parabolic elements. These parabolic elements are elements of a parabola nearly coincident with the elongated elliptic orbit of the comet. They are: (1) The inclination. (2) The longitude of the node. These two determine the plane of the orbit. (3) The longitude of the perihelion, or point of nearest approach to the sun. (4) The perihelion distance, or nearness of approach to the sun. (5) The time of perihelion passage. (6) The direction of motion, whether direct or retrograde.

To determine these parabolic elements, three observations of the comet are sufficient; and by a table of such elements deduced from the recorded observations, it is possible at once to ascertain whether any newly observed comet is identical with any that have been previously observed. To predict, however, with accuracy the time of the return of a comet, a much more elaborate calculation must be made of the orbit, taking into account the perturbations of the planets to whose influence it is subject. This difficult problem was solved, in the case of Halley's comet, by the joint work of Laland, Madams, Lepante, and Clairaut, who announced, in November 1758, just as astronomers began to look out for the return of the comet, that it would take 618 days more to return to the perihelion than on the preceding revolution. The perihelion passage was fixed about the middle of April 1759; but Clairaut distinctly forewarned the world that, being pressed for time, he had neglected small values, which collectively might amount to about a month in the seventy-six years. The comet passed the perihelion on the 12th March 1759, exactly a month before the time announced, but within the assigned limits of divergence from that date. The elements of its orbit proclaimed it to be the comet of the former periods by their similarity. For the next perihelion passage, the different calculations executed by MM. Damoiseau, Rosenberger, Lehmann, and De Pontécoulant, fixed respectively the 4th, the 26th, the 11th, and the 13th November 1835. Subsequently, observations indicated the 16th—that is to say, a deviation of only three days from what turned out the most accurate calculation, and a deviation of twelve days from the most remote. We have adverted to the perihelion passages of this comet in 1531, 1607, 1682, 1759, and 1835. It is also now identified with a comet observed in 1456, and one in 1378, recorded by Chinese observations. There are no sufficiently reliable European observations previous to 1456, but it is conjectured by Arago that this comet is the same with the comet of 1305; that of 1230; a comet mentioned in 1006 by Hali Ben Rodan; that of 885; finally, a comet seen in the year 52 before our era.

This account of Halley's comet has been given at length to illustrate the principles on which the calculations are made. A simple method, due to Olbers, enables the elements of cometary orbits to be calculated in a comparatively short time, and almost all comets discovered have now their paths roughly determined soon after they become visible.

There are two other periodical comets of peculiar interest: (1) That of Encke, with a short period of 1204 days. Its orbit does not extend so far as

the orbit of Jupiter, and a slight acceleration in its periodic times of return was regarded until lately as suggesting the possibility of the space, within our solar system at least, being occupied by a resisting medium, though of extreme rarity. (2) That of Biela or Gambart, having a period of six years and three-quarters. During the visit of this comet in 1846, it was seen first at New Haven, U.S., by Messrs Herrick and Bradley, on December 29, 1845, in the act of separating into two distinct comets, which kept moving side by side till they disappeared. On the return of the comet in the autumn of 1852, the distance between the two nuclei had much increased. Since then, although repeatedly due, it has not again been seen.

The celebrated comet of 1680, which furnished Newton with the occasion for proving that comets revolve around the sun in conic sections, and that, consequently, they are retained in their orbits by the same force as that which regulates the movements of the planets, appears to have been about the most remarkable for brilliancy of any of which we have authentic accounts. This comet is supposed to be identical with the one that appeared about the time

of Caesar's death (44 B.C.), with that which was seen in the reign of Justinian in the year 531, and with another in the year 1106, in the reign of Henry H., the period of revolution, according to the orbit calculated for it by Whiston, being about 575 years. There is, however, some doubt among astronomers as to the real form of its orbit, the one assigned to it by Encke giving it a period of 8813 years. This comet approached nearer to the sun than any known, except that of 1843. The comet of 1680

approached the sun within the 163d of the semi-diameter of the earth's orbit. The annexed diagram shows a part of its path; the same diagram shows the direction of the tail.

In the first half of the 19th century, the comets chiefly notable are those of 1811 and 1843. The former was a most brilliant object for many weeks in the northern heavens. It is periodic, though travelling at aphelion to the enormous distance from the sun of 40,121,000,000 miles. The latter was also remarkable for its brilliance, but chiefly for its very near approach to the sun, passing so near that a trifling change in its direction of approach would have caused a collision. Not more than 32,000 miles separated their surfaces when nearest. Its tail also was enormous, reaching in length 200,000,000 miles. Since 1850 many brilliant comets are recorded: Donati's in 1858; and the great comet of 1861, through the tail of which our earth passed on June 30th of that year.

with scarcely a sign observable of the passage; also Coggia's comet in 1874, remarkable for the series of envelopes of luminous matter which seemed to combine to form its tail. The great comet of 1880 astonished astronomers by following the same track as that of 1843, almost grazing the sun. That of 1881 iii followed the track of that of 1807, for a return of which it was at first mistaken. These two examples demonstrated that

in some cases several comets travel on the same orbit, at great distances, however, from one another. The comet 1881 iii was the first successfully photographed, Janssen obtaining a picture including $2\frac{1}{2}^\circ$, and Dr Henry Draper of New York one including 10° of its tail. Dr Huggins and Dr Draper were also both successful in photographing its spectrum, with results confirming what eye observations already had revealed. Dr Schäberle at Ann Arbor, Michigan, discovered another bright comet, the fourth for the year 1881, which for a time accompanied 1881 iii, both being in the northern heavens together. At Dudley Observatory, U.S., a comparatively small comet was discovered soon after by Mr Wells, remarkable as the first in whose spectrum the sodium line was seen. In 1882 the surprise of 1880 was repeated. Another bright comet appeared in September, following the tracks of the 1843 and 1880 comets, making the third in an orbital procession in space. It was seen in New Zealand on September 3, at the Cape of Good Hope on September 8, and at Rio de Janeiro on the 11th. Mr Common at London had been seeking for a short time to catch a bright comet near the sun in the daytime. Independently, on September 17, he discovered this one, close to and rapidly nearing the sun. Clouds prevented him from seeing the passage, but it was observed at the Cape of Good Hope by Messrs Finlay and Elkin, who were watching at the time. Passing in front of the sun, it disappeared from view, overpowered by the solar brilliance, to reappear shortly passing off the other edge of the disc. All next day it was clearly seen, only surpassed in brilliancy by the sun itself. Though it had passed so close to the sun, it experienced no retardation of speed, proving that very near the solar surface there can be no resisting medium of density to affect such a body. It was followed with the telescope to a distance from the earth of 470,000,000 miles. This long observation enabled its period to be well ascertained as about 700 years. It exhibited in a marked degree a tendency to disruption. 'Space appeared,' says Miss Clerke, 'to be strewn with the filmy debris of this extraordinary body all along the track of its retreat from the sun.' Its tails corresponded to types 1 and 2 (see *post*), and there was a vast outburst of luminous matter in October towards the sun, having a diameter of 4,000,000 miles. Its spectrum showed the sodium line in addition to the usual cometary bands. The year 1883 was barren in cometary results; 1884 saw three new comets discovered respectively in Tennessee, Australia, and Europe by Barnard, Ross, and Wolf. In 1885, on the 27th November, there was a grand display of the meteors into which Biela's comet is now generally considered to have broken up; 50 to 60 a minute being recorded. Brooks, of Phelps, New York, discovered a comet on August 31 in that year. But in the next year (1886), within two months, three comets

rewarded this diligent observer, a record equalled in 1887 by Barnard, of Nashville, Tennessee. In 1888 comets were discovered by Sawerthal on February 18, and by Brooks, New York, on August 7. The returns of Encke's comet and of Faye's comet also mark that year. Some important results have flowed from those recent appearances, which find their place in the following summary of the most reliable explanation of cometary nature and behaviour.

Comet of 1811.

The quantity of matter in even the largest comet is known to be very small, $\frac{1}{1000}$ or so of that of the earth in a calculated instance, much less probably in many others. The nucleus, in which most of this is contained, is generally admitted to be a more or less close congeries of meteoric fragments. This is shown by the smallness of its mass as compared with its size, its spectrum, and the fact that comets and meteors follow one another in similar orbits.

Donati's Comet, 1858.

Biela's lost comet is now probably scattered into the meteor stream which pursues its track (see *ante*). The close agreement of cometary and meteoric orbits may appear from the fact that Tempel's comet (1866) has a period of 33.28 years, and the three groups of November meteors, following the same line, periods respectively of 32.25, 33.31, and 33.11 years. Also just as these groups follow one another in procession round the sun, so do the comets above mentioned of 1843, 1880, and 1882. Other systems of mingled comets and meteors are also known, and the spectroscopic researches of Lockyer may be said to have demonstrated that the peculiar spectrum of comets can be produced from meteors. Carbon, hydrogen, and sodium have been shown to enter into the composition of cometary nuclei. A banded spectrum of a hydrocarbon is the usual type, the sodium line only showing when the nucleus is close to the sun, and sweeping rapidly past it in a state of great disturbance. Usually as the nucleus nears the sun, it appears disturbed; then jets or masses of luminous material, gas or fine dust, are thrown up. Some repulsive force appears to seize these and

Biela's lost comet is now probably scattered into the meteor stream which pursues its track (see *ante*). The close agreement of cometary and meteoric orbits may appear from the fact that Tempel's comet (1866) has a period of 33.28 years, and the three groups of November meteors, following the same line, periods respectively of 32.25, 33.31, and 33.11 years. Also just as these groups follow one another in procession round the sun, so do the comets above mentioned of 1843, 1880, and 1882. Other systems of mingled comets and meteors are also known, and the spectroscopic researches of Lockyer may be said to have demonstrated that the peculiar spectrum of comets can be produced from meteors. Carbon, hydrogen, and sodium have been shown to enter into the composition of cometary nuclei. A banded spectrum of a hydrocarbon is the usual type, the sodium line only showing when the nucleus is close to the sun, and sweeping rapidly past it in a state of great disturbance. Usually as the nucleus nears the sun, it appears disturbed; then jets or masses of luminous material, gas or fine dust, are thrown up. Some repulsive force appears to seize these and

sweep them out into space with enormous rapidity, producing the splendid phenomena of the tail. The researches of Olbers, Bessel, Norton of Yale College, U.S., C. F. Pope, Zöllner, and especially Professor Bredichin, late of Moscow Observatory, have gone far to establish the existence of this force, and to identify it with electric repulsion. Professor Bredichin has divided comets' tails into three classes, those of hydrogen, of hydrocarbons, and of iron, due respectively to a repellent force (1) of 12 times solar gravity, (2) equal to it, and (3) $\frac{1}{2}$ of it. The first material and force give straight, the second slightly curved, and the third strongly curved tails. The comet, 1886 f, showed three tails, one corresponding to each of these types. Observation and calculation have verified these conclusions as to the forces, and forms of tails, but not yet as to the electric nature of the forces. The light of comets is mainly due to electric discharges; a part, however, is reflected solar light, and a part perhaps due to incandescence. The tenuity of comets' tails is inconceivable to us, stars, which the slightest fog would conceal, shining clearly through a thickness of millions of miles of their material. Hence, although so great a display is caused by the matter swept away from the comet at perihelion, it loses but little in apparent bulk, though in the course of centuries the loss is abundantly perceptible. Some comets, Professor Kirkwood suggests, are probably asteroids, thrown out of their proper track by the disturbing force of Jupiter.

Comets have been alternately regarded with terror and with welcome in the popular mind. The appearance of Halley's comet in 1456, just as the Turks had become masters of Constantinople, and threatened an advance into Europe, was regarded by Christendom with a superstitious dread, and to the Ave Maria was added the prayer: 'Lord save us from the devil, the Turk, and the comet.' At Constantinople the occurrence of a lunar eclipse at the same time increased the portentousness of the event. The discoveries of science of the magnitude of the space filled by their bodies, and their prodigious velocity, together with the confessed impossibility of always predicting their approach, produced fears of another kind, which have sometimes been, especially in France, extravagantly exaggerated in the public mind. The groundlessness of such alarms, from the extreme improbability of collision with the nucleus, the innocuousness of a contact with the extremely attenuated surrounding matter, and, possibly, to the greater part of the world, of a collision with the nucleus itself, will be sufficiently evident from what has been said above. It is certain that already, on many occasions, some of the attenuated vapour in the tail of comets must have come within the earth's attraction, and been absorbed in its atmosphere. Whether the effect is deleterious or salubrious, or whether it has any perceptible influence at all, is only matter of speculation. The salubrity of cometary influence is now a popular idea; and the vintages of 1811 and 1858 were favourable seasons, whose produce has been advertised as the comet wines. It is scarcely worth while, however, to follow further speculation on these subjects, and it has been considered preferable to confine this article chiefly to the description of the general characteristics of comets, and the facts respecting them afforded by science.

Comfrey (*Symphytum*), a common palaearctic genus of Boraginaceæ, somewhat coarse perennial herbs, although occasionally to be seen in flower-borders. *S. officinale* (blue) and *S. tuberosum* (yellow) are frequent in shady and moist places. *S. officinale* was formerly much esteemed as a vulnerary. Its young leaves and its blanched shoots are still occasionally used as boiled vegetables. The Prickly Comfrey (*S. aspernum*),

a native of Siberia, 6-10 feet in height, has been recommended for feeding cattle. The stamens are covered in this genus by five awl-shaped processes pushed in from the outside of the corolla, and meeting so as to form a false bottom impassable to ants, flies, and other small honey-thieves, but which can be thrust aside by the

Comfrey (*Symphytum officinale*).

humble-bees which alone fertilise the flower. Many bees, however (especially *B. terrestris* and one or two others), prefer to bite a hole in the side of the corolla below this cover, and the flowers may thus be seen to be visited both in the legitimate and illegitimate way. See FLOWERS (FERTILISATION OF).

Comines, a town on the borders of Belgium and France, 15 miles SW. of Courtrai by rail, divided by the Lys into two parts, of which that on the left (pop. 4381) belongs to Belgium; the other, on the right (pop. 6355), to France. The town has some manufactures, and was the seat of the family of Comines.

Comines, PHILIPPE DE, Sieur d'Argenton, a French statesman and historian, who was born about 1445—at Renescure, in the neighbourhood of Hazebrouck. His ancestors had been citizens of Ghent. He joined the court of Burgundy, and was sent by Charles the Bold on important missions to France, England, and Spain. In 1472 he forsook Charles and entered the service of Louis XI. of France. He was rewarded with the rich fief of Talmont, and became one of Louis's most trusted advisers. On the accession of Charles VIII. he was deprived of Talmont, and cast into prison for having incurred the displeasure of the regent, Anne of Beaujeu. He accompanied Charles VIII. on his Italian expedition, was present at the battle of Fornovo, and had an interview with Machiavelli in Florence. He held sundry places and pensions under Louis XII., and died in 1511. His *Mémoires* consist of seven books, six of which deal with the reign of Louis XI., while the seventh treats of Charles VIII.'s wars in Italy. They are the earliest example in

French literature of the history as distinguished from the chronicle. Unlike the chroniclers, Comines cares little for the mere spectacle of courtly and military life. His sympathies are with the king against the nobles; his interest is centred in statecraft; he takes a keen delight in seeing the game of politics well played. His reflections on men and affairs are always dispassionate, and often pregnant and acute. A number of his *Lettres et Négotiations* have been preserved and published (2 vols. Brussels, 1867-68). The best edition of the *Mémoires* is that edited by Chantelauze (Paris, 1881).

Comi'so, a town of Sicily, 37 miles WSW. of Syracuse, with manufactures of soap and pottery. Cotton is largely grown here. Pop. (1881) 19,333.

Comitia were the legal or constitutional meetings of the Roman people, convened by a magistrate, usually for the purpose of putting a question to the vote. According to the constitution of the several gatherings, they were *comitia curiata*, *comitia centuriata*, or *comitia tributa* respectively. See **ROME**.

Comity of Nations—more frequently mentioned by its Latin equivalent, *comitas gentium*—is the international courtesy by which effect is given to the laws of one state within the territory and against the citizens of another state. 'In the silence of any positive rule,' says Story, 'affirming, or denying, or restraining the operation of foreign laws, courts of justice presume the tacit adoption of them by their own government, unless they are repugnant to its policy or prejudicial to its interests.' See Story's *Conflict of Laws*; and **INTERNATIONAL LAW**.

Comma, in the mathematical study of sound, is a small interval, generally corresponding to the vibration-ratio 81 : 80, which occurs between the true pitches of two notes, which on the piano, organ, and other tempered instruments, are represented by one only. See **TEMPERAMENT**.

Commandant is the officer, of whatever rank, in command of a fortress or military post of any kind—e.g. a station on the lines of communication of an army. The title is also given to an officer commanding a larger body of troops than is proper to his rank, as captain-commandant, lieutenant-commandant, &c., and to the senior lieutenant-colonel of a volunteer battalion in the British army, where there are two or more on its establishment. There are also commandants to most military schools.

Commander, in the British navy, is an officer next under a captain in rank, and serves either as second in command in a large ship, or in independent command of a smaller vessel. In matters of etiquette, he ranks with a lieutenant-colonel in the army, but junior of that rank; and he bears the title of captain by courtesy. There were, in 1888, 160 commanders employed, with pay of £1 per day; while there were 69 on half-pay, but eligible for re-employment, and 347 on retired pay; but the whole list of those employed, or eligible for employment, is to be raised to 270. Retirement is optional at the age of forty-five; and compulsory at fifty, or after five years without employment. In the United States navy, commanders have a rank next below that of captain, and next above that of a lieutenant-commander, and rank with lieutenant-colonels in the army.

Commander-in-chief is the highest staff appointment in the British army. After the death of the Duke of Wellington in 1852, this title, which had been borne by him for many years, was allowed to lapse, and the administration of the army was placed under a general on the staff who was styled the general (or field-marshal, if of that rank) com-

manding in chief. Field-marshal H. R. H. the Duke of Cambridge was selected for this office, and in 1887 was created commander-in-chief by patent in recognition of his fifty years' service in the army, thus reviving the former title, without, however, making any change in his duties.

Since 1855 the commander-in-chief has been strictly subordinate to the Secretary of State for War. His office, technically called the **Horse Guards**, is the military department of the War Office (q.v.). At its head is the adjutant-general, and its several branches are presided over by the quartermaster-general, the military secretary, the inspector-general of fortifications, the directors of artillery, of military intelligence, of the army medical department, and of military education, the chaplain-general, and the principal veterinary surgeon. All promotions and military appointments are recommended by the commander-in-chief, those of great importance being supervised by the war minister, and, if necessary, discussed by the cabinet. He is responsible for recruiting operations, the technical education of officers and men, and everything connected with the efficiency, distribution, and mobilisation of the troops, together with the construction and armament of fortifications. He exercises an inspectional control over the men who are under the immediate command of the general officers commanding the various districts.

There is also a local commander-in-chief in India, under whom all the forces there are placed, and in many of the colonies the governor bears this title. It would also be given to the officer in command of any large army engaged in active operations. The powers of these officers extend only to those troops that may be placed under them by orders from the commander-in-chief at the Horse Guards.

A *naval* commander-in-chief is the chief admiral at any port or station. In the United States the president is *ex officio* the commander-in-chief of the army and navy.

Commandery, the district under a *commander*, specially used in connection with the Templars (q.v.), the Hospitallers (q.v.), and other religious orders.

Commandite, **SOCIÉTÉ EN, or PARTNERSHIP IN**, an expression used for at least two centuries in France, to express a partnership in which one may advance capital without taking part in the management of, or incurring further liability in connection with the business. The term 'sleeping partner' used in this country would nearly express the same idea, were it not for the attendant unlimited liability. The phrase is derived from the old meaning in the commercial nomenclature of France of the word *commande*, which was applied to the authority given to one person to transact business for another. The working partner had a *commande* from him who merely advanced capital. The term has acquired importance in political economy, because the law of France exempts the sleeping partners from responsibility beyond the amount they agree to be responsible for. On the other hand, by the law of the United Kingdom, every member of a partnership is liable for all its debts; limitation of liability being only obtainable by incorporation under the Companies Acts. Hence, in the discussions about the question, whether it would be prudent to relax this law, and permit persons to invest money in trading companies without undergoing this responsibility, such companies were called 'partnerships in commandite.' Proposals have from time to time been made in Britain to establish a system of limited partnerships independently of the Companies Acts. The Act 28 and 29 Vict. chap. 86, 5th July 1865, permits loans to trading firms in consideration of a

share of the profits, without involving partnership liability. The contract must be in writing, and the lender ranks in a bankruptcy after other creditors.

Commelyna'ceæ, an order of petaloid monocotyledons, all herbaceous, chiefly neotropical, of which a few species are cultivated in herbaceous borders on account of the beauty of their flowers, notably spiderwort, or *Tradescantia* (*Virginica*, and other species), *Commelyna cælestis*, &c. Others are grown in hothouses, notably the peculiar *Cochlostemma*.

Commemoration, or ENCENIA, the great festival of the Oxford academic year, usually takes place on the third Wednesday after Trinity Sunday. It is of very ancient date, public exercises and recitations having been held from time immemorial in honour of the Act, or period when Masters of Arts and Doctors complete their degrees. The proceedings consist of a Latin oration in honour of founders and benefactors; the presentation of the honorary degree of D.C.L. to strangers eminent in science, politics, &c.; and the recitation of the Newgate or English prize poem, the Latin prize poem, and the Latin and English prize essays. The more strictly academic and solemn portion of the proceedings was frequently wont to receive scanty attention from a great part of the audience; and the noisy humours of the gallery have often encroached on the stately periods of the public orator. In 1876 the undergraduates were removed from the special gallery they had hitherto occupied, and distributed amongst the general audience, which includes ladies and strangers as well as members of the university. 'Commencement' is the corresponding festival at Cambridge, where, however, it is of less general observance.

Commendam, an ancient manner of holding ecclesiastical benefices. When a living fell vacant by the preterm of its holder, it was *commended* by the crown to the care of a clerk, usually a bishop in one of the poorer sees, to hold till a proper pastor was provided for it. Such a living was called an *ecclesia commendata*, and was said to be held *in commendam*. A commendam in ecclesiastical law may be defined as the power of receiving and retaining a benefice contrary to positive law, by supreme authority. Holdings in commendam were abolished in 1836.—**COMMENDATORS**, in Scotland, in Roman Catholic times, were stewards appointed to levy the fruits of a benefice during a vacancy. They were mere trustees; but gradually the pope assumed the power of appointing commendators for life, without any obligation to account. This abuse led in 1466 to a prohibition of all commendams except those granted by bishops for six months and under. See ABBOT.

Commensalism (literally, 'at the same table'), the intimate, but never parasitic association of two different kinds of organisms, for the benefit of one, or very often of both. Of such advantageous partnerships there are so many different forms and degrees, that no precise definition of the term can be given. (1) Every one who has looked at shore animals must have observed how often mollusc shells, for instance, are covered with sponges, hydroids, worm-tubes, acorn-shells; and the like. But this is a purely external association, and depends simply on the fact that the shells afford convenient anchorage for the free-swimming embryos. In many cases no great advantage can accrue on either side. The habit is comparable to that of vegetable epiphytes upon trees. This grade might be spoken of as mainly external and unadvantageous association. (2) In other cases, however, the association, though probably accidental, brings its reward. When one sea-mat (Polyzoa) grows entangled with another of greater

vigour, or when different kinds of polyps are similarly associated, and that is often, there may be distinct advantage to the weaker form, since without becoming a parasite it enjoys the privileges of a messmate. Or the advantage may take another form, when the associate is carried about by its bearer. Thus, Cirripedes are common upon whales, and have evidently an advantage both in security and continual freshness of feeding-ground over those which adhere to fixed objects. This grade might be distinguished as that of fixed external associates with the advantage on one side. (3) It is, however, evident that if a crab be covered with acorn-shells, or polyps, or sponges, there is no longer a one-sided, but a mutual advantage. It is well for the sedentary growth to be carried about continually to new pastures; but it is well also for the crab to be masked. Covered with a rich growth, either vegetable or animal, the crabs must appear all innocence, and like walking-woods of Birnam, can steal unnoticed upon their victims. A gasteropod may be similarly masked by polyps, and doubtless gives and reaps similar advantages. This grade may be described as that of fixed associates with mutual advantage, to this extent, at least, that the weaker animals are borne about, and the bearers are masked. (4) But a higher stage of fixed association is sometimes exhibited, that, namely, where the partnership is deliberate, where the masked bearer is not passively benefited, but is an active accomplice. Probably the most striking case of such deliberate partnership is that referred to (and illustrated) under the article ANEMONE—viz. the habit which some hermit crabs have of bearing about sea-anemones on the mollusc shell which they inhabit, or even upon their claws. It would appear that in some cases the crustacean deliberately chooses its ally, induces it to fix itself on the shell or claw, and takes care not to leave it behind at the epochs of shell-changing. When deprived of its commensal, the crab is said to be restlessly ill at ease until another of the same species is forthcoming. Off some parts of the British coast, the beautiful sea-anemone (*Adamsia palliata*) is found enveloping the mollusc home of a hermit crab (*Eupagurus prideauxii*). The use of the sea-anemone as a mask, and also as equivalent to a stinging organ, is obvious enough, while the hermit crab returns the benefit by carrying about the sea-anemone and giving it a share of the spoil. This grade may therefore be described as deliberate partnership with mutual advantage.

So far only fixed commensals have been spoken of, but organisms may be constantly associated without being attached. Sometimes different organisms, both plant and animal, are found in almost constant association without any obvious connection obtaining between them. In many cases this companionship may be simply due to the fact that similar environmental conditions suit both. Small fishes are sometimes found as free commensals within sea-anemones; the Remora (q.v.) attaches itself temporarily to sharks and other fishes; the little crabs (Pinnotheres, &c.) found living freely inside various bivalves are probably true messmates, and similar habitual partnership is very common among crustaceans; a brittle-star is known to live as a free messmate on a crinoid; many worm-types are found in constant though free associations with other animals; and the same habit is exhibited by some Coelenterates and Protozoa. Many of the insects which frequent plants are in strict sense commensals, feeding not on their hosts, but on other visitors, &c. In some cases they form an actual bodyguard.

Commensalism must, of course, be distinguished from Parasitism (q.v.), whether external or internal,

for in parasitism the one organism more or less directly preys upon the other. Yet it is evident that a commensal may readily degenerate into a parasite. Commensalism must also be distinguished from that most intimate kind of partnership known as Symbiosis (q.v.), and illustrated by the union of algoid and fungoid organisms to form a lichen, or by the occurrence of algae as constant internal associates of Radiolarians, some Coelenterates, and some worm-types.

As part of the animate environment, commensals have influenced one another in very direct ways. See ENVIRONMENT; P. J. van Beneden's *Animal Parasites and Mesmates* (1876); and Seimper's *Animal Life* (1881).

Commensurable. Two quantities or numbers are said to be commensurable which are of the same kind, and each of which contains a third quantity or number a certain number of times without remainder; or when both can be measured exactly by the same unit, however small.

Commentrey, a town in the French department of Allier, 211 miles S. of Paris by rail, is close to a great coal-field, and owes its rise to coal and iron works. Pop. (1886) 9233.

Commerce, CHAMBER OF. See CHAMBER OF COMMERCE.

Commercial Law. See MERCANTILE LAW.

Commercial Travellers. A commercial traveller ('C.T.') is a person whose occupation is to transact business as the accredited travelling representative of a trading house to other trading houses. A further qualification is insisted upon by benevolent institutions connected with the body, in the rule that a traveller must have been 'on the road' for two years before he can claim benefit. A 'townsman' or 'town traveller' is one who confines his efforts to a single town. In thirty years a fourfold increase in the number of commercial travellers is shown by the annexed statistics: In 1851 there were in England, 8378; in Scotland, 1017; in Ireland, 339; total, 9734. In 1881 there were in England, 35,570; in Scotland, 4793; in Ireland, 1558; total, 41,921. In the latter year, 878 of the total number were European foreigners; but at the present there is doubtless a much larger proportion. The death-rate of commercial travellers in 1881, though it shows a considerable improvement on that of 1871, was high (34 per 1000), or nearly 50 per cent. above that of persons engaged in agricultural pursuits. A very large proportion of deaths was due to diseases caused by intemperance. To this terrible scourge must also be attributed the fact that the number of suicides is higher in this than in any occupation save one. Happily, of late years a marked improvement is noticeable, owing to the spread of temperance principles and an increased number of temperance hotels.

Of the later half of the 18th century in Britain 'many districts remained completely excluded, so that foreign products never reached them at all,' and 'even at the beginning of the 19th century the Yorkshire yeoman was ignorant of sugar, potatoes, and cotton.' It has been the work of the commercial traveller to materially assist in altering this state of things, and to bring about 'equality of distribution of produce, and corresponding equality of prices, and generally to promote that 'facility of exchange which is the very soul of industry.' Commercial travelling in the specific sense is not an old institution. The 'commercial traveller,' 'bagman,' or 'rider' (in the United States, 'drummer') was the successor to the 'chapman' or travelling merchant, who carried with him not samples merely, but stock. Chaucer tells us that:

In Surrye whylom dwelte a compayne,
Of chapmen riche, and therto saddle and trewe,
That wyde wher senten her spycceris,
Clothes of gold, and satins riche of hewe.

The application of steam to machinery, the consequent rise of the factory system, increased facilities in banking, and improved means of locomotion, have made the commercial traveller an important factor in the commercial world. Within recent years a formidable competitor has entered the field in the person of the foreigner, whose superior education and commercial training have hitherto placed the British commercial traveller at a disadvantage. A further development of commercial travelling is before us; there is room especially for men possessing a thorough knowledge of foreign and colonial trade, and above all of modern languages.

There are several excellent institutions connected with the body, owing largely to the efforts of men like George Moore and George Stockdale. The Commercial Travellers' Schools for destitute orphans and necessitous children were founded in 1845: the school at Pinner accommodates 360 children. The Commercial Travellers' Benevolent Institution was founded in 1849 for the relief of necessitous commercial travellers over the age of fifty-five years, being members, and for their widows. The relief is given in the form of an annuity of £50 to members, and £30 to their widows. The Commercial Travellers' Society of Scotland was founded in 1838 for the relief of members incapacitated by disease, accident, or infirmity, and for securing a payment at death. The British Commercial Travellers' Provident Society, like the last named, is based on the Friendly Societies Act. There is also a Commercial Travellers' Christian Association (1882); and the United Kingdom Commercial Travellers' Association (1883) has done good work in pushing forward hotel and railway reforms, and in promoting social intercourse among commercial travellers. A newspaper, *On the Road*, devoted entirely to the interests of commercial travellers, was established in 1883.

In the United States the number of commercial travellers has increased rapidly, till in 1888 it was computed that there were between 230,000 and 300,000. Amongst their benevolent associations are the Commercial Travellers' Association of New York (2000 members); the North-western Travelling Men's Association of Chicago (4000); one at St Louis (2100); an Order of Commercial Travellers, a secret society organised in 1888; also a Travellers' Protective Association (9000 members), for providing against overcharges by railroads and hotels, &c. The organ of the travelling salesman is *The Merchant Traveller*, published at Chicago.

Commination (Lat., 'threatening'), the 'denouncing of God's anger and judgments against sinners,' read in the Anglican Church on Ash-Wednesday (q.v.). A solemn service, at which penitents were expelled from the church, after instructions and prayers for their amendment, appears to have been held on the first day of Lent from a very early date, perhaps from the beginning of the 6th century; but the commination office used in the Church of England is rather a continuation of the medieval practice of reciting the 'articles of the sentence of cursing,' which were at one time read in the parish churches four times a year; only the opening exhortation to repentance was composed by the English Reformers. The present office is nearly the same as those found in the Sarum and York uses. The curses contained in Deut. xxvii. are read as statements, not as prayers; and the congregation answer 'Amen' to every sentence, as acknowledging the truth of what has been stated, rather than as confirming the curse. The American

Prayer-book omits this office, but several prayers taken from it are appointed to be said on Ash-Wednesday, at the end of the litany.

Commissariat is a name for the organised system whereby armies are provided with food, forage, fuel, quarters, and all other necessities except warlike stores. In feudal times, soldiers were mainly dependent for food on their lords; but they lived very much by plunder. During the wars of the Crusades, the commissariat was so utterly neglected that thousands died of starvation.

The first germ of the modern British commissariat appeared in the office of *proviand-master* in the time of Queen Elizabeth. Under Charles I., commissaries were stationed in the different counties. Marlborough's troops were supplied by contract; he received a percentage, and peculation was very common. After many changes during the 18th century, a commissary-general was appointed in 1793 to superintend all contracts for food and forage. The dire experience of the Crimean war showed how inadequate the small existing establishment was to bear the strain of a campaign. In 1858 and 1859 the commissariat was newly organised; and remained, until 1870, a War-office department, under a commissary-general-in-chief.

In 1870 it was merged with other supply departments in the great 'Control Department,' which, under the Surveyor-general of the Ordnance, performed all the civil administrative duties of the army, until its abolition in 1875. The 'Commissariat and Transport Department' was then formed, and administered by the Director of Supplies, an officer on the staff of the Surveyor-general at the War Office, the supply of warlike stores being placed under the Ordnance Store Department (q.v.). The reorganisation of the War Office in February 1888, while leaving the duties of these two departments unaltered, has placed them under the Quartermaster-general. In India this has always been the case so far as the commissariat is concerned, which is officered by appointments from the combatant branch. The present British staff consists of 2 commissaries-general ranking as major-general, 10 deputy-commissaries-general with honorary rank of colonel, 62 assistant and 111 deputy-assistant commissaries-general with honorary rank of major and captain respectively, 40 quartermasters (honorary lieutenants), 3 adjutants, 1 paymaster, and 2 riding-masters. Their pay varies from 9s. 6d. a day in the lowest ranks to £1500 a year in the highest. There are 37 companies, having each a peace establishment of 2 officers, 123 of other ranks, 63 horses, and 12 wagons.

The war establishment laid down in 1888 for a commissariat and transport company with an infantry brigade is 5 officers, 192 non-commissioned officers and men, and 234 horses, and if with the headquarters of a division of infantry, 7 officers, 157 of other ranks, and 184 horses. The establishment for an Army Corps (q.v.) in the field, with three days' rations for the men, and two days' forage for the horses, is 60 officers, 2494 non-commissioned officers and men, 2796 horses, and 438 carriages. The wagons of the Army Medical and Ordnance Store Departments are horsed by the Transport Department. Camp equipment, fuel, forage, food, &c. are supplied by the commissariat, the actual cooking being done by the regimental cooks. Clothing is supplied by the government factory at Pimlico, and, like all other stores, brought to the army, if in the field, by the transport branch of this very important department.

The Indian commissariat is, as indicated above, a local department, varying in strength with the requirements of the moment. There is also a small local staff of 1 commissary, 3 deputies, and 1 assistant on the west coast of Africa.

In the United States the army commissariat is administered by a commissary-general of subsistence, having the rank of brigadier-general; five assistant commissary-generals, ranking as colonels and lieutenant-colonels; eight commissioners of subsistence, ranking as majors, and twelve as captains. Their salaries are from \$5500 to \$2000.

Commissary, in general, is any one to whom the power and authority of another is committed. An ecclesiastical commissary is an officer of the bishop, who exercises spiritual jurisdiction in distant parts of the diocese. A military commissary is an officer charged with furnishing provisions and clothes to an army.

When the papal authority was abolished in Scotland, a supreme commissary court was established in Edinburgh in 1563, by a grant of Queen Mary. This court had jurisdiction in actions of divorce, declarators of marriage, nullity of marriage, and all actions which originally belonged to the bishops' ecclesiastical courts. Its powers were gradually conjoined with those of the Court of Session, and it was finally abolished in 1836, the small remains of its once important jurisdiction being united in the sheriff of Edinburgh. See Alexander on *Practice of the Commissary Courts in Scotland* (1858), and Fraser on *Husband and Wife*.

Commission. As a commercial term, commission is sometimes taken to be synonymous with Brokerage, but there is a distinction. Brokerage is the percentage paid to a passive intermediary in a transaction, who incurs no responsibility; commission is the percentage paid to an active agent in a transaction, who usually does incur some pecuniary and always some moral responsibility.

A commission as a certificate of rank is granted by the highest authority of a state. All military and naval commissions in Britain must be signed by the sovereign; but in the United States a commission may be issued by a governor of a state as well as by the president of the republic, commissions in the volunteers (or militia) being generally granted by state governors. The appointment of justices of the peace in the United Kingdom is also made by a 'commission of the peace,' issued under the great seal. The great seal itself is in charge of a Lord-keeper, but is put 'into commission' when a change of ministers is taking place. This means that certain persons are appointed to exercise jointly, but without individual powers, the functions of the office. Another instance of the functions of a great public officer being delegated to others 'in commission' is that of the Lord High Admiral, who formerly had control of all naval affairs. This, however, is a permanent commission, although commissioners of Lords of the Admiralty change with every change of the ministry.

An office in commission is an office in suspense. Yet, curiously enough, the phrase has a directly opposite meaning in naval affairs, for when a ship is ordered to be placed 'in commission,' it means that she shall be fully equipped and prepared for active service.

Permanent commissions are also constituted, not merely for the delegation of existing duties, but also for the execution of duties with which no person had been previously charged. As instances we may take the Civil Service Commission in 1855 (see CIVIL SERVICE); the Railway Commission, appointed in 1873 to carry out the act for the better regulation of railways passed in 1854, and to otherwise act as a sort of court of arbitration or appeal in disputes between railway companies; the Irish Land Commission, appointed to carry out some of the provisions regulating the land laws in Ireland; the Crofters Commission, appointed for five years from 1886 to fix fair rents for the Scotch

crofters. The members of these are nominated in terms of special acts of parliament.

Other permanent commissions are the Charity Commission, created 1853 (of four members, one of whom is unpaid), to examine into all the charities and the management of them, in England and Wales; the Commission for the management of the National Debt; the Ecclesiastical and Church Estates Commission; the Land Commission of England; the Public Works Loan Commission; the Thames Conservancy Commission; and the Commission for the adjustment of Cases under Income-tax Assessments. These are all bodies commissioned to execute certain specified functions, more or less administrative, and partaking to some extent of the character of public departments.

In law, a commission may be issued by mandate of a court to take evidence from parties residing abroad or incapacitated from appearing in person. A Commission in Bankruptcy is issued for the purpose of taking charge of the effects of an insolvent for behoof of his creditors. A Commission in Lunacy is appointed by the Court of Chancery to inquire into the mental condition of an alleged lunatic whose property may be in question. There are now permanent commissioners in lunacy whose duties include visitation and supervision of asylums.

In governmental relations, commissions are sometimes constituted where Britain exercises protectorate but has not formed complete colonial establishments, as in Cyprus, South Africa (see CAPE COLONY), New Guinea, and some islands of the western Pacific. The commission in such cases is a delegation, with certain limitations, of the authority of the crown. In India (q.v.) the administrative head of a province is sometimes called chief-commissioner (assisted by district commissioners), who is responsible to the viceroy of India. Sometimes commissions are international—i.e. composed of representatives of various nations for international purposes. A conspicuous example of such was the commission in 1871 on the Alabama question (see ALABAMA); more recent was the commission for Eastern Roumelia, appointed under the Treaty of Berlin of 1878.

Again, a commission may take the form of a temporary embassy for certain specific purposes. The appointments are then made by the prime-minister and cabinet, as when Mr Gladstone was sent to the Ionian Islands in 1858, or Lord Dufferin to Egypt in 1883. Somewhat different in character was the commission given to Mr Chamberlain in 1887 to proceed to America, to confer with delegates of Canada and the United States upon matters in dispute concerning the fisheries.

In its parliamentary sense, a commission may be either Special or Royal. In the former case it is appointed usually, and in the latter case invariably, in response to a motion in one or other of the Houses. A royal commission is appointed only by the crown; but a special commission may be appointed by a department of state. The expenses of a commission of this kind are usually defrayed by the parties requiring it, but those of a royal commission are included in the estimates for the current year. The commissioners may be paid by fees regulated by government. When a commission sits in London, it has the power of authorizing the payment of witnesses on the scale recognised in courts of law; but when a commission sits in the country, witnesses are not paid.

A royal commission is appointed by motion in parliament, and is issued by a royal warrant nominating certain 'trustworthy and well-beloved counsels and counsellors' to undertake a specified inquiry. Of such was the royal commission to inquire into the condition of the crofters (1882),

which was a wholly different body from that appointed by act of parliament in 1886 to carry out certain legislative decrees. The former was one of inquiry; the latter, one of administration. The royal commissions appointed to inquire into the causes of the depression of trade (1886-87), and into the recent changes in the relative values of the precious metals (commonly called the Silver Commission), also in 1886, are among the most prominent of recent appointments of this kind.

When a royal commission is nominated by royal mandate, a secretary is appointed, and such clerical assistance as may be necessary is provided out of some of the departments. The commissioners are empowered to call and hear evidence (although not on oath), to examine documents, localities, &c. The evidence is reported *in extenso*—question and answer duly numbered—and is submitted, along with the formal report, to the sovereign and to parliament. The whole is then incorporated in a blue-book. The multiplication of royal and special commissions has become rather a legislative nuisance and a financial burden. Royal commissions always include members of the House of Lords or of the House of Commons, or of both, but not exclusively, for any qualified person may be nominated by the sovereign at the advice of the ministry.

The cost of parliamentary and royal commissions in the fiscal year ending 31st March 1888 was as under:

Charity Commission.....	£36,701
Civil Service Commission.....	44,477
Land Commission of England.....	12,210
Lunacy Commission of England.....	15,217
Scotland.....	5,990
Public Works Loan Commission.....	9,533
National Debt Commission.....	15,071
Wreck Commission.....	12,680
Crofters Commission.....	6,831
Land Commission of Ireland.....	45,912
Endowed Schools Commission.....	700
Temporary Commissions.....	33,404

Another kind of commission is that sometimes given to two or more judges to inquire into certain alleged crimes, such as the commission (1867-69) to inquire into the Sheffield trades-union outrages, and that of three judges appointed by act of parliament in 1888, to inquire into the 'charges and allegations' brought in the *Times* newspaper against Mr Parnell and others.

It should be added that the sovereign, who nominally presides over the annual deliberations of the General Assembly of the Church of Scotland, delegates the duty to a Scotch peer as Lord High Commissioner, a fresh commission being issued every year. For the ecclesiastical court created by Queen Elizabeth, see HIGH COMMISSION.

Commission Agent, or **MERCHANT**, is a person employed to sell goods consigned or delivered to him by another who is called his principal, for a certain percentage, commonly called his commission or factorage. See **BROKER**.

Commissionaires is a name given to a class of attendants at continental hotels, who perform certain miscellaneous services. Employed to attend at the arrival of railway trains and steamboats to secure customers, they wait to take charge of luggage, see it passed through the hands of the custom-house officers, and send it on to the hotel; for all which service they charge a fee.

In 1859 the *Corps of Commissionaires* was established by Sir Edward Walter in England, with divisions in London, Edinburgh, Glasgow, Leeds, Liverpool, Manchester, and other large cities in the United Kingdom. The corps has recently extended its operations to the principal cities of Australia, and purposes to continue its further development throughout the colonial empire. The corps is composed of picked men from every branch of Her

Majesty's naval and military service, and in the London division alone there are 1200 men. They can be engaged by the day or any other period, and for any duty where honesty, sobriety, and intelligence are required. The wages range from twenty to forty shillings per week.

Commission del Cr'ederé. See DEL CREDERE COMMISSION.

Commissioners of Supply. See SUPPLY.

Commissions, ARMY, are warrants from the head of the state for holding various military offices, whether combatant or non-combatant. The latter class comprises the various departments of the army, such as chaplains, commissariat, transport, veterinary, ordnance store, &c., in which, so far as the British army is concerned, commissions, carrying honorary or relative military rank, are obtained by direct examination, by nomination coupled with special professional qualifications, or by transfer from other branches of the service. Candidates for the Medical Staff (q.v.) pass through a course of instruction at the Army Medical School attached to the Royal Victoria Hospital, Netley, before being commissioned as surgeons. As regards the combatant officers, a first commission as sub-lieutenant can be obtained by any British subject of proper age, character, and physical qualifications, either by entering one of the Military Schools (q.v.) as a Cadet (q.v.), or by passing both a literary and a military examination (similar to that mentioned below for a lieutenant's promotion), after having served two trainings as an officer in the militia. All correspondence regarding first commissions or cadetships is conducted by the military secretary at the War Office. Commissions in the Royal Marines are obtained by direct competitive examination. Two or three sub-lieutenants' commissions are given each year to cadets from the Royal Military College of Canada. It is also possible to obtain such a commission by enlisting; but only two or three specially selected sergeants are promoted each year to the rank of sub-lieutenant in the cavalry and infantry (135 officers now serving have risen from the ranks), though all quartermasters, riding-masters, or officers of the Coast Brigade Royal Artillery, and Coast Battalion Royal Engineers, are commissioned, as lieutenants, from the ranks.

Subsequent commissions up to that of lieutenant-colonel are given, as vacancies occur, to the senior officer of the next lower rank, provided that he has been favourably reported on, and, in the case of a lieutenant or captain, has passed an examination for promotion in regimental duties, drill, fortification, tactics, military law, and topography. To assist officers in passing this test, a deputy-assistant adjutant-general for instruction is appointed to the staff of each military district, and classes are held under him for the study of the four last-mentioned subjects. The rank of colonel is only conferred by Brevet (q.v.) for distinguished service, or on appointment to certain positions carrying that rank, such as aide-de-camp to the Queen, assistant adjutant-general, or commander of a regimental district. Promotion to major-general, lieutenant-general, and general, is by selection, as vacancies occur. The establishment in these ranks has been much reduced, and only those who are eminently qualified, professionally and physically, are eligible for commissions in them.

Previous to 1st November 1871 all combatant commissions were purchased, except in the Royal Artillery, Engineers, and Marines, and a few given as prizes to those caulets who passed out of the Royal Military College at the head of the list. It was then also possible to qualify for a commission

by purchase, by passing a direct non-competitive examination. The lowest price of a first commission in the line was £450, the highest (in the Life Guards) was £1260. Large sums had also to be paid for each step in rank, so that the interest of the money thus invested sometimes exceeded the pay of the rank.

The entire abolition of the purchase system (by royal warrant in 1871) has at the same time increased the actual value of commissions as a means of livelihood, and the number of those who are in a position to compete for them. The competition has in consequence become very severe at the examinations, which are held usually twice a year, for admission to the two military colleges and for militia candidates for army commissions. To meet this, a large number of special educational establishments have been formed, devoted entirely to the work of preparing candidates for these tests, and most of the large schools have special army classes. The expenses thus entailed are often not much less than the cost of a first commission under the purchase system, but no further payment is incurred by promotion.

The subjects of examination for cadetships are selected, so far as the number of marks allotted to each is concerned, so as to encourage boys who have received the usual classical education, to come up direct from school without having to undergo a course of cramming at a military tutor's, where the influences are not always desirable. See CADET.

Commissure, an anatomical term applied to nervous connections between adjacent parts of the nervous system. Though it is not always used in quite the same way, the general signification of the term, and the physiological import of the structure, is that of a uniting bridge. See BRAIN, NERVOUS SYSTEM.

Commitment. See CRIMINAL LAW.

Committee (Fr. *comité*), a portion, generally consisting of not less than three members, selected from a more numerous body, to whom some special act to be performed, or investigation to be made, is *committed*. But though a committee usually consists of several members of the body by which it is appointed, it may consist of one member, or, what is more frequent, of the whole of the members acting in a different capacity from that which usually belongs to them. For the committees of parliament, whether 'select,' 'of the whole house,' 'grand,' or 'standing' committees, see PARLIAMENT.

Commodore, in the royal navy, is a rank intermediate between an admiral and a captain. It is not permanent, but is bestowed for a time on a captain. Usually a commodore commands more ships than one, detached from a fleet on some special service; he hoists at that time a white broad pennant, with a red cross, at the main if a commodore of the first class, at the fore if of the second class. A commodore is privileged to have a commander under him in his ship, in the same way as an admiral is privileged to have a captain. The commodore, in matters of etiquette, ranks with a brigadier-general in the army. When in independent command, a commodore of the first class receives £7, 10s. a day, and a commodore of the second class about £4, 10s.

Until 1862 the title of commodore, without any commission as such, was given in the United States navy to such captains as commanded, or had commanded, a squadron. In 1862 the rank of commodore became a commissioned one. A commodore ranks higher than a captain and lower than a rear-admiral. His rank is assimilated to that of a brigadier-general in the United States army.

Commodus, LUCIUS AURELIUS, a Roman emperor, born at Lanuvium in 161 A.D., was the son of the great Marcus Aurelius and his profligate wife, the younger Faustina. He was carefully educated under his father's care, but lived to become one of the most worthless and bloody wretches that ever disgraced a throne. At his father's death in the spring of 180, he was successfully fighting the Marcomanni and other tribes on the upper Danube, but he at once concluded a treaty with the barbarians, and hastened to Rome to enjoy the pleasures of power. After the discovery of his sister Lucilla's plot against his life in 183, he gave uncontrolled vent to the senseless savagery of his nature. Nearly all who, by virtue, ability, and learning, had risen to honour during his father's lifetime, were sacrificed to appease his savage jealousy of the good and the great. Proud of his own physical strength, he demeaned himself by exhibiting it in gladiatorial combats, and besides used, in public, to sing, dance, play, and act the buffoon. Though a glutton and a shameless debauchee, who wallowed in the most sensual abominations, he yet demanded to be worshipped as a god, and assumed the title of Hercules Romanus. Many unsuccessful plots were devised against the life of this mingled monster and madman, until at length his mistress, Marcia, finding her own name marked down in his tablets for death, in concert with two confederates, tried first to poison him, then caused him to be strangled by Narcissus, a famous athlete, on the 31st of December 192.

Common Bench. See BENCH, and COMMON LAW.

Commoner, one under the rank of nobility; also a member of the House of Commons. For the *Commoners* at Oxford, a class of students eating at the common table, see OXFORD.

Common Forms are the ordinary clauses which are of frequent occurrence in identical terms in writs and deeds.

Common Good. See BOROUGH.

Common Law, in England, is the ancient customary law of the land. Before the Norman Conquest, the rights of an Englishman were determined mainly by the customs of the manor, borough, or shire in which he lived. After the Conquest, the king's judges began to go their circuits in every part of the country, doing justice according to the custom of the realm or the common law. In some points they kept to the ancient local customs, in others again they introduced new rules. Primogeniture, e.g., is a rule introduced by the influence of the judges; the ancient English rule of equal division survives only as the 'custom of Kent' under the name of Gavelkind (q.v.). The custom of certain ancient boroughs, which gave the land to the youngest son, survives under the name of Borough English (q.v.). The custom of a place, or of a body of persons, is allowed to supplement or modify the common law if it has been observed from a time 'whereof the memory of man runneth not to the contrary.' Legal memory does not go back beyond the first year of the reign of Richard I., but evidence may be given to impugn the 'immemorial' character of a local custom by showing that it had its origin later than that year.

Even in making new rules, the judges never assumed to legislate; they professed to expound the good customs of the realm, and in applying the rules of common law, each generation of judges was guided by the decisions of its predecessors. Decisions followed in a series of subsequent cases acquired special authority, and were quoted as leading cases. The law fixed by custom and by judicial decision could only be set aside or amended by an act of parliament. But without setting aside

the law, courts of equity, and especially the Court of Chancery (q.v.), framed rules of their own, which enabled them to prevent the stricter rules of common law from being used in defence of injustice. By the Judicature Acts (q.v.), courts of common law and equity were made parts of one supreme court; the two systems are administered concurrently; where there is any conflict between equity and common law, the rules of equity prevail. See EQUITY.

English settlers going to an uncivilised country take with them 'as much of the common law as the nature of things will bear.' In Canada, Australia, &c., and in the United States, the historical basis of the law is the same as in England. In Scotland, and in some other countries, the term common law is used in a sense analogous to its English meaning.

THE COURTS OF COMMON LAW.—The superior courts of Common Law in England had their origin in the Curia Regis of the early Norman kings, the chief officers of which were the Chief-justiciar, the Chancellor, and the king's justices. The justices sat in the King's Bench to supervise the proceedings of inferior courts and corporations, and to deal with criminal matters directly concerning the crown. In the Common Bench or Common Pleas they held pleas between subject and subject. In the Exchequer they sat, as Barons of the Exchequer, to decide revenue cases. At first all these courts followed the king, to the great inconvenience of suitors. The Common Pleas were fixed at Westminster by Magna Charta; and in course of time the three superior courts of Common Law were all established on one side of Westminster Hall, each court having its own chief and four (afterwards five) puisne or junior judges, who were called justices in the King's Bench and Common Pleas, and Barons in the Exchequer. On the passing of the Judicature Acts (q.v.), the three courts became divisions of the High Court of Justice. The offices of Chief-justice of the Common Pleas and Chief-baron of the Exchequer are now abolished, and the three divisions are consolidated in the Queen's Bench Division. The Lord Chief-justice of England is the presiding judge; he is appointed by the crown on the advice of the prime-minister, and his salary is £8000. There are fourteen puisne justices, appointed by the crown on the advice of the Lord Chancellor, each of whom has a salary of £5000. The sittings of the Division are held at the Royal Courts in London; the judges also try cases on their circuits and at the Central Criminal Court. The jurisdiction of the Division includes all special authorities formerly belonging to any of the old Common Law Courts. It takes, e.g., appeals from Revising Barristers (q.v.) which formerly went to the Common Pleas, and revenue cases which belonged to the Exchequer. Appeals from any of the old Common Law Courts went to the judges of the other two courts, sitting in the Exchequer Chamber, and from them to the House of Lords. Appeals from the Queen's Bench Division now go to the Court of Appeal, and thence to the House of Lords.

Besides the superior courts, there are many inferior courts which exercise a limited common-law jurisdiction. Each manor has its own courts, but except in regard to Copyholds (q.v.), manorial jurisdiction has been superseded by local courts of modern origin. The same remark applies to the Hundred Court and the ancient County Court. The Court of Common Pleas in Lancaster and the Court of Pleas in Durham, now form part of the High Court. The modern County Court (which ought more properly to be called a district court) has a common-law jurisdiction; and several statutes contain provisions for remitting the less important

class of common-law actions to the County Court for trial.

Of Borough Courts some (as, e.g., the Court of Hustings in London) are obsolete; others (as, e.g., the Mayor's Court in London and the Court of Passage in Liverpool) are still of importance. The City of London Court is framed on the model of the modern County Courts. The Court of the Cinque Ports is held before the mayor and jurats of each port; from them appeals are taken to the Lord Warden's Court, and thence to the Queen's Bench Division. Courts of Request for the recovery of small debts existed in several boroughs; they are now obsolete, as also is the Court of Pie Poudre, or dusty foot, held by the steward of a manor to which a market belongs, for the immediate decision of questions arising in the market. There are still courts of some importance, established for the benefit of privileged bodies of persons. See, as to miners, STANNARY COURTS; as to Oxford and Cambridge, see UNIVERSITY.

Common Pleas. See COMMON LAW.

Common Prayer, BOOK OF. See PRAYER-BOOK.

Common-riding is the Scotch equivalent of Beating the Bounds. See BOUNDS.

Common Room, an apartment in a monastery in which a fire was constantly kept burning for the use of the monks, and which was presided over by a monk called the master. It was the prototype of the common rooms in the colleges of the English universities, where the dons take their wine after hall.

Commons, the dinner provided in English colleges and inns of court for their members. In the inns of court it is provided only during term. Separate tables are appointed for the Benchers (q.v.), for the barristers, and for the students and other members of the inn.

Commons, HOUSE OF. See PARLIAMENT.

Commons and Enclosures. This is one of the numerous instances in which a different meaning is attached to the same term in the legal systems of England and Scotland. In England the property in the common land belongs to the lord of the manor; although rights over the common land are possessed by certain persons who hold land in the manor, and are known as commoners. Thus Blackstone defines a common as 'a profit which a man hath in the land of another, as to feed his beasts, to catch fish, to dig turf, to cut wood and the like.' But in Scotland, where the law has adopted the divisions and followed the nomenclature of the civil law and of the legal systems of continental Europe, all these profits, or rights to derive profit, are known as *Servitudes* (q.v.), whereas a common, or commonity, as it is more frequently called, is a common right of property existing in several individuals, frequently the inhabitants of a whole village, in a piece of ground. In each individual the right of course is limited, so as in reality to amount to little more than a servitude; but there is no over-lord, the land is not the land of another, but the land of the community as a body.

The nature and origin of rights of common have been the subjects of elaborate investigation, but are still obscure. They are probably derived from the old Germanic rights of common pasture on the *Folkland* (q.v.). In England at present almost the only land subject to common rights is waste land; but formerly rights of joint cultivation extended over a great part of the arable land. These are not yet quite extinct. So long as the lands subject to rights of common were extensive and fertile, their enclosure was a source of wealth

both to lords of manors and to the nation as a whole. Accordingly enclosures began to be frequent in the 16th, and were continued on a great scale to the end of the 18th century. Formerly the enclosure of a common required a private act of parliament. The commoners, who were generally poor and unable properly to represent their case, often suffered by enclosure, obtaining inadequate compensation. By the Act 6 and 7 Will. IV. chap. 115, and subsequent acts, the necessity for a private act of parliament is abolished. By the Act 8 and 9 Vict. chap. 118, which has been often amended, a Board of Commissioners is appointed to inquire into the propriety of any proposed enclosure or partition, and to report to parliament, which may then pass a public act authorising their proceedings. This is the course generally adopted.

In Scotland, commonities or commons were made divisible by an action in the Court of Session, at the instance of any person having an interest by the Stat. 1695, chap. 38.

The lands still subject to rights of common are for the most part such as could not be cultivated with advantage. The increase of population, however, has made them valuable as places of exercise and recreation. This value has been clearly stated by Mr J. S. Mill (*Dissertations and Discussions*, vol. ii. p. 213): 'We must needs think, also, that there is something out of joint, when so much is said of the value of refining and humanising tastes to the labouring-people—when it is proposed to plant parks and lay out gardens for them, that they may enjoy more freely nature's gift alike to rich and poor, of sun, sky, and vegetation; and along with this a counter-progress is constantly going on of stopping up paths and enclosing commons. Is not this another case of giving with one hand and taking back more largely with the other? We look with the utmost jealousy upon any further enclosure of commons. In the greater part of this island, exclusive of the mountain and moor districts, there certainly is not more land remaining in a state of natural wildness than is desirable. Those who would make England resemble many parts of the Continent, where every foot of soil is hemmed in by fences, and covered over with the traces of human labour, should remember that where this is done, it is done for the use and benefit, not of the rich, but of the poor; and that in the countries where there remain no commons, the rich have no parks. The common is the peasant's park. Every argument for ploughing it up to raise more produce applies *a fortiori* to the park, which is generally far more fertile. The effect of either, when done in the manner proposed, is only to make the poor more numerous, not better off. But what ought to be said when, as so often happens, the common is taken from the poor, that the whole or great part of it may be added to the enclosed pleasure-domain of the rich? Is the miserable compensation, and though miserable not always granted, of a small scrap of the land to each of the cottagers who had a goose on the common, any equivalent to the poor generally, to the lovers of nature, or to future generations, for this legalised spoliation?'

Acting upon the principles expressed in this extract, the legislature in the 19th century has regulated enclosures with reference to the enjoyment of the general public, as well as to the rights of the lord of the manor and of the commoners. Restraints have been placed on the enclosure of commons in or near towns, and provision has been made for laying them out and maintaining them as places of recreation. Near London especially, many commons have thus been secured to the public. See Miss Octavia Hill, *Our Common Land* (1878); Elton,

The Law of Commons; Scrutton, *Commons and Common Fields* (1887); and works by Chambers, Cooke, Hall, and Williams.

In the United States the term 'common' is used in two senses. In one sense it signifies the common or general fields set apart as pasture-land at the foundation of towns or villages. The idea of such common fields may have been suggested by those of England, although the feudal lord of the manor was not retained by the settlers in America. Common fields also existed in the villages of French and Spanish settlers. The title to these lands was confirmed to the inhabitants by act of congress. Unappropriated lands in Virginia have similarly been confirmed as common lands by statute, and the constitution of Illinois sets apart certain lands as commons. Unless the statute expressly forbids, commons in this sense may be divided at the instance of individuals interested, if they think fit to take legal proceedings for that purpose. In the other sense, the term 'common' is applied to a public park which may belong to the municipality or to the nation—e.g. the Yellowstone Park—respecting which no individual or individuals can claim a division. Such parks are under the direct control of the authorities. As applied to a school, the epithet 'common' means public, supported by taxation, and open to all children of a certain age. It has no reference to the studies of the school.

Common Sense. THE PHILOSOPHY OF. There are certain beliefs that have been current among men in all ages, which by some philosophers have been declared to be groundless illusions. Of these, the most remarkable instance is the belief in an external, material world, independent of any mind to perceive it. Berkeley's doctrine (see BERKELEY) seemed to his contemporaries to contradict this belief, and affirm that there is no such thing as a material world; and Hume, carrying the same principles to their full length, disintegrated the world of spirits, and left nothing in nature but isolated ideas and impressions.

A dead-lock in philosophy was the result of these doctrines of Berkeley and Hume; and the solution offered by Reid consisted in setting up common sense as an arbiter from which there could be no appeal—that is to say, the universally admitted impressions of mankind were to be taken as corresponding to the fact of things without any further scrutiny. It is only the same view otherwise expressed, when it is declared by other philosophers that the deliverance of consciousness must be presumed true. According to Sir W. Hamilton, in the most elaborate vindication of the common-sense philosophy that has ever been produced (in his edition of Reid's works), consciousness assures us that, in perception, we are immediately cognisant of an external and extended *non-ego* (not-self); and that the testimony of consciousness must be viewed as entitled to prompt and unconditional assent.

The conclusiveness of this reasoning is disputed by many, who say that it is an abnegation of the tasks of philosophy, and may establish mere prejudices as dictates of consciousness. Consciousness (q.v.) is a very wide word, comprising indeed everything that we call mind. Suppose, it is argued, we were to maintain that the veracity of each one's memory was beyond all question or dispute, it would be apparent at once how the case really stands. But there must be a standard truth. Experience is the criterion how far the memory is to be trusted; and possibly the same may be true of the larger fact named consciousness. See PHILOSOPHY, PSYCHOLOGY.

The truths of common sense, assumed to be those of consciousness, are such as these: the

laws of Identity, Contradiction, and Excluded Middle; the axioms of Mathematics; the law of Causality (see CAUSE); the doctrine of an innate moral sense (see ETHICS); the doctrine of man's Moral Liberty (see FREE-WILL); the existence of an external world independent of every perceiving mind. Some of these truths, which however by no means stand all on the same footing, are termed Intuitions, Intuitive Cognitions, Instincts, Feelings, Beliefs, Principles, Ultimate or Primordial Elements, Truths *a priori*. Kant's mission was to investigate the origin of such of those truths as might be accounted *a priori*; see KANT, A PRIORI. The philosophy of common sense, as promulgated by Reid, bore reference especially to the denial by Berkeley of the received view of the material world; see PERCEPTION.

Commonly. See COMMONS AND ENCLOSURES.

Commonwealth (practically, a translation of Lat. *respublica*, 'republic') is used in a special sense for the form of government established in England after the execution of Charles I. in January 1649. Usually the Commonwealth is held to extend till the Restoration in 1660; and in the *Calendar of State Papers* this is the usage of the word. But the Commonwealth is sometimes limited to the period 1649-53, ending with the establishment of Cromwell's Protectorate. See CROMWELL, ENGLAND. Several states of the American Union (as Massachusetts, Pennsylvania, Virginia) are officially called commonwealths.

Commune is the unit or lowest division in the administration of France, corresponding in the rural districts to the English parish or township, and in towns to the English municipality. In France there are about 36,000 communes, with a considerable measure of self-government, with the power of holding property, &c. Each commune has a council elected by universal suffrage, and the council is presided over by a *maire* and one or more *adjoints* or assistants. In the larger communes the *maire* is selected by the central government out of the members of the council; in others he is appointed by the prefect of the department. The central government through its officials exercises generally a very large control over the affairs of the commune. For the Russian commune, see MIR, and RUSSIA.

The rising of the commune of Paris in 1871 should not be confounded with Communism (q.v.). It was a revolutionary assertion of the autonomy of Paris, that is, of the right of self-government through its commune or municipality. The theory of the rising was that every commune should have a real autonomy, the central government being merely a federation of communes. The movement was based on discontent at Paris, where the people found themselves in possession of arms after the siege by the Germans. The rising began on the 18th March 1871, and was only suppressed ten weeks later after long and bloody fighting between the forces of the commune and a large army of the central government; 6500 Communists having fallen during 20-30th May, and 38,578 been taken prisoners. See FRANCE; and see Lissagaray's *History of the Commune of 1871* (trans. by E. M. Aveling, 1886).

Communion signifies, in ecclesiastical language, that relation, involving mutual claims and duties, in which those stand who are united by uniformity of belief in one religious body or church. To exclude from this relation and its involved rights is to *excommunicate*. The most visible symbol of this relation being the partaking together of the Lord's Supper, that rite is often called the Communion. See LORD'S SUPPER, PRAYER-BOOK, LITURGY; and for Communion Table, see ALTAR.

Communism is a system of society in which common property is the recognised form. In later times it is an attempt to prevent or remedy the evils arising out of the inequalities of private property by holding property in common. But in primitive societies, in the hunting and pastoral stages of civilisation, communism was universal. It was only when the transition was made to a settled life and to agriculture that private ownership in land began to appear, and even then it was slowly introduced. Long after the private use of land had been established, the common ownership of it by the tribe or clan was still recognised and enforced, and the arable land of the community was subject to periodical redistribution with the view to cultivation. Survivals of this system still exist in various countries of the world, notably in Russia under the Mir.

In the ancient world a partial communism prevailed in Crete and Sparta. During the decline of Greece more systematic speculations and experiments in communism appeared. The most eminent example of the former was the republic of Plato, in which a community of goods and also of wives was taught, as the form of society among the ruling and military class. These were to be supported by the industrial classes, whose form of life is not indicated. In Palestine, about the Christian era, the Essenes were a society of recluses with celibacy and the community of goods.

A most remarkable instance of community of goods is that of the early Christians at Jerusalem, recorded in Acts, iv. 32. Under the influence of Christianity the rigorous and often merciless ideas and rights of private property developed in the ancient world, especially among the Romans, were greatly modified. Denunciations of wealth tending to communism are not infrequent in the church fathers. Not to mention the corporate property of the church itself, which in medieval times embraced about one-third of the land in the countries where it was established, many of the monastic institutions were based on the community of goods. During the middle ages, sects holding the community both of goods and women appeared, like the sect of the Giovannali in Corsica.

At times of social and spiritual change or fermentation communistic ideas usually grow up with special vigour. Such was the case at the Reformation, when the anabaptists Münster and Bockholt set up communism in Germany, and similar notions had a wide diffusion in other countries (see ANABAPTISTS). The most eminent literary form of it, combined with the noblest humanitarian ideals and practical suggestions for reform, which even yet have not been realised, was the Utopia of Sir Thomas More (1516). In that great work, besides the institution of common property, we have the most advanced views on toleration, universal education, a mild criminal code, sanitation, and a working-day of six hours. Campanella's *Civitas Solis* (1623) has a similar community of goods under the despotic rule of the wise men, with a working-day of four hours.

At the discovery of America the Spanish conquerors found a system of agricultural communism under a central despotism both in Mexico and Peru. Like the partial communism of Crete and Sparta it may have been a survival or continuation of the primitive communism. In the earliest English settlements in America, both Virginia and New England, a system of common property was attempted, but soon abandoned. During the fermentation which preceded and accompanied the French Revolution communistic ideas again emerged in the writings of Morelly and Mably. They are also found vaguely expressed in the works of Rousseau, and through him they to some

degree affected the principles of Robespierre and St Just; but the general tendency of the Revolution was to consolidate individual rights and private property. The conspiracy of Babeuf was intended to establish a systematic communism by revolution.

Socialism is a vague phenomenon which must not be identified with communism. Yet the movement is largely coloured with communistic conceptions, and in some of its schools a thoroughgoing communism is taught with lax notions as to the relation of the sexes. In the anarchist, as also in the Marx school to a considerable degree, socialism takes the form of a systematic community of property, associated with vague theories of the emancipation of women (see SOCIALISM). Different both from socialism and this aggressive communism are the communistic societies still existing in the United States. The latter are simply quiet efforts to realise for their members a happier state of things by community of property, but without a revolutionary propaganda and remote from the main current of modern social development. See BROOK FARM, PERFECTIONISTS, SHAKERS; Nordhoff's *Communistic Societies of the United States* (1875); and for the rising of the so-called Communists at Paris in 1871, which was a political and not an economical movement, see COMMUNE.

Commutation. See TITHES, PENSIONS.

Commutator, an apparatus attached to many electric machines for reversing the currents. See ELECTRICITY.

Comnenus, the name of a family, originally Italian, of which many members occupied the throne of the Byzantine empire from 1057 to 1204, and that of Trebizond from 1204 to 1461. See BYZANTINE EMPIRE, TREBIZOND, ALEXIUS, ISAAC. —ANNA COMNENA (q.v.), who lived in the first half of the 12th century, was a high literary as well as historical celebrity. —DAVID COMNENUS, the last representative of the imperial race in Trebizond, was executed at Adrianople in 1462, with all his family, by command of Mohammed II. The attempt to trace the descent of the Bonaparte family from a branch of the Comneni settled in Corsica is not supported by valid evidence.

Como, a city of Lombardy, Northern Italy, beautifully situated at the south-west extremity of the Lake of Como, 30 miles N. of Milan by rail. It lies in a valley, surrounded by hills, clad with luxuriant gardens, olive plantations, and orange groves, with here and there an old ruin cropping out. The city is surrounded by old walls flanked with towers, the gateways by which the walls are pierced being fine specimens of medieval military architecture. Among the principal buildings of Como are the cathedral (1396-1732), and the town-hall, built of marble, dating from the beginning of the 13th century. The chief articles of manufacture are silk, satin, gloves, and soap. By means of its port, Como carries on extensive trade in the produce of the district with Switzerland. Pop. with suburbs (1881) 25,560. Como, the ancient *Comum*, was the birthplace of Cæcilius Statius, the two Plinys, of several popes, and of the physicist Volta. In 1107 it began to war with Milan, and in the course of twenty years was utterly destroyed by its antagonist. As an important headquarters of the Ghibelline party, it was rebuilt in 1158 by Frederick Barbarossa, and remained a republic for two centuries, when it fell into the hands of the Viscontis, its history since that time being bound up with that of Milan.

Como, LAKE OF (Ital. *Lago di Como*, or *Il Lario*, ancient *Larius Lacus*), a sheet of water, in Northern Italy, lying at the foot of the Bernine Alps. It is chiefly formed by the river Adda, which enters it at its north, and issues at its south-eastern

extremity. The total length of the lake from Como to Riva is about 30 miles. Fifteen miles from its northern extremity, the promontory of Bellaggio divides it into two branches, the shorter of which is called the Lago di Lecco. The greatest breadth of the lake is 2½ miles, but throughout the greatest part of its length it is much less. It is 663 feet above sea-level, has a mean depth of 870 feet, and is 1352 feet deep at the deepest part. The beauty of the surrounding scenery and the salubrity of the climate have made the Lake of Como the most celebrated and most resorted to in Italy, its shores being everywhere studded with noble villas. See Lund, *Como and the Italian Lakes* (1887).

Comorin, CAPE (*Kumart*), the most southerly extremity of the peninsula of India, being, in fact, a sandy accretion to the termination of the Western Ghats. The low headland is in the state of Travancore, and its lat. and long. are 8° 4' 20" N., and 77° 35' 35" E.

Comoro Isles, a group of four islands belonging to France, in the Mozambique Channel, between Africa and Madagascar. The islands, which are of volcanic origin, are mountainous, and have an extremely fertile soil, are called Angaziya or Great Comoro, Anjouan or Johanna, Mohilla, and Mayotta. Great Comoro is 35 miles long, and has a population of 35,000; its highest point is 8500 feet. Johanna, next in size, with 12,000 inhabitants, has a British consul and a British coaling station. Mohilla, the smallest, is 15 miles long, and has 6000 inhabitants. These became French in 1886. Mayotta or Mayotte, 21 miles long, and with a pop. (1885) of 10,049, has been a French possession since 1841. At the capital, Dzaoudi or Nzaondzi, are government buildings, a few hundred French soldiers, and numerous officials. The annual imports and exports of the island have each a value of over 2,000,000 francs. In all the islands the blood of the natives is partially Arab, partially Malagasy; the Sakalavas having occupied part of Mayotte after the conquest of Madagascar by the Hovas. See MADAGASCAR.

Company, although it may be applied to every kind of partnership, is generally used in connection with the law of joint-stock companies. These differ from the ordinary Partnership (q.v.) chiefly in the fact of the shares of the capital stock being transferable, generally apart from the consent of the remaining partners, although power is often reserved to object to a transferee; and also in the fact that full powers of management are devolved on directors and other officials to the exclusion, more or less complete, of the shareholders. An unincorporated joint-stock company at common law, such for instance as the famous Carron Iron Company, is really a partnership in many respects, its partners being liable without limit for the debts of the company. Under the Letters Patent Act, 1837, however, it may obtain several privileges of incorporation.

It is not lawful for more than ten persons to carry on a joint-stock banking company at common law, nor for more than twenty persons to carry on any other kind of joint-stock company at common law: all such concerns must register under the Companies Acts. Unincorporated companies may be made bankrupt and wound up in the ordinary way by sequestration, but it is also competent by a liquidation petition to apply to them the usual machinery for recovering the contributions due by members of registered companies, and adjusting the rights and liabilities of contributories *inter se*. Of course, the constitution of such common-law companies varies indefinitely with the provisions of the agreement under which they act. There is also in existence a large class

of companies created by royal charter, which have a legal corporate existence apart from their individual members, and a perpetual succession and a common seal. In such cases the charter defines, more or less clearly, the objects and the powers of the corporation and the mode of management, but the majority of members have within these limits considerable powers of framing bylaws. Where the charter is silent on the subject there is no direct liability of the members to the public at all, and their liability is limited to the unpaid balance of their shares. But the crown was empowered by statute to express in such charters that the liability of members is unlimited; and such until 1882 was the position of most of the large Scottish banks. The royal power to create corporations by charter was in certain cases delegated to burghs in Scotland, who exercised it by granting seals of cause. Of course, the validity of the provisions even of a royal charter may be questioned in a court of law.

Still another class of companies consists of those incorporated by act of parliament. Here no objection can be raised to the act of an all-powerful legislature. Such statutes, besides conferring the ordinary privileges of incorporation, generally give further parliamentary powers required for the particular undertaking—e.g. a right to levy tolls. All such particular statutes, which can be obtained only on giving the guarantees required by the practice of parliament in private bills, are all now subject to the general provisions of the Companies Clauses Acts of 1845, 1863, and 1869. These general acts deal not only with such matters as the issue of new capital, the creation of debenture stock, the change of name, but also with the general administration of the company, the powers of directors, the transference and forfeiture of shares, &c. Such statutory companies may also be placed in liquidation under the Companies Act of 1862.

The great mass of joint-stock companies, however, in this country owe their incorporation not to royal charter or statute, but to registration under the Limited Liability Acts, which began in 1855, but which are now all merged in the great statute of 1862, supplemented on various occasions down to 1880. As a general rule the provisions of the Act of 1862 apply, without fresh registration, to the companies formed and registered prior to that date. The new procedure is that any seven people, by subscribing a memorandum of association which states the name, place of business, and general objects, and delivering it to the registrar (there is a separate registrar for England, Scotland, and Ireland), may obtain a certificate of incorporation with or without limited liability. The great majority of these companies have been limited by shares—viz. the shareholders are liable only for the amount uncalled upon their shares. But cases of unlimited liability are not uncommon, and both banks and insurance companies have frequently availed themselves of the facilities afforded by registration; in the case of banks, the liability remaining unlimited as regards the note issue, while the liability of shareholders for other obligations of the bank is restricted in the usual way. An insurance company requires to make a deposit of £20,000 before registration. It is sufficient if each of the seven subscribers of the memorandum of association subscribes for oneshare. Companies not formed for commercial profit may be registered by license of the Board of Trade. After the memorandum come the articles of association, which in most cases are, slightly modified, one of the sets of model regulations known as Schedule A and B of the statute. The general effect of registration is to make the applicants and

other members a corporate body with perpetual succession, a common seal, power to hold lands without intervention of trustees, and a liability of members for the time to pay calls on the shares, and a liability of all members, past and present, to contribute the amount of the uncalled capital in the event of a liquidation, excluding such members as have been a year out of the concern before the winding up commences. Past members only contribute if present members cannot make up the deficiency. Hence the lists A and B of contributories so unpleasantly known in the mercantile world. Contributories cannot 'set off' or deduct from their liability debts due to them by the company. But the constitution, so defined by the memorandum and articles of association, is elastic. By special resolution of the shareholders—i.e. a resolution passed by three-fourths and afterwards confirmed, which is also registered—capital may be increased, the amount of shares altered, the liability of directors made unlimited. With the consent of the Board of Trade, the company may even change its name.

It is common to reserve to the directors power to object to a transferee of shares, but where this is not done, the directors are powerless to prevent the common practice of transferring shares to persons of no means just before a liquidation arrives, at least where such transfer is out and out. After liquidation no change can be made on the register of shareholders, which decides the liabilities of parties. Mistaken entries, however, may be rectified by petition to the court, even after liquidation, but it is then too late to raise an action to set aside a contract to take shares on the ground of fraud or misrepresentation. The liquidation of the City of Glasgow Bank (1878-82) called attention to the fact that in Scotland, differing in this respect from England, notice of trusts was taken in the registers of companies, but this did not prevent the trustees and executors who were so entered from being held personally liable for the full amount of the calls made. The necessity of keeping a register of mortgages is a useful provision, and every shareholder is entitled to obtain copies of the annual accounts and of any special resolutions passed. General meetings must be held at least once a year. The Board of Trade have power to order a systematic inspection of the books and accounts of a company, if they are asked to do so by one-fifth of the shareholders. The strongest security reserved to the management of a company for payment of calls is the stringent power of forfeiture which is often exercised with unfairness and severity.

Upon the whole the statute of 1862 has been beneficial in the development of trade; but it has also produced a great mass of dishonest speculation, with which the common-law doctrines of fraud and misrepresentation have not been adequate to deal. The law will shortly be amended so as to take further securities for the substantial character of business and for the punishment of dishonesty. For further information on this subject, see DIRECTORS, and LIQUIDATION. Also see CORPORATION, GUILD, LIVERY, and RAILWAYS.

Company, in Military Organisation, is that part of a Battalion (q.v.) which constitutes a captain's command. In the British service there are 8 companies in an infantry battalion on the war establishment, each consisting of 3 officers—Captain (q.v.), lieutenant, and sub-lieutenant—5 sergeants, 2 drummers and buglers, 5 corporals, 108 privates, and 1 driver with 2 horses for the company general service wagon. The men of the Army Service Corps are also grouped in similar companies (see COMMISSARIAT). The company is both a tactical and administrative unit, and is divided into two subdivisions of two sections each.

Each company has its own arm and accoutrement chests, and keeps its own books.

In the Engineers the field company is commanded by a major, with a captain and 4 lieutenants under him, and a surgeon, all mounted. It also has 2 sergeants, 1 artificer, 1 trumpeter, and 26 drivers, who are mounted, and 154 dismounted non-commissioned officers and men. In a cavalry regiment a captain's command is a Troop (q.v.); but the corresponding artillery unit is a Battery (q.v.). In the United States service an infantry battalion consists of 2 or more companies, each officered by a captain, a first and a second lieutenant, 5 sergeants, and 4 corporals. On a war footing a full company of infantry consists of 101 officers and men; in time of peace of 3 commissioned officers and 54 men. In the German army a company comprises 249 combatants and 3 non-combatants, under a captain, who is a mounted officer, and 3 subalterns. There are 4 such companies in each battalion. The French, Russian, Austrian, and Italian companies are similar in strength to the German. See also BEARER COMPANY.

Company, of a ship, is considered to include the whole of the persons engaged on board, and paid for specific duties—exclusive, therefore, of troops and passengers, but including naval officers as well as crew. See CREW.

Comparative Anatomy, as distinguished from special anatomy (see ANATOMY), is the science which examines and compares the structure of two or more different kinds of animal, so as to discover their points of resemblance and unlikeness; and as such it is a most important department of the science of Biology (q.v.; see also CUVIER). In this work the articles in the various groups of animals (see BIRD, MAMMALS, REPTILES, &c.) deal with the resembling and contrasted features of these groups. 'Comparative' is used in an analogous sense in connection with philology and physiology.

Comparesetti, DOMENICO, philologist, was born 27th June 1835 at Rome. He studied the natural sciences and mathematics, next held a post in a library, and in 1859 was appointed to the chair of Greek in the university of Pisa, which he exchanged a few years later for the same chair in the Instituto di Studi Superiori at Florence. His studies bore fruit in frequent articles in the learned journals, and in a series of learned works, among them one on Greek dialects in South Italy (1866), on Virgil the Magician (1872), and on Homer and Pindar (1881). With D'Ancona he edited the invaluable *Canti et Racconti del Popolo Italiano* (1869 et seq.). To English folklorists his name is well known from his learned *Researches concerning the Book of Sindibad* (Folklore Society, 1882).

Compartment, a term in use in the Heraldry of Scotland, applied generally to the panel or other ornamental work placed below a shield on which the supporters stand, with which is sometimes intertwined the escrol in which the motto, or a second motto, is placed. Great latitude is allowed as to its form.

Compass, MARINER'S, is a magnetic instrument used by mariners to indicate the direction of the ship with respect to the magnetic north and south line, or, in other words, to give the azimuth of the ship with respect to the magnetic meridian. That the mariner may know his direction with respect to the geographical meridian, he must know the angle between the magnetic and geographical meridians (see DECLINATION), and as this angle is different in different years and at different places on the surface of the globe, the mariner must be able at any time to determine his position, when his charts will give him the necessary data to supplement his compass reading.

The directive property of the magnet seems to have been unknown in Europe till the 12th century. It appears, however, on very good authority that it was known in China and throughout the East generally at a very remote period. The Chinese annals assign its discovery to the year 2634 B.C., when they say an instrument for indicating the south was constructed by the Emperor Ho-ang-ti. The earliest reference to the making of magnets is in a Chinese dictionary of 121 A.D., where lodestone is defined as 'a stone with which an attraction can be given to the needle'; but this property of the lodestone could not fail to have been observed at a very much earlier time. At first the Chinese would appear to have used the compass exclusively for guidance in travelling by land, and we hear of their using it by sea only somewhere about 300 A.D. According to one account, a knowledge of the compass was brought to Europe by Marco Polo on his return from his travels in Cathay; but as against this, the late Mr William Chappell, in a letter to *Nature* (June 15, 1876), produced evidence to show that we owe the appearance of the compass in Europe in the 12th century to independent discovery, and not to importation from China.

The ordinary mariner's compass is made up as follows: The needle is a magnetised strip of steel, or in the better compasses a number of thin strips magnetised separately and then bound together. This is balanced so as to swing horizontally on a fine pivot. Fastened to the upper surface of the needle and swinging with it is a circular card marked with the thirty-two 'points,' and having the point marked N immediately over the end of the needle that is attracted to the north. The pivot on which the needle swings stands up from the bottom of a copper bowl, which has a glass covering to protect the contents from wind and weather. The compass-bowl is made of copper (a good conductor of electricity) in order to damp the vibrations of the needle. For the needle in moving induces currents of electricity in the

pass-bowl is sometimes filled with spirit, but the additional friction of the liquid interferes with the sensitiveness of the needle. The bowl is supported in Gimbals (q.v.) so as to remain horizontal in all positions of the ship. The whole arrangement is placed in the binnacle, situated when possible in the fore and aft line, and having provision for the placing of lamps to illuminate the compass-card by night.

The compass-card is represented in fig. 1. The four cardinal directions or 'points' are marked N. E. S. W., and there is a convenient notation for intermediate points. Thus the point midway be-

Fig. 2.

tween N. and E. is called NE., that again between N. and NE. is called NNE. (read north-north-east), and so on. The remaining sixteen points, such as NôE. (read north by east), are named on a plan which will be readily made out by an examination of the figure. These thirty-two points are often further subdivided into halves, quarters, and even eighths, and then we have $N\frac{1}{4}E.$, and so on. When the ship lies in the magnetic meridian, and points to the north, the N. point on the card is directed towards a black line, called the lubber's line, marked on the inside of the compass-bowl. Boxing the compass means reading off from memory the thirty-two points in order going round either way.

Modified forms of the compass are in use on land by surveyors and miners, and need not be further alluded to here.

By way of summarising the qualifications of a good compass, we shall describe the best compass in use—Sir William Thomson's, patented in 1876: A thin aluminium ring (fig. 2) is connected by silk threads with an aluminium boss, which rests on an aluminium cup having a centre piece of sapphire poised on an iridium point (fig. 3). Instead of a single needle there are eight thin strips of steel fastened to the silk threads as shown in the figure. The thin paper rim bearing the points is divided at intervals so that the contractions and expansions due to change of temperature may not produce warping of the aluminium. The whole arrangement weighs only 200 grains or so, and thus there is very little tendency to flatten the point of the

Fig. 1.

copper bowl, the electro-magnetic forces of which tend (according to Lenz's Law) to oppose the motion producing them. For the same purpose also the com-

supporting needle. Hence the 'friction error' can be made very small—in fact, if it is found that a card can be made to rest even half a degree out of the magnetic meridian, the supporting point is rejected for a sharper one.

Fig. 3.

The weight, such as it is, being mostly in the rim, the period of vibration of the card is long (40 seconds, or so), which makes the card very steady. The bowl is saved from violent oscillation by having in the bottom a quantity of castor-oil. The gimbals are supported on knife edges, and their being made of brass wire-rope dispenses with the not very durable india-rubber pads otherwise used. A simple device prevents the card from jumping off the pivot when heavy guns are fired—a matter of some importance in an engagement. The binnacle has complete provision

for stowing away the magnets, soft iron bars, and spheres used to counteract the magnetism of the iron of the ship.

Along with Thomson's compass is supplied a piece of apparatus for converting it into an azimuth compass, which is a compass for finding the angle subtended at the observer's eye by the projections of two objects on the horizontal plane.

For the earth's action on a magnetised needle suspended free to move horizontally and vertically, see the articles **MAGNETISM**, **DECLINATION**.

The great difficulty connected with the use of the compass arises from the disturbing influence of the ship's magnetism, of which part is considered permanent, and part—due to the soft iron—is temporary, and varies with the position of the ship. Various methods are in use to regulate this difficulty, which in iron vessels is sometimes so great as to make an ordinary compass almost useless. The principal are (1) counteracting the permanent induced magnetism by properly placed permanent bar magnets; and (2) supplying about the compass soft iron masses in such a way that, however the ship turns, the transient induced magnetism on the left of the compass shall be exactly equivalent to that on the right. Many of the best ships carry a standard compass placed as far as possible from the iron of the ship, especially from vertical masses like iron masts and funnels. When it is mentioned that an error of one point ($11\frac{1}{4}^\circ$) in steering means an error of about one mile in five, the necessity for the various precautions will be readily recognised. For details on this subject, see the *Admiralty Manual on the Deviations of the Compass*, and the references there given.

Compasses, instruments for transferring and marking off distances, or for drawing circles, &c. The common compasses are simply two rods or 'legs' joined together at one end by a pivot-joint, and pointed at the other; when used for drawing circles, the lower part of one of the legs is replaced by a pen or pencil. Spring dividers are much in use by workmen; in these, the legs are united by a strong steel spring, the action of which is to stretch them open; but half-way down, a screw passing between the legs, regulates by means of a nut, the degree of opening. The value of these depends upon the permanency with which they retain any degree of opening given to them, pivot compasses being liable to slip. A more delicate variety of the spring dividers is

also made for use in mechanical and architectural drawing.

Beam Compasses consist of points sliding on a long bar, to which they may be clamped at any distance from each other. They are used for greater openings than pivot compasses can safely span, and, when delicately made, for more accurate dividing. See **GRADUATION**.

Proportional Compasses have a point at each end of each leg and the pivot between, thus forming a double pair of compasses opposite to each other, end to end. The pivot is a clamping screw moving in an elongated slit in the legs, by means of which any proportion between the ends may be attained. They are usually provided with scales of proportions for lines, solids, cubes, and circles. They are very useful in making reduced or enlarged copies of drawings, especially mechanical drawings.

Triangular Compasses have three legs, so that the points of a triangle may be all transferred at once. For Calliper Compasses, see **CALLIPERS**.

Compensation is used in both English and Scottish law to denote the claim which arises to the owner or occupier of land which is taken for the purposes of a public undertaking under statutory powers, or which is injuriously affected by the execution of public works. The question is generally referred to arbitration, under the Lands Clauses Act, and the award is final as to the amount of damage. The claim includes such matters as loss of profits from shop, interference with access and amenity, nuisance from smoke, &c. Formerly, fifty per cent. used to be added for compulsory purchase, but latterly awards have been more moderate. Compensation is also the name given in recent statutes to the right of an outgoing tenant in respect of certain classes of unexhausted improvements which are scheduled to the acts. See **AGRICULTURAL HOLDINGS ACT**. The word is loosely applied to any claim of damages arising in respect of injury. Thus in event of legislation interfering with the business of the publicans (in the way of limitation or prohibition), it is strongly affirmed by some, and as strongly denied by others, that the publicans are entitled to compensation. In Scots law its proper meaning is that mutual creditors and debtors may set off one debt against another. This applies, as it did in the civil law, to most pecuniary obligations, but in order that one debt may extinguish another, so as to stop interest, &c., compensation must be pleaded. Even where an unliquidated claim of damages is opposed to an ascertained debt, time will be given to constitute, if the claims arise under the same contract.

Compensation of Errors, in Physics, a method of neutralising errors which cannot be avoided, by introducing others into the experiment or observation, of an opposite nature, and equal in amount. The compensation pendulum illustrates the principle. See **PENDULUM**.

Competition (Lat., 'a seeking together') has been well defined by Dr Johnson as 'the act of endeavouring to gain what another endeavours to gain at the same time.' In political economy it is simply the form taken by the struggle for existence as applied to industry. Formerly, prices and generally the economic relations of men to each other were regulated by custom or authority. The growth of freedom has now brought it about that these relations are determined by individual effort. The general rule is that each man must be responsible for his own economic well-being. The workman brings his labour to the market and gets what he can for it. The capitalist engages labour on the terms most favourable to himself, and sells his produce at such price as it can bring. The

owner of land generally takes the highest rent he can obtain. In short, the industrial world is a world of conflicting or competing interests.

As we have said, this system of competition is an outcome of modern freedom, and the rise of it may be historically traced. In medieval times the relations of men were fixed by custom or authority. But the restraints of custom and authority were felt to be vexatious, oppressive, and injurious, and in the various spheres of human activity, in religion, politics, and economics, the free individuality of men sought and found wider room to develop itself. This great movement began with the revival of learning, the discovery of America, and the Protestant Reformation, and has been continued through the revolutions of the 17th, 18th, and 19th centuries. In the industrial sphere it means that whereas in former times a man's calling, place of residence, and the remuneration of his industry were fixed for him, he is now at liberty to decide them for himself as best he can. Each man is free to do the best he can for himself, but as he finds numerous individuals who exercise the same freedom within a limited field, there arises the prevailing system of competition.

No one conversant with the facts will deny that the system of free competition has been attended with enormous progress, and that it has acted as a powerful stimulus to human energy and the spirit of improvement. But the development of the system has brought with it most important limitations, some of which may be noted. While such a system must always be limited by law and justice, and the necessities of political union, legislation has been obliged to provide special safeguards against the evils of competition, notably in the English Factory Acts. The English trades-unions are an attempt to regulate competition in the interest of labour. Employers' combinations have a like object in the interest of the capitalist. In America especially the development of 'trusts' tends to make competition a dead letter. These trusts are combinations of capitalists with a view to regulating prices. The protective system of countries like France, Germany, and the United States is intended to maintain native industries against British competition. Lately France and Germany have imposed duties on cereals in order to protect their agriculture against American competition. It should be noted also that even yet custom is largely influential in many spheres, and that not a few of the evils of competition are mitigated by the kindly feeling which prevails in all the relations of life. Employers do not generally bring wages down to the lowest level attainable by competition. Thus in actual experience the competitive system is modified by a great variety of influences. On the other hand, the 'sweating system,' by which starvation wages are given for long hours of hard work, is rendered possible by the keen competition of many, otherwise unemployed, for such unremunerative labour.

Competition for situations in the public service is very different from the system above described. Competition as applied to the public service is regulated by the state. The salaries in the various grades, and the conditions of employment, are fixed by authority. The chief material stimulus is the hope of promotion. See CIVIL SERVICE. For the advantages and disadvantages of competitive examinations in education, see EDUCATION; also the *Nineteenth Century*, the *Universal Review*, &c., for 1888.

Compiègne, a quiet and old-fashioned but picturesque town in the French department of Oise, on the river Oise, a little below its junction with the Aisne, 52 miles NNE. of Paris by rail. Of its churches three deserve notice, St Germain

(15th century), St Antoine (12th century), and St Jacques (13th century). The hôtel-de-ville is a late Gothic edifice with a fine central belfry. But the chief pride of Compiègne is its palace, built anew by Louis XV., and splendidly fitted up by Napoleon, who often occupied it. Its façade towards the forest is 624 feet long. From the gardens an arbour walk, 1600 yards long, leads towards the beautiful forest of Compiègne, which was a favourite hunting-ground of many of the kings of France. It extends to over 30,000 acres, and contains some fine oak timber. The inhabitants of Compiègne manufacture canvas, cordage, and sugar. Pop. (1872) 11,859; (1886) 13,857. Compiègne is mentioned in the times of Clovis under the name of *Compendium*. It was at the siege of this town, in 1430, that the Maid of Orleans was captured; and here, in 1810, Napoleon first met Maria Louisa of Austria, on occasion of their marriage.

Complement of an angle is what it lacks to make up 90°; of an arc, to make up a quadrant; and hence, in Astronomy, the complement of a star is its zenith-distance. In Music, two intervals, which together make up an octave, are called complementary (see INVERSION). In Arithmetic, if any number is subtracted from the next higher power of ten, the result is its complement. Thus 7 and 3 are complementary; so are 63 and 37; 881 and 119; and 1·4384386 is the complement to 8·5615614. In Chromatics, red is the complement of green, orange of blue, and yellow of violet.

Complutensian Bible. See ALCALA and XIMENES.

Compony, or GOBONY. See BORDURE.

Compositæ. This is the richest of all natural orders in species, these numbering about 10,000; it is also the most widely distributed through all regions of the globe, although most abundant in temperate and subtropical climates; and, furthermore, the richest in individuals, it having been reckoned that about every tenth plant on the earth's surface is a composite. The rationale of this may be broadly seen (at least if we grant an individual constitution and structure especially well adapted to both vegetation and reproduction), for we can see that the consequent great number of healthy individuals must be associated with active local competition and survival of the fittest, and with distribution of these over a wide area; while this again is at least one condition of considerable differentiation of varieties, and so ultimately of species.

While popularly a daisy or dandelion is regarded as a simple flower, the roughest examination suffices to analyse this into an orderly assemblage, technically a *capitulum* of small but distinct florets; hence the beginner is apt, without more ado, to refer all similar aggregates, say a head of Scabious (*Dipsacaceæ*) or Scapink (*Plumbaginaceæ*) to the Compositæ. We find, however, such aggregates arising in all alliances, and naturally so; racemes, spikes, or umbels of flowers wholly distinct in structure may all be shortened down into heads or capitula, since reproductive development is tending everywhere to check vegetative growth. We are thus led to inquire of what forms are the composites to be regarded as the reduced members, and the evidence of comparative anatomy goes to prove their relationship to Campanulaceæ and their irregular forms the Lobeliaceæ; in a word, to view the yellow 'tubular' florets of our daisy as a head of tiny bells, while the white strap-shaped or 'ligulate' ones of its ray, like all those of a dandelion, resemble the flowers of lobelia.

In shortening down, or less figuratively, in arresting the inflorescence into a head, the bract of each separate flower remains in place; and in a *Zinnia*, or sunflower, we find each floret with its separate bract throughout the whole capitulum; in most cases, however, these disappear. Those of the outermost florets, however, together with the immediately lower leaves of the flower-axis (which bear no florets, and are thus in strictness not entitled to their common name of bracts) become usually crowded into an *involucre*. This subserves in bud the protective purposes of a calyx to the whole inflorescence at once, and thus the calyx of the separate florets becomes unnecessary. In its place we find at most a circle of fine downy hairs, which may be characteristically serrated or feathered, and which only reach full development and usefulness when the fruit has to be distributed. On account of its merely epidermic nature and late appearance, its calycine nature has been denied, and the term *pappus* substituted; the evolutionist need, however, feel little hesitation in regarding the pappus as simply representing the epidermic fringe of a reduced calyx, nor is verificatory evidence wanting. The stamens grow upon the united corolla and themselves unite by the anthers, thus forming a ring or rather pollen-bearing tube, up through which the style grows, all much as in bells. The style bears two stigmas, indicating an originally two-carpelled arrangement, but the ovary is one-celled, and contains only a single ascending ovule. The ovary hardens as a nutlet, which is commonly floated away upon the wind when ripe by help of its pappus; it may be anchored where it descends by its minute grappling-hooks or serrations. In this way it is conveyed to new soil, it may be at a great distance, an obvious advantage, alike to the species or the individual, when germination takes place.

The classification of so many closely related genera and species into larger groups is one of the most difficult problems of the systematist, and all attempts must as yet be admitted to be largely artificial. The method of Jussieu is to separate (1) those in which the florets are all tubular, as in the thistles (even though the outer be enlarged as in corn-flowers—see CENTAURY), as Cynarocephalæ; (2) those in which, while the inner florets are tubular, the outer are ligulate as in daisy, sunflower, &c., as Corymbiferae, and (3) those in which all the florets are ligulate, as in dandelion or chicory, as Cichoraceæ. The more recent method of De Candolle is now more generally adopted: his distinctions are (1) Tubulifloræ, including those which have mainly tubular florets, although the ray be ligulate, thus abandoning the attempt to separate the first two divisions of Jussieu; (2) Ligulifloræ, with florets all ligulate, corresponding to Cichoraceæ; (3) Labiatifloræ, with florets all bi-labiate, a small South American group. But while this last group has unquestionable distinctness, the value of both preceding classifications in other respects is shown to be somewhat superficial by the familiar fact that in cultivation tubular florets tend to become ligulate (in inaccurate popular phrase, *double*). Thus we see the wild daisy, dahlia, chrysanthemum, &c., alike practically passing into the ligulate group on cultivation.

Although many composites are cultivated and useful plants, none attain the highest economic importance: yet the artichoke, and Jerusalem artichoke, salsafy, lettuce, endive, &c., are familiar inmates of the kitchen-garden, while chicory is extensively cultivated as a substitute for coffee, and even sometimes, as well as Jerusalem artichoke, for the purpose of feeding domestic animals. A very few, like safflower and saw-wort,

yield dyestuffs; from the seed of others—e.g. sunflower, a bland oil is expressed, while many are of time-honoured repute for their medicinal properties—e.g. chamomile, arnica, wormwood, elacampagne, &c. A still greater number—e.g. headed by dahlias and sunflowers, asters and chrysanthemums—are esteemed ornaments of our flower-gardens, particularly in the latter part of summer and in autumn. Being mostly herbs, or rarely shrubs, the order is quite unimportant as regards timber: the Siriehout (*Tarchonanthus camphoratus*), a small tree of the Cape of Good Hope, is, however, close-grained and beautiful.

For detailed information, see systematic works such as Luerssen, *Med. Pharm. Botanik*; Baillon, *Histoire des Plantes*; or Engler's *Pflanzen-familien*.

Composite Order. See COLUMN.

Composition. Under the title Composition and Resolution of Velocity and Forces, we deal with one of the fundamental problems in mechanics—viz. to compound two velocities (or forces) into a single velocity (or force) which shall be their equivalent. We shall consider it as applied to velocities in the first place.

If a point is moving with two independent velocities in any direction, it moves in some one definite direction with a definite speed. This single velocity (for the term includes the idea of direction as well as speed) is equivalent to the two component velocities, and is termed their *resultant*. A good example is afforded by a ball thrown up in a moving railway carriage; it partakes of the train's motion horizontally, while it also simultaneously moves vertically upwards.

When the two components are in the same straight line, their resultant is in all cases equal to their algebraic sum. In the case of velocities in different directions, the magnitude and direction of their resultant is obtained by the following theorem, known as the *Parallelogram of Velocities*: If a point A move with two velocities, represented in magnitude and direction by AP and AQ respectively, their resultant will be similarly represented by AR, the diagonal of the parallelogram of which AP and AQ are

conterminous sides. For, let the point move along AQ with velocity AQ, and let the page be in motion in the direction AP with velocity AP. After a unit of time has elapsed, the point will have moved from A to Q along AQ, but, owing to the motion of the page, the line AQ will have moved into the position PR, so that the point will really be at R; hence its motion has been in the direction AR, with a velocity whose magnitude is represented by AR.

Similarly, we may compound any number of velocities in one plane into a single resultant. In the case where three components are not coplanar, a corresponding theorem, the *Parallelepiped of Velocities*, is used to find the resultant.

The resolution of velocities is exactly the converse problem; for where a directed length such as AR can be made the diagonal of a parallelogram, then the conterminous sides are the components. Of course, in this manner, an infinite number of pairs of components can be obtained, each having the given velocity as their resultant. But the resolutions usually required are those in which the components are at right angles.

Since forces can be graphically represented in the same manner as velocities, all that has been said of velocities applies equally well to forces; and obvious changes in the terminology at once give

the means of compounding and resolving forces. See DYNAMICS, KINEMATICS, STATICS.

Composition, in Bankruptcy, a certain percentage which creditors agree to receive from a bankrupt in lieu of full payment of his debts, and the acceptance of which operates as a discharge to the bankrupt. See BANKRUPTCY.

Compos Mentis. See INSANITY.

Compostella. See SANTIAGO DE COMPOSTELLA.

Composts are a kind of Manure (q.v.), consisting of mixtures of substances adapted to the fertilisation of the soil, which being allowed to ferment, and undergo chemical changes for a considerable time in heaps, become more valuable than they were at first, or ever could have been if applied separately. Composts were formerly made of farm-yard manure, and earth or lime in addition. Road-scrappings, peat-moss, leaves, and clearings of ditches also formed materials for the purpose. By allowing these to lie for six months in heaps of from three to four feet in depth, food was prepared for plants. The mass was usually applied to the turnip-crop, and when artificial manures were unknown, considerable benefit arose from such dressings. The use of guano and other light manures has superseded in a great measure the necessity of this laborious process, and composts for the turnips or barley-crops are now little used. The wonderful effects that have resulted from the application of small doses of artificial manures have impressed farmers in general with the truth that the most energetic elements bear a small proportion in weight to the whole mass of farm-yard dung or composts, and that the mixing of manures in heaps with earth does not so much add to its virtues as to repay the labour expended in the process. More care is now rightly bestowed in preserving manure from washings by rain. Composts formed of leaves, ditch-scurings, road-scrappings, or any earthy substance containing a large percentage of vegetable matter, with the addition of lime, may still be used with benefit for pastures that are deteriorating, or where the soil is stiff. Indeed there should still be a compost-heap at every farm. Wherever tidy and careful management prevails, there is a good deal of road-scrappings, ditch-scurings, and other rubbish to be disposed of, and the compost-heap is a handy and useful receptacle for all such matter. The value of well-made compost for the top-dressing of pasture-land is greater than is generally understood or acknowledged, and it can be carted out and spread at odd times when there is a lull in the more urgent farm-work. Where moss prevails, lime should enter largely as a component. On the other hand, where the soil is of a strong and clayey nature, earthy substances containing vegetable matter in larger proportions should be used. Vegetable matter has the effect of imparting a softness to the surface that is particularly conducive to the free growth of pastures. Compost made of turf, leaves, earth, and bone-dust is used with great benefit by gardeners for vines and fruit-trees which are injured by too concentrated manures.

Compound (corruption of Portuguese *campenha*, 'yard or court') is the usual name in India for the inclosure in which a house stands, with its outhouses, yard, and garden.

Compound Animals. See COLONIAL ANIMALS.

Compounding of Felony, in England, is the offence of taking value for forbearing to prosecute a felony, and is punishable with fine and imprisonment. The offence is also known as agreement not to prosecute, and is equally committed

where the agreement is only to show favour to the person accused. It practically amounts to misprision of felony. Compounding of informations upon penal statutes, and compounding of misdemeanours, without order or consent of the court, are punishable in a lighter degree, and that whether any offence has been committed or not. But in misdemeanours affecting some private rights, the court will often permit the prosecutor to accept pecuniary amends, and withdraw the prosecution. Advertising a reward for stolen property, coupled with words implying that no questions will be asked, or that no prosecution will be instituted, or that a pawnbroker returning the property will be paid what he has advanced on it, is punishable by a fine of £50 each on the advertiser, publisher, and printer. And any one taking money or reward for restoring a stolen dog is liable to imprisonment for eighteen months.

Compound Interest. See INTEREST.

Compressed-air Bath, a strong chamber of riveted iron plates in which two or more persons can sit, and into which air is driven by a steam-engine to any required pressure, as notified by the attached barometers. The inflow of fresh air and the escape of the foul air are regulated by valves. Patients remain in the bath from one to three hours, and the pressure is generally increased to an atmosphere and a half. Another appliance for using either compressed or rarefied air consists of a mask tightly covering mouth and nose, and connected by a tube and suitable valves with some form of air-cistern in which the pressure can be varied as desired. By this appliance patients can either inspire compressed or rarefied air, or can breathe out into either of these. Practically only the first and fourth of these possible methods are used. Treatment by *Acrotherapeutics* has long been a favourite study, but the results have varied much, and have lacked exactness. The general effects of compressed air are to lessen the frequency of the movements of the chest, and of the heart or pulse beats, while allowing the absorption of more oxygen, and increasing the blood-tension. Rarefied air produces the opposite effects. Many diseased conditions therefore should benefit by this treatment, especially asthma, chronic bronchitis, and catarrh under compressed air, and emphysema by rarefied air; while in the treatment generally we have a useful system of lung gymnastics, which increase the power of the respiratory muscles and the vital capacity of the lungs.

Compressed-air Motors. One mode of employing air as a motive power has been described under AIR-ENGINE (q.v.). Another obvious way is to compress the air and then apply it in the manner of high-pressure steam. But the great loss of power, due principally to the dissipation of the heat which results from the high compression of the air, will always render the employment of such a motive power very wasteful. There are, however, many conditions under which the use of compressed air is convenient and advantageous. The air-gun, although more a toy than a useful weapon, is one of the oldest examples of a compressed-air motor. Partly by compression and partly by exhaustion of air, pneumatic tubes are worked in connection with central post-offices for the transmission of letters and messages to and from various districts in large cities. In boring in mines, and in blasting and tunnelling operations, compressed air is an exceedingly useful agent, the power being easily carried by tubes into confined areas where the air when liberated, after it performs its primary duty, is of great value for aiding the ventilation of the spaces (see BORING). In the application of automatic brakes to passenger trains,

compressed air has also been found to be the most convenient power (see BRAKE). Air compressed and stored in a reservoir under the vehicle has also been proposed as a motive power for tramway cars. In a different direction the agency of compressed air is important in the artificial production of cold for chilling-houses for meat-preservation on land, and for frozen-meat chambers for preserving fresh meat on board vessels (see REFRIGERATION).

Compression and Compressibility. When a body is subjected to the action of any force which causes it to occupy less volume, it is said to be compressed, and the diminution of volume is termed *compression*. The term compressibility is frequently used to signify that property of bodies whereby they yield to that particular form of stress known as pressure; but more strictly it is employed to denote the measure of this property as possessed by different substances. Under the same pressure it is obvious that the same volume of various substances will diminish by different amounts; and, to measure this change, the *compressibility* is defined to be the ratio of the amount of compression per unit volume to the compressing force applied. It thus may be determined by measuring the amount of compression of a known volume when under a certain pressure; dividing this by the product of the original volume and the pressure gives the average compressibility (per unit pressure) of the substance throughout the range of pressure employed. The unit of pressure generally used is *one atmosphere*, which is defined in this country as being the weight of a column of mercury, one square inch in section, 29·905 inches in height, at the temperature of 0° C., and weighed at sea-level in the latitude of London. Its actual value in pounds-weight per square inch is nearly 14·7; so that 152·3 atmospheres of pressure is equivalent to a pressure of one ton per square inch.

In gases the relation between pressure and volume is given by Boyle's Law (see GASES)—viz. the volume of a given mass of gas is inversely proportional to its pressure. From this it follows that the compressibility is inversely proportional to the pressure—i.e. the diminution of volume due to a given increment of pressure is correspondingly small as the pressure is great. The behaviour of a gas under pressure is closely related to the proximity of its temperature to the critical point (see CRITICAL TEMPERATURE); for if below this

temperature the gas can, and if above it, cannot be liquefied by pressure alone. It is only since 1877 that liquefaction has been effected in those gases formerly termed permanent.

From the first attempts to compress liquids it was concluded that they were incompressible, but Canton in 1762, by a comparatively simple experiment, showed that the compressibility of water though small is quite appreciable, and that it is less at higher than at lower temperatures. The measurement of the compressibility of liquids is usually made in a glass vessel (see fig.) termed a piezometer. A tube, ABCD, open at one end, D, is bent upon itself between C and D, widened at one end into a cylindrical bulb, AB, and at the other into a cistern, D. The liquid experimented on fills the bulb and stem to C, from which point to D, mercury fills the tube. On the surface of the mercury at C an index

floats. The instrument is placed in a larger and much stronger vessel containing water to which pressure (measured by an attached gauge) is applied. The contents of the piezometer being

thus compressed, the mercury column ascends in the stem, and when the pressure is relieved the index is left at that point to which the mercury rose under the highest pressure applied. The actual amount of compression, and the original volume, as well as the pressure, being known, the compressibility can be thereby calculated, a correction being finally added for the compression of the glass piezometer itself. From experiments made with such apparatus, the following conclusions (see *Report on some of the Physical Properties of Fresh Water and Sea-water*, by Professor P. G. Tait; *Challenger Expedition Commission Reports*, Physics and Chemistry, part iv.) seem now to be well established regarding the compressibility of liquids, more especially of water. The compressibility of water decreases as both the temperature and pressure are raised; under moderate pressures (e.g. one or two atmospheres) it has a point of minimum value about 60° C., while its actual value at 10° C. and at a pressure of one ton per square inch is very nearly $\frac{1}{10000}$. Sea-water is less compressible than fresh water; the ratio of the compressibility of the former to the latter being ·915. Solutions of common salt are less compressible as they are stronger; the compressibility falling off uniformly with increased strength. Both sea-water and salt solutions diminish in compressibility with temperature and pressure in the same manner as fresh water. It has also been proved that the maximum-density point of water is lowered by pressure; the actual amount of this lowering being 3·1 C. per ton—i.e. water under a pressure of one ton per sq. in. has its maximum density point at 0°·9, instead of at 4°, as under ordinary atmospheric pressure.

The compressibility of solids is generally very much smaller than that of either liquids or gases. It is best measured by noting the shortening of a rod or fibre of the material tested while subjected to hydrostatic pressure; the linear compressibility thus obtained is, to a sufficient degree of approximation, one-third the cubical compressibility. For glass it is ·00000265 per atmosphere.

Compulsion. The effect of compulsion on the validity of obligations and payments, and on criminal responsibility, is noticed under CONTRACT, CRIME, FORCE AND FEAR, and DURESS.

Compurgators were twelve persons whom Anglo-Saxon law permitted the accused to call in proof of his innocence, and who joined their oaths to his. They were persons taken from the neighbourhood, or otherwise known to the accused. It was rather in the character of witnesses than of jurymen that they acted, though the institution has been spoken of as the Anglo-Saxon jury; what they swore to was not so much their knowledge, as their belief. The number of compurgators varied with the rank of the parties and the nature of the accusation, but was usually twelve. The system of compurgators was adopted even in civil actions for debt. Compurgation, which was a custom common to most of the Teutonic races, fell into disuse after the conquest; but the ceremony of what was called canonical purgation of clerks-convict, was not abolished in England till the reign of Elizabeth. See JURY TRIAL.

Comrie, a pleasant and sheltered village of Perthshire, on the Earn, 7 miles W. of Crieff. It has often been visited by earthquakes, notably in the October of 1839 and January of 1876. These are apparently due to its geological position on the great line of fault between the Highlands and the Lowlands. Here George Gilfillan was born in 1813. The Free church was built in 1879-81, at a cost of over £10,000. Pop. 1038.

Comstock Lodge, a ledge of silver, to which Virginia City, Nevada, largely owes its prosperity. Discovered in 1859, the lode has since yielded at times over ten million dollars annually. The shaft is 2300 feet deep, but work is now confined to the upper levels, the workmen having been driven from the depths by the heat (120° F.) and by the steam generated through the action of the air on the sulphurous rock penetrated by the different levels.

Comte, AUGUSTE, the founder of Positivism (q.v.), was born 19th January 1798, at Montpellier, where his father was treasurer of taxes. At the Lycée of his native place he was distinguished equally for his aptitude for mathematics and his resistance to official authority, characteristics which did not desert him on his entering the École Polytechnique at Paris in his seventeenth year. Here he took the lead in a protest of the students against the manners of one of the tutors, and was expelled, after a residence of two years had obtained recognition of his abilities from the professors. A few months were spent with his parents, and then Comte returned to Paris, where for a time he made a scanty living by teaching mathematics. It would seem that, some years before, he had completely freed himself from the influence of all existing social and religious theories, and a reforming zeal was beginning to possess his mind, when in 1818 he came into contact with St Simon, by whom his inclination towards the reconstruction of thought and life was confirmed and strengthened. A definite relation was established between them, by which Comte remained for six years the disciple and collaborator of the older thinker; but there gradually became apparent a disagreement of aim and method, and the necessity felt by Comte of asserting the independence of his own conceptions led to a violent rupture. In 1825 Comte married, but the union proved unhappy, and after seventeen years of intermittent discord, ended in a separation. In the following year Comte began a course of lectures in exposition of his system of philosophy, which was attended by several eminent men of science, but the course was soon interrupted by an attack of insanity, which disabled the lecturer for a few months. His labours were afterwards resumed, and the six volumes of his *Philosophie Positive* was published at intervals between 1830 and 1842, during which period his livelihood was chiefly obtained from the offices of examiner and tutor in the École Polytechnique. After these positions were taken from him, owing to the prejudices of his colleagues, he resumed the private teaching of mathematics, but in his later years he was supported entirely by a 'subsidy' from his friends and admirers. In 1845 Comte became acquainted with Clothilde de Vaux, and until her death within a year afterwards, a close intimacy was maintained between them. On Comte's side it was a passionate attachment, the purity of which was happily preserved, and its influence is clearly shown in his later works, especially in the most important of these, the *Politique Positive*. Comte died in his sixtieth year on 5th September 1857. He was buried in the cemetery of Père-la-Chaise. A full account of his system will be found in the article POSITIVISM. His works are *Cours de Philosophie Positive* (6 vols. Paris, 1830-42; freely translated into English, and condensed by Harriet Martineau, 2 vols. 1853), *Traité Élémentaire de Géométrie Analytique* (1843), *Traité d'Astronomie Populaire* (1845), *Discours sur l'Ensemble du Positivisme* (1848), *Système de Politique Positive* (4 vols. 1851-54; Eng. trans. 1875 et seq., Longmans), and *Catéchisme Positiviste, ou Sommaire Exposition de la Religion Universelle* (1 vol. Paris, 1852). Comte's *Testament* was published with a good many of his letters in 1884.

Comus, in later antiquity, a divinity of festive mirth and joy, represented as a winged youth, sometimes drunk and languid as after a debauch, or slumbering in a standing posture with legs crossed. Comus thus became the representative deity of riotous merry-making, of tipsy dance and jollity, and as such figures in Milton's noble poetic tribute to chastity, the mask of *Comus*; though here the poet, as elsewhere, has devised his own mythology, and made him the child of Bacchus and of Circe, 'much like his father, but his mother more.'

Comyn, CUMMING, or CUMYN, a family which rose to great power and eminence in England and Scotland. It took its name from the town of Comines, near Lille, on the frontier between France and Belgium. While one branch remained there, and in 1445 gave birth to the historian Philippe de Comines (q.v.), another followed the banners of William of Normandy to the conquest of England. In 1069 the Conqueror sent Robert of Comines, or Comyn, whom he created Earl of Northumberland, with 700 horse to reduce the yet unsubdued provinces of the north. He seized Durham, but had not held it for 48 hours when the people suddenly rose against him, and he perished in the flames of the bishop's palace, leaving two infant sons. The younger, William, became Chancellor of Scotland about 1133, and nine years later all but possessed himself of the see of Durham. The chancellor's grandnephew, Richard, inherited the English possessions of his family, and acquired lands in Scotland. By his marriage with Hexilda, the granddaughter of Donald Bane, king of the Scots, he had a son William, who was Great Justiciary of Scotland, and about 1210 became Earl of Buchan by marrying Marjory, daughter and heiress of Fergus, the last Celtic Earl of Buchan. Their son, Alexander, Earl of Buchan, married Isabella or Elizabeth, second daughter of Roger de Quenci, Earl of Winchester, and with her acquired the high office of Constable of Scotland, with great estates in Galloway, Fife, and the Lothians. By a previous marriage with a wife whose name has not been ascertained, William Comyn was father of Richard—whose son John (Red John Comyn) became Lord of Badenoch—and of Walter, who by marriage became Earl of Menteith, and was one of the guardians or regents of Scotland during the minority of Alexander III. Through other marriages the family obtained, for a time, the earldoms of Angus and Athole, so that, by the middle of the 13th century, there were in Scotland 4 earls, 1 lord, and 32 belted knights of the name of Comyn. Within seventy years afterwards this great house was so utterly overthrown that, in the words of a contemporary chronicle, 'there was no memorial left of it in the land, save the orisons of the monks of Deer' (founded as a Cistercian monastery by William Comyn, Earl of Buchan, in 1219). The Comyns perished in the memorable revolution which placed Bruce on the throne of Scotland. Their chief, Black John Comyn, Lord of Badenoch, great-grandson of William, Earl of Buchan, had, in 1291, been an unsuccessful competitor for the crown, as a descendant of the old Celtic dynasty through the granddaughter of King Donald Bane. His son, also called Red John Comyn, was one of the wardens of Scotland, and distinguished himself by his gallant resistance to the English. Suspected by Bruce of betraying him to Edward, Comyn fell under Bruce's dagger, before the altar of the Franciscan friars at Dumfries in 1306; and his kindred went down, one after another, in the struggle to avenge him. John Comyn, Earl of Buchan, the son of Alexander and Isabella de Quenci, was defeated by Bruce in a pitched battle, near Inverury, in 1308, when his earldom was wasted with such relentless severity, that—we are told by the poet

who sang the victories of Bruce—for sixty years afterwards men mourned the desolation of Buchan. Such of the Comyns as escaped the sword found refuge, with their wives and children, in England, where, although they were so poor as to be dependants on the bounty of the English court, they married into the best families, so that, in the words of Mr Riddell, 'their blood at this day circulates through all that is noble in the sister kingdom.' See M. E. Cumming-Bruce, *Family Records of the Bruces and the Comyns* (Edin. 1870).

Conacre is the custom of letting land in Ireland in small portions for a single crop, the rent being paid either in money or in labour.

Conant, THOMAS JEFFERSON, D.D., American biblical scholar, born in Brandon, Vermont, in 1802, graduated at Middlebury in 1823, and afterwards filled chairs of Languages in various colleges and seminaries. In 1836 he published a translation of the book of Job, and in 1857 he was appointed by the American Bible Union to revise the Scriptures. On this work he was engaged until 1875, and he was also a member of the American committee of the Old Testament Company who prepared the revised version. His translations of Gesenius' Hebrew grammar have been standard text-books, and his other works include critical English versions of both Old and New Testament books.

Concarneau, a village of Brittany, on the east coast of Finistère, 15 miles by rail SE. of Quimper. Its inhabitants are largely engaged in the sardine fisheries and in pisciculture. Pop. (1886) 5496.

Concealment is a technical expression in the criminal law of both England and Scotland; as in concealment of pregnancy and birth, concealing treasure-trove, concealing ore from a mine, concealment by a seller from a purchaser of any instrument material to the title with intent to defraud, &c. The concealment of another's crime may expose to a charge of misprision, or it may amount to a charge of accessions after the fact—e.g. where the body of a murdered person is concealed. In bankruptcy, concealment of debtor's property is a serious offence. In civil transactions, but especially in particular contracts, such as insurance and suretyship, where a high measure of good faith is expected, the concealment of a material fact may often invalidate an obligation.

Concealment of Birth. See BIRTH.

Concepcion, (1) a province of Chili, stretching from the Andes to the coast north of Arauco. It is an important agricultural and cattle-raising district, and has valuable coal-mines. Area, 3535 sq. m.; pop. (1885) 182,459.—CONCEPCION, the capital, near the mouth of the Biobio, is one of the most regular and handsome towns of the republic, although it has suffered severely from earthquakes. Its cathedral and several of the other public buildings are noteworthy, and its port, Talcahuano, on Concepcion Bay, is the safest and best harbour in all Chili, and ranks next to Valparaiso as a mart of foreign trade. Pop. 19,000.—(2) CONCEPCION DEL URUGUAY, the former capital of the Argentine province of Entre Rios, on the Uruguay, 180 miles SE. of Paraná by the Entre Rios Railway, with large slaughter-houses and active river-trade. Pop. 10,000.—(3) CONCEPCION, a town of Paraguay, on the Paraguay River, about 260 miles above Asuncion, with trade in *maté*. The official pop. (1879) 10,697, includes the surrounding districts; the town has less than 2000 inhabitants.—(4) The name of several places in Bolivia, the largest being CONCEPCION DE APOLOBAMBA, capital of the province of Campolican, formerly a Franciscan mission. Its Indian popula-

tion cultivate coca and cacao, and collect medicinal barks from the surrounding forests.—(5) CONCEPCION, a town of Mexico, 50 miles W. of Chihuahua, in the upper Yaqui valley, famous for its apples.—(6) CONCEPCION DE LA VEGA, a town of San Domingo, 5 miles SE. of Santiago, with 9000 inhabitants.

Conception, in Psychology. See IDEA.

Conception, IMMACULATE. See IMMACULATE CONCEPTION.

Conception of Our Lady, an order of nuns, founded in Portugal in 1484 by Beatrix de Sylva, in honour of the immaculate conception. It was confirmed in 1489 by Pope Innocent VIII. In 1489 Cardinal Ximenes put the nuns under the direction of the Franciscans, and imposed on them the rule of St Clara. The order subsequently spread into Italy and France.

Conceptualism. See NOMINALISM.

Concert. See MUSIC.

Concertina, a musical instrument invented in 1829 by Sir Charles Wheatstone, the sounds of which are produced by free vibrating reeds of metal, as in the accordion. The scale of the concertina is very complete and extensive, beginning with the lowest note of the violin, G, and ascending chromatically for four octaves. Violin, flute, and oboe music can be performed on the concertina with good effect, and it has an extensive repertoire of music specially written for itself. Every sound in the scale is double, and can be produced either by pulling the bellows open, or by pressing them together. Concertinas are now made in France and Germany, but not so perfectly as in England. The keys in the German concertina are constructed on the same principle as those in the accordion, which play one note when the bellows are expanded, and another when contracted.

Concerto, a musical composition for a solo instrument, with orchestral accompaniments, calculated to give the performer an opportunity to display the highest mechanical skill, as well as intellectual cultivation in the art. The concerto consists of three movements, each of which, like the whole, has a certain character, and like the symphony or the sonata, to which it approximates in form, requires a clear development and treatment of the motives, and a strict adherence to the rules of form. A peculiar feature, usually introduced in the first movement, but frequently also in the last, is the Cadenza (q.v.). When the form is in any way abridged, it is then called a concertino. From the beginning of the last century to the present time, the pianoforte and the violin are the solo instruments mostly used for the concerto. The oldest violin concertos are those by Torelli, the first being published in 1686. The form was developed by Corelli, Tartini, Bach, and Handel, and reached its modern shape under Mozart, though some important modifications were introduced by Beethoven, whose violin concerto and pianoforte concertos are regarded as the highest achievements in this form. Concertos for wind-instruments have been less regarded, and are generally written by the performers themselves, and seldom deserve to be called classical works. Weber's clarinet concerto may be mentioned as one of the few exceptions. There are also concertos for various combinations of solo instruments, such as Bach's for two or more pianofortes, or Beethoven's for piano, violin, and violoncello.

Conch (Gr. *konché*, 'a shell'), a marine shell, especially of the *Strombus gigas* (see STROMBIDÆ); and, in art, a spiral shell used by the Tritons as a trumpet, and still used by some African peoples in war. The native whites of the Bahamas are called

last corrections, 1769); Dr Robert Young's (1880-84) are also much used. The *Englishman's Hebrew and Greek Concordances* (1860) deserve mention. Crutwell's *Concordance of Parallels* dates from 1790. The first concordance of the Koran appeared at Calcutta in 1811. This is superseded by that of Gustav Flügel (1842). The *Complete Concordance to Shakespeare*, compiled by Mrs Cowden Clarke (1845; new ed. Lond. 1881), is invaluable. Concordances have also been prepared to Pope, Milton, Cowper, Tennyson, Dante, Chaucer, and Shelley.

Concordat (Lat. *concordatum*, 'a thing agreed upon'), though sometimes used of secular treaties, is generally employed to denote an agreement made between the pope, as the head of the Roman Catholic Church, and a secular government, on matters which concern the interests of its Roman Catholic subjects. Such concordats may take either of two forms. The pope may, after consultation with the government in question, issue a bull regulating the affairs of the Roman Catholic Church in the country, the contents of the said bull being afterwards ratified by the government and incorporated in the law of the land. Or again, a formal treaty may be drawn up and signed by plenipotentiaries on both sides. Various theories have been held on the obligation of such contracts. Secular jurists have denied that they impose any real obligation on the state, which may annul them at pleasure. Extreme Ultramontanes, on the other hand, have regarded concordats as privileges which the pope grants for the time without entering into any contract properly so called, while the more moderate of Roman canonists recognise a contract binding both sides. As a matter of fact, no modern government can engage that its stipulations with the pope will be respected by its successors in office. Thus the Austrian concordat was secured by the clerical party in 1855 and swept away by their opponents in 1870. The famous and more enduring concordat by which the church in France was re-established after the Revolution was concluded by Napoleon (as first consul) and Pius VII. in 1801.

Concordia, a town of the Argentine state of Entre Rios, on the Uruguay, 302 miles N. of Buenos Ayres by river. It has a custom-house, and a river-trade exceeded only by that of Buenos Ayres and Rosario. There is a railway to Monte Caseros (105 miles), and others to Uruguay and Corrientes are being built. Pop. 10,000.

Concordiæ Formula. See AUGSBURG CONFESSION, CONFESSIONS.

Concrete. There is but little difference between concrete and coarse mortar. The mortar used in the masonry of castles and churches erected during the middle ages is in fact a concrete with small pebbles instead of the larger ones used in modern concrete. Any mixture of lime, sand, and water, with broken stones or bricks, bits of slag, gravel, or other hard material, is called a concrete. The hard lumps are termed the *aggregate*, and the mortar in which they are embedded is called the *matrix*. The mixture varies with the nature and quality of the materials, but it often consists of 1 part of quicklime, 2 of sand, and 5 of gravel. It is better to use such a material as broken stone rather than water-rolled gravel, which has often too smooth a surface. Lime concrete, as the kind above described may be termed, is used principally for foundations, that is, a thick bed of it is formed below the lowest course of stones or bricks in walls, in cases where the ground itself is not sufficiently firm and solid. Not unfrequently, in some countries, walls themselves are formed of concrete, by laying a foot or two of it in height at a time between boards, and giving it some time to harden. It then forms an

artificial stone. Other methods of building walls of concrete are in use (see BUILDING).

Portland cement concrete is made either by mixing it with gravel alone, or more generally by using the cement along with sand and broken stones. The concrete used at Portland Breakwater Fort and at Cork Harbour have nearly the same composition. The cubic yard of it at the former place was made by using of Portland cement 5 cubic feet, of sand 10 cubic feet, and of broken stones (not more than 3½-inch gauge) 28 cubic feet, along with 23½ gallons of water. A concrete with these materials in much the same proportion has been used at other places, but different proportions are also employed. Portland cement being the binding material in this concrete, the question arises whether there is sufficient experience of its durability, especially where it is exposed to the action of sea-water, to warrant its employment in structural works of great or even of moderate size. See CEMENT.

Concrete made of the hydraulic lime from Teil in France, which contains 66 per cent. of silicate of lime, has been employed in the construction of breakwaters and similar works at Cherbourg, Marseilles, and other places. The Teil hydraulic lime is one of the strongest known, and the concrete made with it has resisted the action of sea-water for many years. Ordinary lime concrete does not set under water.

A concrete is made of broken stones and tar, about 12 gallons of the latter being used for every cubic yard of concrete. Bitumen or asphalt is better than gas-tar for this purpose, and either may be hardened by the introduction of dried and pounded lime, clay, or brick-dust. The materials should be heated before being mixed with the tar or bitumen. For backing armour-plates in forts a concrete of cast-iron turnings, asphalt, and pitch has been used. Gravel mixed with rather more than a thirtieth part, by bulk, of iron borings, was successfully used as a concrete at Stranraer pier.

Concrete, a term in logic opposed to *abstract*. A *concrete* notion is the notion of an object as it exists in nature, invested with all its qualities, as any particular flower, leaf, or tree; an *abstract* notion is the notion of any attribute of that flower, leaf, or tree, such as its colour, form, or height; qualities which may be thought of independently of the objects in which they inhere, though they cannot so exist.—The abstract method of handling a subject is adapted to speculation and reasoning; the concrete, to poetic effect and impressive illustration.

Concretion, in Medicine, a formation of solid unorganised masses within the body, either by chemical precipitation from the fluids, or by the accidental aggregation of solids introduced into the system from without. In the former case, a concretion is termed a *Calculus* (q.v.); in the latter, the concretion may be either wholly composed of solids foreign to the body, or these may be mingled with the elements of the secretions, as with mucus, or calculeous matter. Thus beans, peas, needles, &c., introduced into the cavities of the body, have become the nuclei of concretions, by attracting around them mucus, or crystalline deposits from the urine. The most remarkable forms of concretion, however, are perhaps those formed in the stomach and intestines of man and the lower animals, from the more solid and indigestible parts of the food, or of substances improperly swallowed. Thus, young women have been known to acquire the habit of swallowing their own hair to a great extent; and very large concretions have been thus formed, which have proved fatal, by obstructing the passage of food. The

use of oatmeal in large amount has also been found to lead to concretions, especially when eaten coarsely ground and unboiled; such concretions have commonly been found in the intestines. The excessive domestic use of magnesia in the solid form as a laxative has been known to have a similar effect. In certain animals, intestinal concretions are not uncommon, and grow to an immense size; they used to be greatly prized as antidotes, and were used in medicine under the name of Bezoars (q.v.). In certain forms of morbid deposits, such as fibrous tumours (see TUMOUR), and in Tubercle (q.v.), concretions not unfrequently form; they are for the most part composed of phosphate of lime.

Concretionary Structure is a condition in rocks produced by molecular aggregation subsequent to the deposition of the strata, whereby the material of the rock is formed into spherules or balls, as in the concretions of magnesian limestone and the somewhat similar structures occasionally seen in certain tuffs and crystalline igneous rocks. *Concretions* are nodules, balls, or irregular masses of various kinds which occur scattered through the body of a rock, and consist of mineral matter which was formerly diffused through the material of the rock. Some of these concretions are crystalline, as gypsum in clay; others may be spherical, and have an internal radiating structure, as iron-pyrite in shale. Fantastically shaped concretions are not uncommon in certain fine clays; such are the 'fairy-stones' of the country people here, and the 'löss-puppen' of Germany.

Concubinage, the state of cohabitation of a man and woman without the sanction of a formally legal marriage. We find examples in the Old Testament, showing that it was permissible as a relief from a childless marriage. The Roman *concubinatus* was a permanent relation affording freedom from many of the severe marriage restrictions of the civil law. It was a perfectly respectable arrangement, and the woman had a footing in law, although a less dignified position socially than a wife. The offspring, called natural children, came to have limited rights of succession, and could be completely legitimated by subsequent marriage. Augustus, with a view to promote regular marriages, and check the growing licentiousness, enacted a comprehensive marriage-law (*Lex Julia et Papia Poppæa*), which confined concubinage to women of low rank or who had lost their station. Christianity required the complete sanctity of marriage, although the civil law long continued to tolerate separation at pleasure. In the eastern empire concubinage was entirely prohibited by the Emperor Leo. The ancient laws of the Germans recognised, along with regular marriage, a similar informal connection of the sexes still not unknown as Morganatic Marriage (q.v.). The *barraganias* of mediæval Spain and the *hand-fasting* of our own ancestors were merely forms of concubinage. See CELIBACY and MARRIAGE.

Concurrent is a technical term for the person who accompanies a sheriff's officer as witness or assistant.

Concussion of the Brain, in Medicine, is one form of Shock (q.v.)—that, namely, where the symptoms are due to an injury which has shaken or jarred the brain, and stunned the patient, without producing any mechanical injury, so far as can be ascertained, to the brain or skull. It is generally believed that concussion alone can produce severe symptoms and even death, though conclusive proof of this has not yet been given. It is apt to occur from a severe blow or fall on the head, from railway accidents, &c. The symptoms

are those which characterise shock—pale and cold skin, feeble pulse and respiration, with the addition of unconsciousness. This condition may last a few minutes, and be followed by rapid recovery, or may terminate in death. But in most cases it is succeeded by a period of reaction after an hour or more (often ushered in by vomiting, which is thus a favourable symptom), when the skin becomes warmer, the pulse stronger, and consciousness gradually returns. During reaction, congestion or inflammation of the brain is apt to occur. Recovery is usually complete; but sometimes loss of memory, weakening of mental power, undue excitability, or some other sign of impairment of the nervous mechanism, remains for a long time or even permanently.

In regard to treatment, the patient should as quickly as possible be put to bed in a well-aired room, with warm bottles or blankets applied to the body and limbs, and should have injuries to other parts attended to; but beyond this, the less he is interfered with the better. In particular, brandy and other stimulants should on no account be given, except by medical direction; for though occasionally necessary, they do much more harm than good in the great majority of cases. During the period of reaction the patient must be kept very quiet; and for some days at least after apparent recovery he must abstain from alcohol and other causes of excitement, and from mental exertion.

CONCUSSION OF THE SPINAL CORD is due to similar causes acting upon the vertebral column instead of the head. The symptoms vary much with the site and severity of the injury. In many cases they are altogether absent or quite trivial at first, and only attract attention after some hours or days have elapsed; yet, and probably for this very reason, the injury not being treated at first, serious after-effects are much more common than in cases of concussion of the brain. Here also, however, complete recovery is the rule. The treatment must be in the first instance the same as in concussion of the brain.

Concussion of the spinal cord has attracted special attention in recent times owing to its frequent occurrence as a result of railway accidents. The slow and insidious nature of the symptoms presented by many such cases, and the difficulty of deciding whether those symptoms are real, and whether they have resulted from the alleged injury, have given rise to much litigation with respect to damages. The subject is very fully treated by Erichsen, *Concussion of the Spine, &c.* (Lond. 1875).

Condé, in the French department of Nord, situated at the confluence of the Haine and Scheldt, 7 miles NNE. of Valenciennes by rail, is a fortress of the third rank, and gives name to the famous family. Pop. 4067.—CONDÉ-SUR-NOIREAU, a town in the department of Calvados, 23 miles SSW. of Caen by rail. Pop. 6590.

Condé, LOUIS I. DE BOURBON, PRINCE DE, younger brother of Antony of Bourbon, king of Navarre, was born 7th May 1530, representative of an ancient and famous race taking their name from the town of Condé. During the wars between Henry II. and Spain, Condé distinguished himself by his gallantry, winning especial honour at the siege of Metz, the battle of St Quentin, and the capture of Calais from the English—the chief military events of the time. On the accession of Francis II. (1559), the family of the Guises became all-powerful in the state, and Condé and his brother Antony, partly from jealousy of the Guises, and partly from sincere religious conviction, joined the Huguenots, who were now

struggling for legal recognition. To destroy the power of the Guises, and further the interests of the Huguenots, Condé was induced to join the Conspiracy of Amboise (1560). The plot miscarried, and Condé escaped execution only by the death of the king, which by necessitating the regency of the queen-mother, Catharine de Médicis, the bitter enemy of the Guises, changed the policy of the country. Concessions were now granted to the Huguenots, and Condé was made governor of Picardy. The massacre of Huguenots at Vassy by Guise (1562), however, led to the first civil war, and Condé and Coligny gathered an army of Huguenots. At the battle of Dreux, Condé was defeated and taken prisoner, but the assassination of Guise soon afterwards made possible the Pacification of Amboise (1563), by which Condé was released, and the Huguenots were granted liberty of worship. This concession being gradually withdrawn by Catharine de Médicis, the second Huguenot war broke out in 1567. In the south of France Condé had coins struck with the inscription: 'Louis XIII., first Christian king of France.' But at the battle of Jarnac (1569) Condé was defeated and taken prisoner, and immediately after his surrender, shot dead by his bitterest enemy, the Baron de Montesquieu. Condé was a brave leader, and exceedingly popular with his soldiers, but he had neither the lofty character nor the genius of his brother Huguenot, Admiral Coligny.

Condé, Louis II. de Bourbon, Prince of, known as 'the Great Condé,' was born September 8, 1621. Carefully educated by the Jesuits in their college at Bourges, Condé acquired a taste for literature, which he retained all through his life. In his seventeenth year he was introduced at court, and the year following was intrusted by his father with his government of Burgundy. By his marriage, much against his will, to the niece of Richelieu, he gained the support of that minister, and for a time of Richelieu's successor, Mazarin. At this period the Thirty Years' War was still raging, and since 1635 France had been engaged in a protracted struggle with Spain. In 1643, when he was only twenty-two, Condé was appointed to the chief command of the French forces, and in his first campaign defeated the Spaniards at Rocroi in the most brilliant of all his victories. As for more than a century the Spanish armies had been deemed all but invincible, this victory placed Condé at once in the first rank of commanders. In 1644, with his great rival Turenne as his subordinate, in a series of engagements he inflicted at Freiburg a severe check on the Bavarian general, Mercy; and in the following year again defeated the same general at Nordlingen. These successes were gained at an immense cost of life, and in the matter of strategical skill have been disapproved by subsequent military authorities. By the death of his father in 1646, Condé, who had hitherto been known as the Duc d'Enghien, became the head of the house, and was thenceforth addressed as *Monsieur le Prince*. The capture of Dunkirk in 1646, and a great victory at Lens in 1648, in which the famous Spanish infantry were again completely beaten, were the other achievements of Condé during this the first period of his career. The war of the Fronde, occasioned by the quarrels of the court and the parliament, had now broken out, and Condé was required to support the power of the queen and Mazarin. With the aid of Condé the court party came to terms with the Fronde; but Condé himself, who after this service expected to be chief in the state, gave such offence to the queen and Mazarin by his arrogant conduct, that they had himself and his brothers arrested and imprisoned for a year at Vincennes, a proceeding approved alike by the Fronde and the people of Paris. Popular feeling,

however, soon changed in his favour, and grew so strong against Mazarin that he was forced to leave Paris and set Condé at liberty. But Mazarin's power over the queen was still absolute, and Condé, disappointed once more in his ambition, and finding the queen, Fronde, and people once more all against him, retired to Guienne, and raised an army on the plea of rescuing the young king, Louis XIV., from bad advisers. Thus began what is known as the third war of the Fronde. At Bleneau he defeated the royal troops, but was at length forced by Turenne to make for Paris. Here in the Faubourg St Antoine he sustained a defeat which deprived him of all hope of ultimate success, and a peace was concluded in 1653. The terms of this peace, however, were such as Condé would not accept, and deprived of all support in France, he went over to Spain, and for six years served in all the campaigns against his country. Hampered in his action by the Spanish generals, he could effect little against the strategy of Turenne. The battle of the Dunes, near Dunkirk, where Turenne, aided by 6000 of Cromwell's Ironsides, inflicted a severe defeat on the Spaniards, put an end to the war. At the peace of the Pyrenees (1659) which followed, it was said that the affairs of Condé were more difficult to settle than those of Europe. So formidable was he deemed, that the young king found it advisable to restore him to all his honours and estates, and even to his government of Burgundy. Retiring to his estate at Chantilly, Condé remained here till his services were required in another war between France and Spain, when at his suggestion and by his action, Franche Comté was overrun and conquered (1668). The next year, on the resignation of Casimir, king of Poland, Condé would probably have been chosen his successor but for the jealousy of Louis. In 1674 he fought his last battle. This was at Seneffe in Holland, where he had for his opponent William, Prince of Orange. The battle lasted seventeen hours, and both sides claimed the victory. On the death of Turenne in 1675, Condé succeeded him in the command of the army on the Rhine, but his health was now such as to render him unfit for active service. Retiring again to Chantilly, he lived there till his death on 11th December 1686, associating much with the great men of letters of the period, Molière, Racine, Boileau, and La Bruyère. Condé had all his life been noted as a scoffer at religion, but the year before his death he publicly announced his conversion. He took especial pleasure in the society of Bossuet, whose oration on his death, regarded as one of the masterpieces of French literature, has served ever since to throw a deceptive lustre round the name of Condé. He had no political genius, and even as a commander he owed his successes more to the fiery energy of his character than to sheer military talent. There is no ground to suppose that in his public career he was influenced by any other motive than selfish ambition; and in his private character, though he could on occasion display a certain magnanimity, he was in intense degree self-willed and overbearing. When all deductions have been made, however, Condé still remains in the first rank of the Frenchmen of his century.

See Mahon's *Life of Condé*, Fitzpatrick's *The Great Condé and the Period of the Fronde*; *Histoire des Princes de Condé*, by the Duc d'Aumale; also the various *Mémoires* of the period, such as those of Cardinal de Retz, Madame de Motteville, &c.

Condenser is an apparatus in which aqueous or other water is condensed into a liquid form either by the introduction of cold water, as in the condensing Steam-engine (q.v.), or as in distillation, by placing the condenser in another vessel, through which a current of cold water passes. When the water-supply is deficient at sea or on the

coast, salt water may be distilled and condensed. See **DISTILLATION, GAS**.

The **ELECTRIC CONDENSER** is an apparatus consisting essentially of two parallel conducting plates, separated by a layer of non-conducting material or dielectric, employed to receive and retain quantities of electricity greater than either or both of the plates would do alone. The simplest and typical form of condenser is that which was first used by Franklin. It is simply a sheet of glass, C (see fig.), both sides of which, excepting a margin at

the edges, are covered with tinfoil, A and B. To charge such a condenser, one of the sheets of tinfoil, say B, is connected with the ground, E (either by some metallic connection or by being placed on the hand of the experimenter), while the sheet, A, remains insulated. If A be now charged with electricity, positive for example, a negative charge is induced on that side of B nearer A, while an equal quantity passes to the ground. Increasing the charge in A induces a corresponding increase in B. This process, although by means of it large quantities of electricity may be accumulated, cannot go on indefinitely; for on reaching a certain limit, depending on the dimension,

&c. of the apparatus, the nature of the dielectric used, and the difference of potential of the two conducting plates, either a *disruptive discharge* (see **ELECTRICITY**) takes place, or the charge passes off through the insulating supports of the condenser.

All the various forms of condensers satisfy the definition given above. One useful form is that in which the two conducting plates are fixed on the ends of brass rods which pass through brass knobs on the tops of two glass pillars, the dielectric in this case being air. The more common form, however, is the Leyden Jar (q.v.). Another is made up of sheets of tinfoil and paraffined paper, placed alternately in layers; the first, third, fifth, &c. sheets of tinfoil are connected to one terminal, and the second, fourth, sixth, &c. to another.

The *capacity* of a condenser is defined to be that quantity of electricity with which one plate must be charged in order to raise its potential by one unit. It can be shown that, in the case of condensers of the Leyden jar form, the capacity is numerically equal to the product of the outer and inner radii of the coating, divided by the difference of the radii—i.e. is greater as that difference is less. Hence the thinner (within certain limits) the glass between the two coatings of such a condenser, the greater is its capacity.

Condescendence, in the judicial procedure of Scotland, is an articulate statement annexed to a summons, setting forth the allegations in fact upon which an action is founded.

Condillac, ÉTIENNE BONNOT DE MABLY DE, philosopher, was born of a noble family at Grenoble, 30th September 1715. His life was uneventful. As a child his delicate health delayed his progress in education; but in youth he numbered among his friends Rousseau, Diderot, Duclos, &c. Many of his works were composed for his pupil, the Duke of Parma, grandson of Louis XIV.; and he was titular Abbé de Mureaux. He was chosen a member of the French Academy of Sciences in 1768. He died on his estate of Flux, near Beaugency, on August 3, 1780.

A great part of the *Essai sur l'Origine des Connaissances Humaines* (1746), and nearly all the *Traité des Systèmes* (1749), are occupied with a

polemic against innate ideas and abstract systems. He expounds his analytic method in the *Logique* (1780) and the *Art de Raisonner* (part of the *Cours d'Etudes*, in 13 vols. 1755). The *Langue des Calculs* appeared in 1798.

In the *Traité des Sensations*, Condillac uses his analytic method to solve the problem of the origin of our ideas and the formation of the mental faculties. He divided philosophical systems into three classes—(1) Abstract systems, (2) hypothesis, (3) the 'true' system of Locke, which rests on the facts of experience. But in confounding sensation and perception, and endeavouring to base all thought on sensation, he departed from Locke, and became the founder of Sensationalism. To Condillac all reasoning is only a variation of the form of expression. He held that all ideas and mental operations are only transformations of sensation. So he was compelled to put into the primary sensation all that he sought to develop out of it. His curious device of the statue, gradually endowed with the various senses and mental faculties, was for the purpose of isolating sensations. He substituted for the Cartesian test of truth his own criterion of identity. He recognised three kinds of evidence—of fact, of feeling, and of reason; and he affirmed that the same method of analysis is common to all the sciences. Unlike his scholars and followers, the encyclopædists Diderot, D'Alembert, Holbach, Condillac was not a materialist.

Le Commerce et le Gouvernement, published in 1776, treats economy as the science of exchanges, and has much influenced later economists. Condillac was a strong believer in Free Trade. The first of several editions of his *Œuvres Complètes* appeared in 1798. See monographs by Robert (Paris, 1869) and Réthori (1864), and Lewes's *History of Philosophy*.

Condiments, or seasoning agents, are those substances which are employed at table for the purpose of imparting a flavour or seasoning to the ordinary solid or liquid food. The principal condiments are saline substances, such as common salt; acidulous bodies, such as acetic acid or vinegar; oily condiments, such as butter and olive-oil; saccharine substances, such as sugar and honey; and aromatic and pungent condiments, such as mustard, ginger, pepper, and pickles. See **DIETETICS**.

Condition means in law a declaration or provision that upon the occurrence of an uncertain event an obligation shall come into force, or shall cease, or that the obligation shall not come into force until a certain event. Such conditions are known respectively as precedent or subsequent, resolute, and suspensive. Physically impossible, and unlawful conditions in matters of contract annul the obligation to which they are annexed, but in questions under settlements and wills the opposite rule holds, and such conditions are ignored. Conditions in restraint of marriage are considered unlawful only where they are absolute and imposed on persons otherwise entitled to succeed. A potestative condition is the technical name for a condition in the power of one of the parties. It is an important doctrine of contract law that if a debtor does anything to prevent the accomplishment of a condition, he becomes liable as if the condition had occurred. Many most important conditions are merely implied—e.g. in a marine policy that the ship is seaworthy. In bankruptcy, dividends are set aside to meet conditional obligations. Again, in sales on credit, solvency is an implied condition, and where the buyer is declared insolvent, the seller may refuse to proceed. A good instance of a suspensive condition is that of sale on approbation, or on sale and

return. The doctrine of condition in feudal grants is in the law of Scotland very simple. Apart from entails, which were authorised by statute, such conditions must be intended to protect some valuable interest of the superior. Such are the clauses of pre-emption, the now obsolete clause prohibiting subinfeudation, clauses to preserve the plan of a town, or to prevent nuisances. Probably a condition against public-houses is valid, as in the case of the Grangemouth fens by Lord Zetland. If properly inserted and recorded in the titles, such clauses may entitle the superior not merely to refuse an entry under the old law, but to reduce the vassal's title.

Conditions of sale is the name used in England for what are called articles of roup in Scotland. These are generally printed along with the particulars of sale and distributed among those attending the auction. They provide what sort of title the purchaser is to accept. Similarly, conditions are prefixed to catalogues of furniture and books.

Condition. In Logic, denotes that which must precede the operation of a cause. It is not regarded as that which produces an effect, but as that which renders the production of one possible—to some logicians, however, a distinction without a difference. For instance, when an impression is made on wax by a seal, the seal is said to be the *cause*; the softness or fluidity of the wax, a *condition*.

The *Philosophy of the Conditioned* was a phrase brought into use by Sir W. Hamilton to express the inability of the human mind to conceive or reason respecting the Absolute and the Infinite. Our thought, according to him, can only be of the *relative* and the *finite*, of which these terms are but the negations; relativity and finitude are the conditions under which the human intelligence operates. In one of his dissertations on this, he criticised and endeavoured to refute the opposite position as maintained by Cousin—a modification of the previous doctrine of Schelling—that 'the Unconditioned, the Absolute, the Infinite, is immediately known in consciousness, and this by difference, plurality, and relation.' Dean Mansel, in his *Bampton Lectures* (1858), brought Hamilton's doctrine into special prominence, and dwelt on the *relativity of knowledge* as a great fundamental law of the human mind.

Conditional Immortality is a tenet held by a theological school which denies the inherent immortality of the soul, and the consequent doctrines both of eternal misery and of Universalism (q.v.), as contrary to the teachings both of nature and revelation. Its advocates maintain that the Bible sets immortality before men as something to be sought after (Rom. ii. 7), as a divine gift offered on certain conditions (Rom. vi. 23; John, iii. 15, 16), and as a matter of hope and promise in the present life (Titus, i. 2); that this immortality is not a present possession (Mark, x. 30), and is to be realised by the assumption of a spiritual body at the resurrection of regenerate men from the dead (Luke, xx. 35, 36), an event synchronous with the second coming of Christ (1 Cor. xv. 51, 52). Divine testimony, no less than experience, they say, declares unequivocally that man has the same natural life as all other animals (Eccles. iii. 19), and only those who by faith and obedience are united to Christ have the promise of immortality. The Calvinistic doctrine of eternal misery is untenable, the punishment of sin being death or everlasting destruction, to be inflicted subsequent to a judgment after the Lord returns (2 Thess. i. 9, 10). The dogma of Universalism, the only alternative to endless torment if the soul *must* live for ever, is also, they maintain, unfounded, since the punishment of sin (death) is said to be everlasting, like the life which is the reward of the righteous (Matt. xxv. 46). It

is claimed that a succession of eminent and pious men have upheld this doctrine from apostolic times, among whom may be mentioned Justin Martyr, Clement of Alexandria, Irenæus, &c.

Conditional immortality has received considerable impulse in recent years from many able and zealous advocates, notably the late William Leask, D.D., editor of the *Rainbow*, and Rev. Edward White. The Conditional Immortality Mission started in Britain in 1878 has done much, by means of lectures, publications, and annual conferences held in various cities, to disseminate this view. It has an organ, *The Bible Standard*, published monthly by the secretary. Many churches have been organised in Great Britain and its colonies, as well as in America, having conditional immortality as part of their doctrinal basis. The best modern works on the subject are *Life in Christ*, by Edward White; *The Life Everlasting* and *The Unspeakable Gift*, by J. H. Pettingell; *Hades*, by Henry Constable; *Duration and Nature of Future Punishment*, by the same author.

Condom, a town in the French department of Gers, pleasantly situated on a height above the confluence of the Baïse and the Gèle, 20 miles SW. of Agen by rail. It has one fine church, once a cathedral; and was formerly the capital of the extensive Gascon district of *Condomois*, now included in the departments of Landes and Lot-et-Garonne. Bossuet was Bishop of Condom for a year (1669). Pop. 5070.

Condonation, in the legal phraseology both of Great Britain and the United States, means forgiveness granted by the injured party, and may be urged by the guilty party as a defence against an action of divorce on the ground of adultery. See DIVORCE.

Condor (*Sarcorhamphus condor* or *gryphus*), the great vulture of the Andes, one of the largest and most remarkable birds. Among the wide order of Accipitres, or Birds of Prey, the condor is the grandest representative of the family Cathartidae,

Condor.

or New-World Vultures. These may be at once distinguished from Old-World forms by the incompleteness of the partition between the nostrils, by having, to put it more plainly, 'a hole through their nose.' The beak is also constricted at the end of the 'cere,' and the feathers have no 'after-shaft.'

Among these New-World vultures, the condor is chief. Though its size and strength have been often exaggerated, this magnificent bird is probably

the largest of the vultures. The only rival which could dispute this claim is the famous Lämmergeier (*Gypætus barbatus*) of the Alps. The male condor may measure about 3½ feet in length, the female is slightly smaller. The expanse of each wing (said to be 15 feet from tip to tip) is more than twice the length. The general colour is black with a steel-blue sheen, and some of the feathers verge into gray; there is a downy white ruff round the dull-red naked neck. The young birds are covered with whitish down. The beak is long, hooked at the apex, black at the root, yellow at the point and on the sides. The head is naked, and in the male bird bears a large fleshy comb. The eyes look sideways; the 'perforated' nose is characteristic of the family. The voice is limited to a weak sort of snorting. The feet are not well suited for grasping, the hind-toe being very small and hardly reaching the ground. The stories about condors lifting their prey in their feet from the ground are mythical. These birds have their central home in the Andes, but extend to some other mountainous parts of South America. They breed on the heights, laying their two eggs on bare ledges in the months of November and December; the young are unable to fly for a whole year. They descend to the plains to feed on carrion, tearing carcasses with their strong bills; they may also attack lambs and calves, or several together may venture on an adult animal. Their boldness and voracity seem to have been exaggerated. Their voracity is, however, great: Tschudi mentions one in confinement at Valparaiso, which ate 18 lb. of meat in a single day, and seemed on the morrow to have as good an appetite as usual. The condors have great powers of flight, and can soar to immense heights, till, in fact, they are lost in or far above the clouds. They are readily kept in confinement, and may be seen in many zoological gardens.

In the same genus is the rarer King of the Vultures (*S. papa*), inhabiting the wooded plains of South and Central America. It is a smaller bird, reddish-yellow above, white beneath, with bluish-gray ruff, black quills and tail. Its head and neck are covered with variously coloured roughnesses. It owes its name to the way in which it bullies other vultures. Closely allied is the Turkey Vulture (*Cathartes aura*) of North America. This bird, useful as a carrion destroyer, is about 2½ feet in length, black in colour with a purplish sheen, well marked by its carmine and bluish-red head, fleshy neck, and white feet. *C. atratus* is another species from South America.

Condorcet, JEAN ANTOINE NICOLAS DE CARITAT, MARQUIS DE, an eminent French author, was born, the son of a cavalry officer, in the little town of Ribemont, near St Quentin, in the department of Aisne, on September 17, 1743. In childhood he breathed the closest atmosphere of clerical and aristocratic exclusiveness, with the result of making him in after-years the enemy of all privilege and a thoroughgoing sceptic. Condorcet, after distinguishing himself in the Jesuit school at Rheims, began his mathematical studies at the age of thirteen, at the College of Navarre in Paris. His success was rapid and brilliant; and the high approval of Clairaut and D'Alembert determined his future. His *Essai sur le Calcul Integral* (1765) obtained for him a seat in the Academy, and he became perpetual secretary in 1777. He took an active part in the *Encyclopédie*. On the outbreak of the Revolution he made eloquent speeches and wrote famous pamphlets on the popular side, was sent by Paris to the Legislative Assembly in 1791, and in 1792 became president of the Assembly. He voted that the king should receive the most severe punishment except death, and as deputy for Aisne in the National Con-

vention, he voted usually with the Girondists. Accused and condemned by the extreme party, he found refuge in the house of a generous lady, Madame Vernet, for eight months; but driven to change his place of concealment, he was recognised and arrested. Imprisoned in the gaol of Bourg-la-Reine on the 7th April 1794, he was found dead the next morning, whether by disease or poison was never known.

His profession of faith, in a letter to Turgot, which was written when he left college at seventeen years of age, lays stress on moral sympathy as the source of all virtue. His constancy in moral principle was fitly associated with perfect consistency in politics. He raised a great commotion by his attempt to apply the calculus of probabilities in the domain of jurisprudence, and of the moral and political sciences. In his *Progrès de l'Esprit Humain*, written in hiding, he insisted on the justice and necessity of establishing a perfect equality of civil and political rights between the individuals of both sexes, and proclaimed the indefinite perfectibility of the human race. Complete editions of his works have been issued in 1804 (21 vols.) and 1849 (12 vols., containing a biography by Arago). See Morley's *Critical Miscellanies*, Comte's *Philosophie Positive*, and Flint's *History of the Philosophy of History*.

Condottieri (Lat. *conducti*, 'hired'), the name given in the 14th and 15th centuries to the leaders of certain bands of 'free lances' or military adventurers who, for booty, offered their services to any party in any contest, and often practised warfare on their own account purely for the sake of plunder. These mercenaries were called into action by the endless feuds of the Italian states during the middle ages. Among the most celebrated of their leaders were Sir John Hawkwood at Florence (1390, originally an Essex tailor); Francis of Carmagnola (about 1412); and Francis Sforza, who in 1450 became Duke of Milan. The *Compagnies Grandes* in France, during the 14th century, resembled the bands led by the Italian condottieri. They originated in the long bloody wars between France and England, did enormous mischief, and became powerful enough to rout the king's forces in 1361; but ultimately the Constable Du Guesclin persuaded them to seek their fortune in the Spanish service.

Conductivity. See HEAT, ELECTRICITY.

Conductor, the director of the modern orchestra. Though from the earliest days of the orchestra abroad he has always performed his duty by beating time with the baton, the practice was unknown in this country till introduced by Spohr in 1820, at a concert of the Philharmonic Society of London. Previously the orchestra was kept together by the leader of the violins, the conductor simply sitting at the harpsichord or piano with the score before him, occasionally putting in a few chords, or accompanying; but the result was clearly unsatisfactory, and the conducting stick had only to be introduced to gain general acceptance at once. The art of conducting as now practised requires so many qualifications that it may be considered rather as a special gift than an acquirement to be learnt. But few eminent composers have also distinguished themselves as conductors. The greatest recent conductors are Costa, Von Bülow, and Richter.

Conductors and Non-conductors of Electricity. When an electrified body is placed upon a metallic stand, so that it is in metallic connection with the earth, all traces of electrification disappear; but if placed upon supports of glass or ebonite, its charge is still retained, the body then being said to be *insulated*. In the former case, the electric charge having passed to the ground through

the metallic support, the metal is termed a *conductor* of electricity; in the latter, the glass or ebonite is termed a *non-conductor* or *insulator*, since by its means the charge is prevented from leaving the body. This distinction is somewhat artificial, since no substance is known to be either a perfect conductor or an absolute insulator. The substances in frequent use as conductors and non-conductors may be arranged in the following order of their conductivity, beginning with the best: Silver, copper, gold, brass, zinc, platinum, iron, tin, lead, mercury, German-silver, graphite, red phosphorus, mineral acids, saline solutions, seawater, pure water, alcohol, wood, ice, vegetable oils, lime, chalk, camphor, porcelain, wool, hair, silk, glass, wax, sulphur, resin, amber, gutta-percha, shellac, paraffin, ebonite, air and other gases.

It is found that the efficiency of a non-conductor, when used as an insulator in electrostatic experiments, depends very largely on the state of its surface. In a damp atmosphere, glass becomes coated with a thin film of moisture which considerably lessens its insulating power. Hence these experiments succeed better in dry weather; otherwise the apparatus requires to be heated, or the glass insulators employed to be coated with shellac varnish, upon which moisture does not so readily deposit. In metals, conducting power decreases when the temperature is raised; on the other hand, glass, wax, sulphur, and some other bodies which are extremely bad conductors at ordinary temperatures, conduct very much better when raised to a sufficiently high temperature. It has been observed that a series of metals arranged in order of their electrical conducting powers, exhibits the same order as when similarly arranged for their thermal conducting powers; in other words, metals which conduct electricity well, conduct heat well. Also, that when two specimens of the same metal differ in electric conductivity, they differ in thermal conductivity, and in the same way. See LIGHTNING CONDUCTOR.

Condurango is the name of several South American *Asclepiadaceæ* (q.v.), whose bark affords a drug used as a remedy for venomous bites.

Condyle, a protuberance on the end of a bone, serving for articulation with another bone; especially that by which the occipital bone of the skull is articulated to the spine.

Condy's Fluid. See MANGANESE.

Cone. In general, the term *cone* is applied to any surface described by the motion of a straight line which always passes through a fixed point and

O, is termed the *vertex*; the height, OD, the *altitude*; the line, OD, the *axis*; and the circle, ABC, the *base* of the cone. The line, OC, by whose

motion the cone is produced, is termed a *generating line*, or *generator*. In the *oblique* cone, the axis is inclined to the base at an angle other than a right angle. A *truncated* cone is the lower part of a cone cut by a plane parallel to the base.

The lateral surface of a right circular cone is obtained by multiplying half the circumference of the base into the slant height of the cone; the solid content, or volume, is equal to one-third of the area of the base multiplied by the altitude.

In considering the different possible sections of a cone by a plane, it is necessary to remember (as is indicated in the figure) that a cone is really produced in duplicate; that the generators, after passing through the fixed point, O, form another cone, such as OEGF. Different positions of the sectional plane produce different curves, according as it is parallel to the base, a generator, the axis, or parallel to none of these; so, consequently, we have a circle, parabola, hyperbola or ellipse, respectively. See CIRCLE, CONIC SECTIONS, ELLIPSE, HYPERBOLA, PARABOLA.

Cone is a term used in Botany, with considerable latitude and variety of application. The growing point or bud of any ordinary higher plant is of more or less acutely conical shape, and the young leaves at first arise in close succession upon it. But while in vegetative growth the axis usually lengthens and the leaves develop and expand, the onset of reproductive functions may check these changes. In the simplest cases the leaves may become partially modified for pollen or ovule bearing, as stamens or carpels, while the leaf apices do not wholly lose their leafy character and arrangement; thus we have the cone-like male and female flowers of Cycads (q.v.). In the allied conifers, which include the most characteristic cone-bearing trees, the leafy character of the crowded stamens composing the male flower may be almost entirely lost; but in the female the structure of the familiar cones (e.g. Scotch fir, spruce, larch) has been the subject of enormous controversy; since from one point of view it is regarded as a single flower composed of many carpellary leaves (each bearing a biovular placenta on its upper surface); while from the other it must be viewed as an inflorescence of which the crowded bracts bear axillary biovular branches (see GYMNOSPERMS). The cones of Coniferae may vary greatly from their typical shape, witness the almost spheroidal cones of Araucarias, while the number and crowded succession of the leaves in ordinary cones may be much reduced and simplified—e.g. cypress.

The apparent cones which occur in some orders of dicotyledonous plants are always due to a crowding of the inflorescence. Thus, the so-called cone of *Casuarina* (q.v.) is simply produced by the crowding of the fruit; that of *Hop* or *Gale* (q.v.) by the overlapping of the leafy bracts which conceal the small reduced flowers. But the term is with advantage disused by most botanists outside the limits of the Gymnosperms.

Conegliano, a picturesque town of Northern Italy, 31 miles NE. of Venice by rail. It was the birthplace about 1460 of the painter Giambattista Cima, called often Conegliano. Pop. 4682.

Cone-shell (*Conidae*), a family of Gasteropod molluscs, with substantial conical shells. The last whorl of the spiral is much larger than those which precede it and simply form the apex of the cone. The aperture is long and narrow, with a sharp-edged outer lip. The head of the animal has a long proboscis; the 'foot' is long and narrow as the aperture suggests; the respiratory siphon is short and thick. In the living state the shell is covered by a yellowish epidermis, and it is only when this is rubbed off that the great beauty

of the colour and marking is disclosed. During life the inner layer of the shell and the internal partition of the second last whorl undergo more or less absorption. The principal genus, *Conus*, includes some 500 living species, ranging from the

Cone-shell.

Mediterranean to the Cape, but especially at home in the eastern equatorial seas. They creep in relatively shallow water among the rocks and coral reefs, and prey upon other molluscs. Among the numerous species, some are rare, and have been favourite objects of collectors' mania. Many pounds have been paid for single specimens, and *Conus gloria-maris* is said to be 'worth ten times its weight in gold.' *C. cedo nulli* is in

its finer varieties a much prized treasure, and *C. ammiralis* is another favourite, though much commoner form. Numerous fossil species are known from the chalk onwards. Some of the animals are eaten, and the shells often form ornaments, or are worn down into rings and the like. The augur-shell (*Terebra*), the latticed shell (*Cancellaria*), the tower-shell (*Pleurotoma*) are nearly allied genera, often regarded as types of separate families.

Coney Island, barely separated from the south-west angle of Long Island, at the entrance to New York harbour, is a narrow strip of sand, 5 miles long, by $\frac{1}{2}$ mile broad, with a fine beach. It is a crowded place of summer resort, and is connected with New York and Brooklyn in summer by a number of railways and steamboat lines. On the edge of the dunes stand a long row of enormous wooden hotels, and farther inland is the Brooklyn seaside home for invalid poor children. Other structures are a tubular iron pier (1000 feet), a look-out tower (300 feet), and a great number of bathing pavilions, some nearly as large as the hotels. In winter the place is nearly deserted.

Confarreation, a peculiar mode of marriage in use among the Romans, which consisted in the employment of certain words in the presence of ten witnesses, and in the performance of a religious ceremony in which *panis farreus* ('bread made of spelt') was partaken. Various priestly offices, such as that of the *Flamen Dialis*, were open only to those who were born of parents thus married.

Confederate States, the name adopted by the confederacy formed by the eleven southern and slaveholding states which seceded from the American Union in 1860-61, and established a government which lasted till the close of the great civil war in 1865. See UNITED STATES. The Confederate States were South Carolina, Alabama, Florida, Mississippi, Georgia, Louisiana, Texas, Virginia (without West Virginia), Arkansas, Tennessee, and North Carolina.

Confederation, IMPERIAL. See COLONY and CANADA.

Confederation of the Rhine. During the war of 1805, so disastrous for Austria, several German princes, too weak to remain neutral, were forced to ally themselves with France. The first to do so were the Electors of Bavaria and Württemberg, who, in recompense of their services, were elevated to the dignity of kings by the peace of Presburg, 26th December 1805. Finally, at Paris, on the 12th July 1806, 16 German princes formally signed an act of confederation, dissolving their connection with the Germanic empire, and allying themselves with France, under the protectorate of Napoleon. The more important of these 16

princes were—the kings of Bavaria and Württemberg, the arch-chancellor, the Elector of Baden, the new Duke of Cleves and Berg (Joachim Murat), and the Landgraf of Hesse-Darmstadt; later, other princes followed their example, including the king of Saxony, the new king of Westphalia, and the Elector of Würzburg. In 1811 the unpatriotic confederation comprised 4 kingdoms, 5 grand-duchies, 11 duchies, and 16 principalities; covering an area of 125,000 sq. m., with a population of 14,608,877, and an army of 119,180 men. The utter ruin which overtook the French army in the Russian campaign acted like a solvent on the confederation, and the year 1813 saw it vanish like mist in the sudden outburst of German patriotism. See GERMANY.

Conference, a meeting of the representatives of a number of states for political or diplomatic purposes. It is usually distinguished from a Congress (q.v.) as having only the power to discuss and prepare arrangements; while a congress has the power of deciding and concluding. But it is difficult to draw a precise line between the two; thus the Congo Conference at Berlin in 1884 was practically a congress.—Conference is also the name of the supreme synod of the Methodists (q.v.).

Conferva, a genus of lower fresh-water Algae, forming slimy masses or tufts in ponds and stagnant pools, easily recognised by their unbranched filaments, each consisting of a simple row of cells, which are destitute of spiral bands or other distinct differentiation of the contained protoplasm. The filaments do not conjugate, and multiplication appears to take place by rejuvenescence of swarm spores only. See ALGÆ, and Cooke's *Handbook of British Algae*.

Confession, in Roman Catholic theology, means a declaration of sins to a priest in order to obtain absolution. The word, however, has borne very different meanings at different times, and the changes in sense mark important stages in the development of discipline and doctrine. St James (v. 16) speaks of that spontaneous confession which Christians make 'one to another' out of humility and brotherly love; and, much in the same spirit, Origen (Hom. in Ps. xxxvii.) recommends the sinner to seek out a physician 'learned and merciful,' to whom he may disclose his wounds, and from whom he may get advice. In all this there is no question of strict obligation on the one hand, or of priestly power upon the other. Still, even before Origen's time, the word had acquired a new signification. From the close of the 2d century at latest the church marked out for special reprobation those sins which were called 'mortal'—viz. murder, idolatry, and adultery. The guilty person was required to make public confession, he was subjected to penitential exercises, and was either excluded during life from the communion of the church, or readmitted, after long discipline, by the bishop, who imposed his hands upon him. The list of 'mortal offences' was extended during the 5th and the following centuries to all crimes which the Roman law punished with death, exile, or grave corporal penalty, and Leo I. (440-461 A.D.), in a famous letter to the Bishops of Apulia (Ep. 168), substituted private confession to the priest for public confession to the congregation. But the essential points of difference between ancient and modern or sacramental confession remained. In the former, the church only required confession to man of certain enormous offences, and left the mass of sins which are now called mortal to the judgment of God; and she exercised the power of 'binding and loosing' by excluding sinners from, and readmitting them to, her communion. Such power is really inherent in every society, though

of course the church claimed to hold it by divine commission (Matt. xvi. 19, xviii. 18; John, xx. 22, 23), and insisted on the serious consequences which it involved. We can trace the faint beginnings of the modern system in the practice which prevailed in monasteries and nunneries of confessing breaches of the rule to the superiors (Jerome, *De Reg. Monachorum*; Basil, *Reg. Brev.*), and in the growing habit of seeking advice from priests by secret confession. The thirty-third canon of the Council of Châlons, which was held 813 A.D., throws great light on the state of things then existing. Some, the council says, maintain that 'sins should be confessed to God alone,' others to God and to the priest. The council finds no fault with either view, and remarks that confession to God purges the conscience from sin, while confession to the priest teaches the penitent 'how his sins are to be purged.' Even Peter Lombard, the great theological authority of the 12th century (*In Sentent. lib. iv.*), occupies the same ground as the Council of Châlons; and Aquinas (*Supplement to the Summa*) admits that in Lombard's time the necessity of confessing all mortal sins to the priest was an open question. Meantime, the fourth Lateran Council in 1215 (can. xxi.) had required all the faithful who have come to the years of discretion to confess their sins at least once a year to their parish priest, or with his leave to another priest. The doctrine received its final form in the Council of Trent (Sess. xiv.). The council explains 'mortal sins' to mean all sins, 'even sins of thought' which separate the soul from God. It declares that for mortal sin after baptism, confession to an approved priest, in act if possible, in desire if a priest cannot be had, is by divine institution the one and only remedy. This confession must embrace every mortal sin which can be recalled after careful self-examination. Further, it declares that the secret confession of mortal sins has always been practised in the church, and whereas in Peter Lombard's time Roman Catholics were free to hold that absolution was no more than a declaration of forgiveness by God, the council condemns this opinion under anathema. But it is careful to add that confession and absolution, in order to avail, must be accompanied by sincere sorrow before God for sin past, and a firm purpose of amendment. By the present canon law, Roman Catholics living in the world may choose any priest approved by the bishop as their confessor. The confession of slight or venial sins remains a matter of counsel and not of precept.

Confession to a priest is prescribed by the Greek and most of the Oriental churches, and the Church of England recommends private confession in the case of the sick, though it has never enforced the use of it. In 1873, 483 Anglican clergymen presented a petition to Convocation for the education, selection, and licensing of duly qualified confessors. That petition fell flat; but confession is regularly practised among a considerable section of the English communion. The Lutherans at first were inclined to retain some sort of private confession, but they were content with confession of a general kind, and have allowed it to fall into disuse or become a mere form. It is entirely rejected by Presbyterians, Methodists, Congregationalists, Baptists, and others.

The 'seal of confession' is the obligation which binds the priest to make no use whatever outside of the confessional of the knowledge acquired there. It is imposed under severe penalties by the fourth Lateran Council. See CONFIDENTIALITY.

Confession, in civil procedure by English law, is a formal admission or avowal of a fact, as when a defendant alleges a ground of defence which has arisen since the commencement of an action, and the plaintiff confesses the defence—i.e. admits the

truth of the defendant's allegation. In Scotland, a party to an ordinary civil action may be called on to confess or deny any relevant matter of fact, and if he refuse, he will be held as confessed. Where a statement within the opposite party's knowledge is averred upon one side, it is held as confessed by the other unless specifically denied. In criminal law, a confession is an admission of guilt. In England, a confession by a criminal made in the course of a judicial proceeding is sufficient, if plenary, to found a conviction, as where a prisoner pleads guilty. An extra-judicial confession, if freely made, may be admitted as evidence. In Scotland, a confession made by a criminal in presence of a judge will be admitted as evidence; but is not held as equivalent to a confession by the panel in presence of a jury, which is conclusive evidence against him. In the United States also confession is evidence, if voluntary and made without promise of reward or threat of punishment, and that whether made before or after apprehension and commitment; generally confession without corroboration is insufficient, but in one or two states the jury may convict without corroboration. As to confession on trial, see PLEADING, TRIAL; as to confession before the examining magistrate, see DECLARATION; and for Judgment by Confession, see COGNOVIT.

CONFESSIO AND AVOIDANCE, in pleading at common law, in England, is the admission of the allegation of the opposite party, but with the addition of some circumstance which deprives it of legal effect, as, for instance, the admitting that an assault was committed in self-defence. Since the passing of the Judicature Acts of 1873 and 1875, pleas in confession and avoidance have technically fallen into desuetude. See PLEADING.

Confessional, the seat or recess in which the priest sits to hear confession in a Roman Catholic church. It is probable that the confessionals in English churches, previous to the Reformation, like those still often found in Catholic use, were slight wooden erections, because they have so entirely disappeared that their form is a matter of dispute among ecclesiologists. It would seem that confessionals were not always used, as in an old painting on the walls of St Mary's Chapel, Winchester, a woman is represented kneeling to a priest, who is seated in his stall. The confessional commonly has a door in front for the priest to enter by, and an opening on one or both sides, like a small window, with a grating of wire or zinc, for the penitents to speak through.

Confessions of Faith are generically identical with Creeds (q.v.). If any distinction be made, it is the merely accidental differentiation that creeds are shorter, and that confessions of faith are generally polemical as well as didactic in their character and aim. Such a distinction, it is found, actually obtains in practice, and confessions of faith, as thus distinguished from creeds, are so numerous and varied as to call for separate attention.

Confessions of faith may be defined as authorised summaries of a church's belief, and standards of its faith and doctrine. In all Protestant churches, however, they are regarded as subordinate standards, ranking under the Scriptures, which are recognised as the only supreme 'rule of faith and life.' Their object is to present the cardinal truths of revelation in a connected and logical form; especially if these be controverted; while at the same time they afford a basis of association and a bond of unity for Christians. As they are the result of the conflicts of a church with error, confessions of faith vary in their doctrinal comprehensiveness, are more or less gradual in their

growth, and are significant and important features in its history.

Prior to the era of the Reformation in Europe, the public formularies of the Christian church were generally termed creeds. It was the rise of Protestantism that evoked confessions of faith as we now understand the name. Among the first to formulate these were the Swiss at Zurich, where, in 1523, Zwingli wrote his *Sixty-seven Articles* or *Conclusions*. To Luther and Philip Melancthon, however, is due the honour of drawing up the first authoritative evangelical formulary, the *Augsburg Confession* (q.v.), by the adoption of which the Lutheran princes, with their states, in 1530, finally broke with Rome. It was followed by the *Apology of the Augsburg Confession*, drawn up by Melancthon, and recognised as a confession in 1532. Later confessions of that church are the *Articles of Smalcald*, prepared in 1537, the *Saxon Confession*, and the *Württemberg Confession*, both published in 1551. But these were superseded in 1580 on the adoption of the *Form of Concord* (*Formula Concordiæ*), which is the most representative symbol of the Lutheran Church.

The German Reformed Church, which sprang up side by side with the Lutheran, and stood midway between it and the Calvinistic bodies, issued in 1530 the *Tetrapolitan Confession*, so called because sent forth in name of the four cities of Strasburg, Constance, Memmingen, and Lindau. It was written chiefly by Bucer. Among other confessions officially recognised by this church, or local portions of it, were the Confession of Anhalt (1581); the Confession of Nassau (1578); the *Consensus of the Ministry of Bremen* (1598); the *Hessian and Heidelberg Confessions* (1607); and the *Declaration of Thorn* (1645).

In Switzerland, the labours of Zwingli were followed by the publication in 1534 of the *First Confession of Basel*, prepared by Ecolampadius and Myconius. To it succeeded in 1536 the *Second Confession of Basel*, better known as the *First Helvetic Confession*. It was superseded in 1566 by the more comprehensive *Second Helvetic Confession*, which was written by Bullinger, and obtained official sanction in Scotland, Hungary, France, and Poland. Calvin left his mark on confessional literature in, among others, the *Consensus of Zurich* (1549); in the *Consensus of Geneva* (1552), which is a treatise written mainly in defence of the doctrine of predestination; and in the *Gallican Confession*, which he prepared in conjunction with his pupil, Antoine de la Roche Chandieu (Sadcel). The latest Swiss confession is the *Helvetic Consensus Formula*, written in 1675, by Heidegger of Zurich. It is thoroughly Calvinistic, and was drawn up in defence of the conclusions of the Synod of Dort.

The *Gallican Confession*, was adopted by the French Reformed Church in 1559, and after revision was ratified at the Synod of Rochelle in 1571, whence it is sometimes called the *Confession of Rochelle*.

The *Belgic Confession*, drawn up principally by Guido de Brès in 1561, has since then been, and still is, the authoritative standard of the Dutch and Belgian Reformed churches. The Arminian controversy occasioned the meeting of the Synod of Dort in 1618, and the issuing of the *Canons of Dort* in the following year. These canons were adopted as symbolical by the Dutch and French Reformed churches.

But confessions have not been peculiar to the Protestant Church. Influenced by the Reformation, the Greek Church adopted the *Orthodox Confession of Mogilas*, the metropolitan of Kiev (died 1647), who drew it up in a catechetical form as a protective measure against both Protestant and Roman Catholic churches. Recast by Syrgia, the

metropolitan of Nicæa, it became in 1672 the confession of the whole Greek Church. At the same time the anti-Calvinistic *Confession of Dosithens* was promulgated by the Synod of Jerusalem. Similarly, the Roman Catholic Church published the *Canons and Decrees of the Council of Trent* in 1564, to which were added in 1854 the decree of Pius IX. on the Immaculate Conception, and in 1870 the Vatican Decrees. See ROMAN CATHOLIC CHURCH.

In Britain the chief confessions are the *Scotts Confession*, consisting of twenty-five articles, drawn up by John Knox in 1560, and adopted by the Church and kingdom of Scotland; the *Thirty-nine Articles of the Church of England*, adopted in 1562; the Irish Articles, one hundred and four in number, prepared by Archbishop Usher, and adopted by the Irish Church in convocation at Dublin in 1615, but superseded by the *Thirty-nine Articles of the Church of England* in 1635 (see ARTICLES); and the *Westminster Confession of Faith*, emitted in 1647 by the Westminster Assembly of Divines (see WESTMINSTER). This confession has become identified with Presbyterianism among all the English-speaking populations of the globe. Its theology was also adopted with some modifications by the Congregationalists and a section of the Baptists. It was ratified by the English parliament in 1647, but in England its influence waned with the decline of Presbyterianism during the Commonwealth and the reign of Charles II. By Scotland, in furtherance of the uniformity agreed upon in the Solemn League and Covenant, the Westminster Confession was cordially received and adopted in place of that of 1560. It was approved by the General Assembly in 1647, with the modification of but one section regarding the magistrate's power *circa sacra*, was ratified by parliament in 1649 and again in 1690, and continues to be the common symbol of the Church of Scotland and of the churches which have seceded from her communion, save in the case of the United Presbyterian Church, which in 1879 modified its acceptance of the Confession by a Declaratory Statement regarding certain of its doctrines.

The Westminster Confession consists of thirty-three chapters, is thoroughly Calvinistic in its teaching, and is in many parts stated in terms designed to counteract the principal errors of the time. Beginning with the canon of Scripture, it surveys the entire field of theology, deals also with the relations of the state to the church, the constitution of the church itself, and concludes with the topics of death, the resurrection, and the last judgment. Its precise logic, its clear, dignified and powerful diction, and its constant reference to Scripture in proof of its statements, tended greatly to beget that influence to which it attained.

Confessions of faith are now the subject of a voluminous literature which is fully utilised in the *History of the Creeds of Christendom* (3 vols. 1876), by Dr Philip Schaff of New York, and his *Harmony of the Reformed Confessions* (1877). A valuable historical appendix, with special reference to the Presbyterian Church, is given in the Report of the Second General Council of the Presbyterian Alliance (1880). See also under CREEDS.

Confessor. See CANONISATION.

Confidentiality. in Law. The most common instance of confidentiality is in the case of those communications between a client and his legal adviser which neither of them can be called on to produce in a suit, and upon which no action of damages can be founded. The privilege applies to letters written by the lawyer to his client relating to a suit which is either pending or contemplated; but to what extent it covers other business communications is a question on which there are

conflicting authorities in Scotland. In England the rule is not qualified by reference to impending litigation. The same privilege is extended to the communications of several parties, or of their counsel and agents engaged on the same side of a cause, and made with a view to their joint prosecution or defence. Where a party placed in such circumstances is examined as a witness, he will be entitled to decline answering questions as to such communications, and even bound to do so, unless the privilege is waived by the other party interested. Such confidential communications cannot, as a rule, be made the ground of an action for libel or slander, because there is a presumption against malice, which may, however, be rebutted. It is on the same principle that a master is protected who, when called upon for the character of a servant, charges him with a theft. With a view to preserving the freedom of domestic intercourse, and from a belief that the testimony of near relatives in favour of each other was worthless, it was formerly the habit to reject them as witnesses. The practice in England for a long time, however, has been to admit, and even to exact their evidence, making allowance, in appreciating its value, for the circumstances in which they are placed. The same principle has latterly been followed in Scotland; and the only exceptions which have been retained by the Evidence Acts of 1853-54 are, that neither the parties themselves, nor their husbands or wives, shall be competent or compellable to give evidence in criminal proceedings in which they are accused, nor to answer questions in a civil suit tending to criminate themselves or each other, or to reveal matters which they have communicated to each other during marriage. But where the issue for trial involves the terms on which the spouses lived, &c., they may be examined. Such communications remain confidential, although the marriage has been dissolved by death or divorce.

From the 4th and 5th centuries the 'Seal of Confession' was held to be inviolable, and no priest could be called upon, under any circumstances, to reveal facts which had been confided to him under its sanction. To this the case of treason was an exception in England, even in Roman Catholic times. The capitularies of the French kings and some other continental codes of the middle ages prohibited the attendance of clergy as witnesses in court. In Roman Catholic countries the privileges of the confessional remain unaltered, although a priest may state that the accused has submitted to penance. The duty of disclosure, however, is enforced in all cases in which the confession has reference to a future crime. In England no special privilege whatever is extended to the Roman Catholic confessional; and the question as to how far a confession made to a clergyman for the purpose of obtaining spiritual comfort and consolation is protected was long considered doubtful. The rule has, however, been settled for some time that clergymen are not entitled to the same privilege as legal advisers; though it has often been advocated as advisable to extend the rule to clergymen, including Roman Catholic priests. In Scotland the point has never been decided, evidence of the kind in question, when not indispensable for the ends of justice, being generally either withheld or withdrawn. It has been decided in England that communications to a medical man, even in the strictest professional confidence, are not protected from disclosure; and the same is the case in Scotland. Factors, bankers, and intimate friends are certainly not within the protection of the rule. Confidentiality exists as to the great majority of official reports and state papers.

In the United States, members of the legal profession are privileged, and, as a rule, what a client

says to them cannot be disclosed except the right of confidentiality be waived. Interpreters stand in the same relation as attorneys. Confessions made to a clergyman or priest in some states are privileged by statute, but generally it is otherwise. By a statute of the state of New York, ministers of the gospel and priests of every denomination are forbidden to disclose confessions made to them in their professional character; and in the course of discipline enjoined by the church, similar statutes exist in Missouri, Wisconsin, Michigan, and Iowa. Communications made to a physician are not as a rule privileged; but in some states confidentiality is recognised. Communications between a husband and wife are privileged from disclosure, on the grounds of public policy and the good order of society. See PRIVILEGE.

Confirmation, a Latin word which signifies 'strengthening.' In the ancient church, the rite so named was administered immediately after baptism, if the bishop happened to be present at the solemnity; and in the Greek Church it is still made part of the baptismal rite, being administered then by the priest by means of unction with chrism consecrated by a bishop. In the Roman Catholic Church, for the last 300 or 400 years, the bishops have interposed a delay of seven years after infant baptism; in the Lutheran Church, the rite is usually delayed for from thirteen to sixteen years; and in the English Church, from fourteen to eighteen years. There is, however, in the latter church no limitation of age, other than such as is indirectly implied by the exaction of a specified amount of religious knowledge as a qualification for the rite. Confirmation may be administered at an earlier period, if a family is about to emigrate; and persons are confirmed up to sixty or seventy, if they choose. The ceremony consists in the imposition of hands by the bishop, accompanied by an invocation of the Holy Ghost as the comforter and strengthener. But both in the Lutheran and in the English Church, the ceremony is made the occasion of requiring from those who have been baptised in infancy, a renewal in their own persons of the baptismal vow made for them by their godfathers and godmothers, who are thereby released from their responsibility. Properly, none can partake of the Lord's Supper, in these churches, unless they have been confirmed. In the Roman Catholic Church, confirmation is held to be one of the seven sacraments, and in its administration chrism and the sign of the cross are used; and instead of the imposition of hands, the person confirmed receives a slight blow on the cheek, to remind him that he must in future suffer affronts for the name of Christ. Catholics usually take a new name at confirmation, which should be the name of some saint whom they choose for their special patron. In the Thirty-nine Articles of the Church of England, confirmation is declared not to be one of the sacraments, and the above ceremonies have been discontinued since the Reformation.

Confiscation, in Scottish law, has been applied to the forfeiture of lands or goods to the crown, as part of the punishment for certain crimes, such as murder and treason. But more commonly the word is used in international law to signify the appropriation of goods or ships belonging to a hostile state, or its subjects, generally as a punishment for an attempted breach of blockade. See ESCHEAT.

Conflict of Laws. On the breaking up of the Roman empire into separate kingdoms, as many systems of jurisprudence, more or less dissimilar, arose, and were administered side by side. But owing to commercial intercourse and intermarriage many persons held property in more

countries than one; many possessed two nationalities by birth, and more than two—if nationality could be acquired by residence and interest in a foreign state. In such circumstances it often became an object of the utmost importance to individuals to ascertain, and of the greatest difficulty to lawyers to determine, whether the laws of one state or of another were to govern questions of sale, succession, status, and the like. As no state could vindicate its jurisdiction beyond its own boundaries without being guilty of an act of aggression, it became absolutely indispensable that certain general rules should be fixed upon in order to prevent the danger of national hostilities on trifling occasions. The elaboration of these rules constituted a new branch of jurisprudence, to which the title of Private International Law has been given. Many of the classical treatises on the subject—e.g. Huber and Story—are entitled the *Conflict of Laws*. Other writers, such as Savigny, Bar, and Kœlix, use the term 'Private International Law.' From the partially independent character which belongs to the different states which constitute the American Union, the labours of the continental jurists in international jurisprudence have been carefully adapted to the requirements of that country; and it is consequently to America and to continental Europe, rather than to British writers, that we must look for systematic works on this subject. See INTERNATIONAL LAW.

Conformable Strata are beds which lie parallel to each other, the accumulation of the upper strata having followed the deposition of the underlying beds without any break or prolonged interruption. Conformity thus points to a continuity of the same physical conditions.

Confraternities. See BROTHERHOODS and GUILDS.

Confronté, in Heraldry, is a term applied to two animals facing or fronting one another.

Confucius, the name by which the great Chinese sage is known, is a Latinised form of the Chinese *K'ung Fū-tszé* (孔夫子) or 'the Master K'ung,' K'ung being his clan or family name, and Fū-tszé the denomination applied to him by his disciples after he had become a teacher, and gathered around him a school of ardent and inquiring spirits, to whom he communicated his views on the ancient literature and history of their country, and on the principles of human duty. As a child, he received the *postnomen* *Ch'ü*, and when grown up he was called *Chung-ni*, marking his place in the household. His birth took place, according to the most authoritative account, in 551 B.C., in the village of Ch'üeh, in the state of Lû, a part of the present province of Shantung.

The K'ung family had migrated to Lû from the dukedom of Sung, and were a branch of the ruling house of Sung. The lineage of Confucius is thus traced through the dukes of Sung to the kings of the Shang or Yin dynasty, and through them again, up among the mists of antiquity, to the sovereign Hwang Ti, whose reign is said to have commenced in 2697 B.C. His father, known to us by the name of Shü Liang-heh, was commandant of Tsâu, and a soldier distinguished for his strength and daring. In his old age he contracted a second marriage with a young lady of the Yen family, and of her was born the sage in 551.

Liang-heh died in the child's third year, leaving his mother and him in straitened circumstances. He has described his own mental growth till he was seventy, when he 'could do whatever his

heart prompted, without transgressing what was right,' and tells us that 'at fifteen his mind was set on learning, and at thirty he stood firm in his convictions.'

At nineteen he married, going for his wife to the Chien-kwan family in his ancestral state of Sung, and in the year after, his son Li was born. Besides this son Li, Confucius had two daughters.

Confucius.

(Reduced fac-simile of a rubbing from a marble slab behind his temple at Kio-foo-hien).

About the time of his marriage we find him in humble offices, in charge of the public stores of grain, and of the public herds, performing efficiently his functions, and allowing nothing beyond or higher than them to occupy his attention. In 531 B.C., when he was in his twenty-second year, he commenced in Ch'üeh-lî his career as a teacher. He continued in his native state till 517 B.C., with the exception of a short visit to the capital at Loh, where he is said to have met with Lâo-tszé (q.v.). In 517 Lû fell into great disorder. The Duke Châo being worsted in the struggle, fled to the neighbouring state of Ch'î, and thither Confucius also for a time repaired.

Returning to Lû, he remained there for sixteen more years without being called to any official employment. Duke Châo died in exile in 510 B.C.; and his younger brother and successor, Duke Ting, in 501 B.C. appointed Confucius governor of the town of Chung-tû, where a marvellous reformation in the manners of the people speedily took place. The next year saw him first minister of works for the state, and next minister of crime. The government was now conducted for three years according to his counsel. 'He strengthened,' we are told, 'the ruling house, and weakened the ministers and chiefs. A transforming government went abroad. Dishonesty and dissoluteness were ashamed, and hid their heads. Loyalty and good faith became the characteristics of the men, and chastity and docility those of the women. Strangers flocked to Lû from other states.' Confucius was the idol of the people.

But this success did not last long. The prosperity of the state awakened the jealousy and fears of its neighbours. The marquis of Ch'î cunningly sent to Duke Ting a present of beautiful courtesans and fine horses, and a breach was made between Confucius and his ruler. His counsels were no longer sought. He determined to leave Lû and visit other states. Accordingly in 497 B.C., when he was now

in his fifty-fifth year, he went forth from Lû, nor did he return to it till 485 or 484 B.C.

During this long period he visited many states, attended always by a company of his disciples. His fame had gone before him, and many of the princes would have received and supported him, but he would not settle where he could not obtain free course in carrying out his principles. Repeatedly he and his companions were in straits, and even in peril of their lives. Once they were assailed by a mob, who mistook him for an officer by whom they had been oppressed. But while the others were alarmed, he calmly said: 'After the death of king Wân, was not the cause of the right way lodged in me? While Heaven does not wish this cause to perish, what can the people of K'wang do for me?' Another time, in somewhat similar circumstances, he said: 'Heaven has produced the virtue that is in me; what can any man do to me?' Such was his belief concerning himself and his mission. He never pretended to be anything more than man, but he *knew the right way*, the way for the individual to perfect himself, and the way for the highest ruler to rule, so as to make men happy and good. One of the princelets through whose territory they passed asked his disciple Tsze-lû how he would describe the Master, and the disciple gave him no reply. When he told the Master of the question, Confucius said: 'Why did you not tell him that I am a man who in his eager pursuit of knowledge forgets his food, and in the joy of its attainment forgets his sorrows, and who does not perceive that old age is coming on!' He was then probably in his sixty-fifth year.

Duke Ting of Lû died in 495 B.C., and was succeeded by his son Duke Ai, who in his tenth year sent a message of recall to the sage in Wei. The ruler and his ministers received him respectfully, but he can hardly be said to have re-entered political life. Only a few more years remained to him, during which he is said to have put the finishing hand to his labours on the ancient writings, and been specially assiduous in the study of the *Y-king*. He tells us himself that he reformed the music to which the ancient odes were sung, and digested the odes themselves, giving to the pieces in the principal parts of the collection their proper places. He must have occupied himself also with the composition of the only classical work which is assigned to his own pencil—the *Ch'un Ch'iu*, embracing the events in the history of Lû from 722–481 B.C. The latest entry in the work is that in Duke Ai's fourteenth year (481 B.C.). He died on the 11th day of the 4th month in 479 B.C.

In the *Confucian Analects*, or memorabilia compiled soon after his death from the reminiscences of his disciples, we have abundant information of the Master's Sayings and Doings, and they can be added to from the supplements to the *Ch'un Ch'iu*, the *Narratives of the School*, portions of the *Books of Ritual Usages*, and the memoir by Sze-ma Ch'ien. There are other works about him, but all containing more or less of the legendary element, evidently introduced after the Buddhistic literature became known to the Chinese. Of no ancient personage do we have fuller information than we possess of Confucius, and no other can we fashion more completely to ourselves. One whole book of the *Analects* is occupied with his personal characteristics, his deportment, his eating, his dress. It shows him to us at his ruler's court, in his intercourse with his disciples, in his carriage, at his table, in his bed. The disciples tell us that there were four things from which he was free—foregone conclusions, arbitrary determinations, obstinacy, and egoism; that there were four subjects which he avoided in talking with them—extraordinary things, feats of strength, rebellious

disorder, and spirits; that there were four things which he taught them—letters, ethics, lead-heartedness, and truthfulness; that there were three things of which he seldom spoke—profitableness, the appointments (of Heaven), and perfect virtue; and that there were three things in regard to which he thought the greatest caution should be exercised—fasting (as preliminary to sacrifice), (going to) war, and (the treatment of) disease.

It is often said that Confucianism is a system of morality without religion. That he was emphatically a moral teacher is indeed true; and his greatest achievement as such was his formulating the golden rule, 'What you do not wish done to yourself, do not do to others.' He acknowledges in one passage that he himself failed in taking the initiative in obeying it. But this high morality was not without a religious sanction. If it be the requirement of man's nature on a correct analysis, yet that nature is the distinguishing endowment conferred on man by Heaven or God, and obedience to its requirements is obedience to the will of God. The first sentence of the *Chung Yung*, the treatise written by Confucius' grandson, is this: 'What Heaven has conferred is *the Nature*; an accordance with this nature is what is called *the Path*; the regulation of this path is what is called *the Teaching*.'

But how is it that we do not find in the utterances of Confucius the expressions of a fervent piety, and that in his many exhibitions of the character of the *Chün-tszé*, his superior, model, or ideal man, he does not show him to us communing with God, confessing his own unworthiness, and imploring his forgiveness? These defects in his teaching we must admit. The explanation of them lies probably in this, that the direct worship of God was confined in the ancient religion of China, as it still is, to the sovereign as the parent and priest of the people. Speaking of the greatest religious services of the ancient sovereigns, Confucius, as is recorded also by his grandson, delivered the important judgment that in those services, 'in the ceremonies of the sacrifices to heaven and earth, they served God.' He probably thought that it was not for him as a subject to be taking on his lips the Great Name; he was, as he said, merely a 'transmitter and not a maker.'

It has been said that Confucius discountenanced prayer; but the passage referred to in support of the charge is not sufficient to bear it out. Equally reticent and enigmatic were his replies to the well-known question of the same disciple about the services offered to the spirits of the departed, and about death itself. He did not rise to the acknowledgment of the principle enunciated by Láo-tszé, that kindness is to be returned for injury, and evil overcome with good, but laid down to his disciples the dictum that they should 'recompense injury with justice, and return good for good.' And his own special work, the *Ch'un Ch'iu*, is evasive and deceptive; according to Kung-yang it often 'conceals (the true nature of events) out of regard to the high in rank, to kinship, and to men of worth.' The person in the past to whom he looked back with the greatest reverence was the Duke of Cháu, the legislator and consolidator of the dynasty of Cháu (died 1105 B.C.).

He died lamenting the failure of his life; but he was hardly gone when his merit began to be acknowledged. Duke Ai, who had been unable to follow his counsels, caused a temple to be built, where sacrifices, or offerings, should be presented to the sage from generation to generation. In one aspect of it, the brief reign of Shih Hwang-Ti, the first imperial sovereign of China, was a contest between him and Confucius, in which the latter prevailed. The first emperor of the Han dynasty,

in 197 B.C., in passing through Lû presented to him 'a great offering.' Succeeding dynasties have done honour to him by titles and offerings; and by none has this been done so much as by the present Manchû-Tartar dynasty, intending thereby, it is believed, to reconcile the Chinese people to their sway. The Khang-hsi emperor, the greatest of its monarchs, after visiting his temple, and presenting the offerings, prostrated himself three times before the sage's image, bowing his head each time thrice to the ground. The law requires that there shall be a temple to Confucius in every prefecture, sub-prefecture, district, and market-town in the empire. These temples are not to Confucius alone. They are not *pantheons*, for he has never been deified; but the worship paid to him in them is extended to several of his disciples and a crowd of his most distinguished followers, amounting to more than one hundred and fifty names in all, selected by imperial decree from the literati and officers in all the course of time.

Twice a year, on a certain fixed day, the emperor goes to the imperial college in Pekin, and does homage to Confucius. The words of the principal prayer or address on the occasion are the following: 'On this month of this year, I, the emperor, offer sacrifice to the philosopher K'ung, the ancient Teacher, the Perfect Sage, and say, O Teacher, in virtue equal to heaven and earth, whose doctrines embrace both time past and present, thou didst digest and transmit the six classics, and didst hand down lessons for all generations! Now in the second month of spring (or autumn), in reverent observance of the old statutes, with victims, silks, spirits, and fruits, I offer sacrifice to thee. With thee are associated the philosopher Yen, Continuator of thee; the philosopher Tsang, Exhibitor of thy fundamental principles; the philosopher Tsze-sze, Transmitter of thee; and the philosopher M'ang, second to thee. Mayest thou enjoy the offerings!'

The descendants of Confucius are many. His lineal representative has the title of *K'ung* or duke, and large landed property—his by imperial grant; and he is considered to be next in rank to the members of the imperial house. So are the Sage's name and honour perpetuated.

See *Mémoires concernant l'Histoire et les Sciences des Chinois* (Paris, 1776-1814); *Legge's Chinese Classics*, vol. i. (1861), and *Confucius' Life and Teaching* (6th ed. 1887); *Plath's Confucius und Seine Schüler* (1867).

Congé d'élire (Norman-French), the name given in England to the king's warrant or permission to a dean and chapter to proceed to the election of a bishop to a vacant see. Since the act of Henry VIII. in 1534, the *congé d'élire* has always been accompanied by a letter-missive from the sovereign, mentioning the person to be elected by name, so that in reality it is a nomination by the crown. If the dean and chapter delay the election beyond twelve days, the nomination is effected by letters-patent from the crown; if they delay beyond twenty days, or elect another than the person named, they incur the penalties of a *Premunire* (q.v.). See BISHOP.

Conger, or CONGER-EEL, a marine bony fish in the eel family (Muraenidæ). The body is eel-like, without pelvic fins, with a continuous dorsal fin beginning very far forward, and without scales. The length varies from 3 to 6 feet, or even more; the colour is dark gray or bluish above, whitish below; the mouth is wide; the tongue free; the teeth in rows, one closely packed series forming a sharp edge. Four species occur widely distributed in temperate and tropical seas. *Conger vulgaris* is common on the British coasts, especially off Cornwall. Giant specimens, 10 feet in length, 18 inches in girth, over 100 lb. in weight, are recorded; and

even ordinary specimens left aground among the rocks, or landed unexpectedly on board a boat, are awkward customers to deal with. They are very muscular and voracious fishes, feeding on comparatively large prey, and have remarkably strong biting powers. They often rotate rapidly on their

Conger-eel.

own axis, and have a certain degree of grasping power with their tails. The colour seems to vary with habitat, since those from rocks are blacker than those from sand-banks. They occur from the shore down to about 50 fathoms, and are extremely prolific. The flesh is coarse, but is often enough eaten. What is called turtle soup is believed to be often made mainly of conger-eel. See Day's *British Fishes*.

Congestion may be defined to be excess of blood in the vessels of a part, and is to be regarded not as an independent disease, except in a very small proportion of cases, but as one stage or one manifestation of some other disease. It is, however, of such importance and of so frequent occurrence as to require a separate notice. Congestions are divided into two groups—viz. *active*, due to dilatation of the arteries of the affected part; and *passive*, due to some cause interfering with the return of blood by the veins. In active congestion the flow of blood is usually increased, and the excess is chiefly in the arteries. Familiar instances are the phenomenon of Blushing (q.v.) and the effect of heat, especially moist heat, in increasing the redness of any part to which it may be applied. But the most important active congestions are those which occur in connection with inflammation (q.v.), of which they constitute the first stage. In passive congestion the flow of blood is always diminished, and the excess is chiefly in the veins. It may be due either to direct obstruction to the return of blood through the veins, or to general enfeeblement of the circulation.

Congestion from venous obstruction is easily illustrated by tying up the arm, as is done before opening a vein, when the veins are compressed more than the arteries. If the ligature is kept on for a sufficient time, the veins swell, the fingers become red, and then livid, and the whole limb is swollen. Cold applied to the surface of the body acts similarly on it, and contracts the veins more rapidly than the arteries, which lie deeper; and the purple colour of the hands and face after exposure to cold shows the congested state of the capillaries. 'Congestions,' says Dr C. J. B. Williams, 'are caused in internal organs by an obstruction of the veins leading from them. Thus, congestion of the brain may be produced by a tight cravat or by a tumour pressing on the jugular veins. Efforts of straining, coughing, holding the breath, and asthmatic paroxysms which impede the flow of

blood through the lungs, cause congestion in various parts. Tubercles in the lungs cause congestion of that organ. Obstruction to the transit of blood through the liver causes congestion in the abdomen, hemorrhoids, &c.

Congestion from weakness of the circulation includes a numerous class of cases. Here gravitation comes into play very much more forcibly than in the healthy body in determining the distribution of the blood to different parts and organs, though it always produces some effect. Diseases of the valves of the heart are almost always accompanied by congestion of other internal organs at some stage of their progress. In extreme debility, certain fevers, &c., there is general congestion of the parenchymatous organs—the lungs, liver, &c.—and the blood gravitates to the lowest parts, giving rise to what is termed *hypostatic* congestion of the posterior parts of the lungs, the skin of the back, &c. In other cases the effect is more local, as when the feet swell after long standing, in consequence of over-distension of the veins. Congestive affections of this kind are often mistaken for inflammation, and instead of being treated by tonics, are treated by depletion, which, although affording temporary relief, usually aggravates the evil.

Active congestion, when it requires treatment, must be dealt with in the same manner as inflammation. With regard to passive congestion, the end to which treatment must be directed is the removal of its cause. This can be effected in some cases by measures having a local effect, either completely, as by the loosening of a ligature, the disuse of too tight articles of clothing, or by the removal of a tumour compressing veins, or partially, as by elevation of the head in affected brain, and the recumbent position in congestion of the hemorrhoidal or uterine vessels. Uniform gentle pressure, by supporting the weak vessels, and friction, by increasing the onward movement of the blood in the veins, are often of great use in superficial parts. Where the heart-power is at fault, strengthening remedies must be given—*ammonia*, *cinchona bark*, *digitalis*, &c. The *American Witch-hazel* (q.v.) when administered internally seems to have the power of diminishing the size of dilated veins, and is sometimes useful in varicose veins, hemorrhoids, &c. Various remedies are supposed to have a special power of removing the congestion of certain organs; thus, mercurials are recommended for congestion of the liver; *digitalis* and *cantharides* for congestion of the kidneys; *squills*, *benzoin*, and the balsams for bronchial congestion.

Congleton, a market-town and ancient municipal borough in the east of Cheshire, picturesquely situated in a deep valley on the banks of the Dane, an affluent of the Weaver, 26 miles S. of Manchester. It has a handsome town-hall (1864), manufactures of silk, salt-works, and neighbouring coal-mines. Pop. (1851) 11,505; (1881) 11,116.

Conglomerate, or PLUMPUDDING-STONE, a rock consisting of various-sized, round, water-worn stones cemented together, the binding material being generally of a calcareous, siliceous, or ferruginous character. Now and again the stones are held together by simple compression without any cement. Conglomerate is evidently gravel compacted into a more or less coherent mass. Like coarse gravel and shingle, some conglomerates are very tumultuous in appearance, and show no lines or planes of deposition. Generally, however, rocks of this kind exhibit rudely alternating layers of finer and coarser materials. The included stones may consist of any kind of rock or mineral, but the harder species, such as quartz-rock and quartz, are apt to preponderate. Conglomerates are generally

beach-deposits, either marine or lacustrine; sometimes they are of fluvial origin.

Congo. The earlier history of the Congo, the great equatorial river of Central Africa, may be briefly summed up as follows. In the year 1484-85 Diego Cam (q.v.) discovered the mouth of a large river in 7° S. latitude while sailing along the West African coast in command of an expedition having for its object the discovery of the East Indies. He erected a pillar on the south bank, and gave it the name of Rio Padrão, or Pillar River. The country in its vicinity, and for some distance to the south, as far as Cape Negro, was known by the name of Congo Land. During the 15th and 16th centuries several attempts were made by the Portuguese to penetrate into the interior, but they never reached farther than San Salvador. The Jesuits established a large missionary station at this place, and made it the capital of the Congo. At the outset this attempt to convert the nations met with considerable success, but towards the end of the 17th century, ravaged by native wars, it had almost ceased to exist. At this time the Portuguese called the great river the 'Zaire,' which is only a corruption of Nzari, Nzadi, Nyali, Niadi, all of which mean 'river' in the many dialects spoken within the limits of what was then called the kingdom of the Congo. The native name for the river was Moenzi Nzadi, or the 'Receiver of all the Waters;' and the European map-makers give it the name it at present enjoys of 'the Congo.'

In 1816 an expedition under Captain Tuckey was despatched by the British government to solve the question which then agitated the minds of geographers, whether the Congo was one of the mouths of the Niger. Captain Tuckey penetrated with his boats to the head of the navigable portion of the lower river—a distance of 110 miles—and he then proceeded by land to a place called Issangila, about 52 miles farther on; but his expedition had a most melancholy result, for within three months—the period which they remained in the river—eighteen out of fifty-six Europeans succumbed to the climate. This great mortality gave the river a bad name, and, with the exception of slave-traders, it was little frequented by Europeans for some years. Valuable additions to geographical science, however, resulted from Captain Tuckey's expedition, as it proved that the Congo was the outlet of some vast riverine system, and it dispersed much of the fable and myth with which the imaginations of earlier writers had surrounded this region.

From 1867 to 1871 Dr Livingstone, in his researches between Lakes Nyassa and Tanganyika, and from thence to Nyangwe, proved the existence of a large river flowing to the north under the native names of Luapula and Lualaba, which he imagined to be the Nile, and this opinion was shared by many men of science on receipt in England of the maps and journals recording these explorations. In October 1876, five years later, Mr H. M. Stanley, despatched to Central Africa under the auspices of the *New York Herald* and *Daily Telegraph*, to complete Livingstone's explorations, arrived at Nyangwe, and he too gazed on that mighty stream with its waters flowing ceaselessly to the north. He determined to follow its course, and in 1877 news was received of the successful accomplishment of his adventurous journey, and the establishment of the fact that the Luapula, Lualaba, and the Livingstone (the name given by Stanley to that part of the river below Nyangwe) are in reality the Congo—the great equatorial river of Central Africa, the second largest river of the world.

The Lake of Bangweolo noticed by Lacerda in 1795, and by other earlier Portuguese explorers, of

which the Chambezi, traced by Livingstone, is the largest feeder, and into which also flow numerous streams from the Lokinga Mountains on the south, is the reservoir from which this great river issues under the name of the Luapula. Flowing in a northerly direction, it expands into Lake Moero, on leaving which it is called, as far as Nyangwe, the Lualaba; from Nyangwe to Stanley Falls (Arab name for which is Zingatini) Stanley christened it the Livingstone; and from Stanley Falls to the mouth it is known by the name of the Congo.

Its length has been calculated at over 3000 miles; it drains an area of more than 1,300,000 sq. m.; and it discharges a body of water into the ocean second only to the Amazon. Such is the power and force of this mighty stream that no delta exists at its mouth. Vessels take in fresh water at its entrance into the sea, and, during the rainy season, when the river is at its highest, vessels approaching the Congo enter discoloured water, and pass through floating debris more than 300 miles from land. The two largest tributaries of the Congo are the Kassai from the south, whose waters were thoroughly explored (1885) by Lieutenant Wissmann of the German army; and the Mobangi, from the north, explored (1884-85) by the Rev. Mr Grenfell, who penetrated beyond the 4th degree of N. lat., and whose explorations were afterwards continued by Lieutenant Vangele of the Belgian army. This officer reached 21° 53' of E. long., or within about 60 miles of Dr Junker's lowest point on the Makua-Welle, thus proving that the Welle of Schweinfurth is the same as the Mobangi of Grenfell. Besides these two great affluents, the Congo has many other tributaries. The most important of these are the Kwa or Kwango, the Juapa and Bosira, the Ikelemba, the Lulonga, and the Lumami rivers on the south or left bank; and the Aruwimi, the Mbura, the Loika, the Ngala, the Lokinga Nkundji, &c., on the north or right bank.

As regards commerce and navigation, the Congo may be divided into three parts—Lower, Middle, and Upper. The lower region extends from Banana at the mouth to the foot of the first rapids, a distance of 110 miles. Ocean steamers, drawing not more than 18 feet, can safely navigate this portion. The middle or cataract region extends from Vivi to Stanley Pool, a distance of about 235 miles—a portion of this part of the river—viz. from Issangila to Manyanga, a distance of 70 miles, is navigable for small steamers or iron whaleboats. The upper region from Stanley Pool to Stanley Falls has an extent of 1068 miles of navigable water for steamers of a draught not exceeding four feet. The length of navigable tributaries which enter in this section of the river has been calculated at over 3000 miles, forming a unique system of waterways.

These discoveries by Mr Stanley led, in 1878, to the formation of the Association Internationale under His Majesty the King of the Belgians, and this subsequently expanded into the Congo Free State, which, recognised by the European powers assembled at the conference at Berlin in the year 1885, has the following boundaries: The northern bank from the mouth, with a strip of territory averaging about 60 miles in width, as far as Manyanga, situated about 240 miles from Banana, the entrance part of the river. At Manyanga the French territory commences and continues along the north bank, passing Stanley Pool as far as the Mobangi. The territory of the Congo Free State recommences at this river, and the boundary line runs along the left bank as far as the fourth parallel of N. latitude, which then becomes the northern boundary of the central portion of the state.

The southern boundary line commences on the river Congo at Wango-Wango, about 100 miles from its mouth, from thence it runs along the parallel of Nokki till it meets the river Kwa, after which it follows the 6th parallel of S. latitude. Its eastern boundary is not accurately defined, but it is supposed to follow the watershed of the Nile and Congo to the north-east, and to comprise, on the south-east, the basin of the Congo where it does not conflict with previous interests.

The Congo Free State is governed by an administrative bureau at Brussels, consisting of three secretariats—Control, Finance, and Foreign Affairs, under the direct supervision of His Majesty the King of the Belgians; also by an administrator on the Congo who has his headquarters at Boma, 60 miles from the sea, on the right bank of the river. The state has stations at Banana, Vivi, Boma, and Matadi on the Lower Congo; at Lukungu, Issangila, Manyanga, Lutete on the Middle Congo; and at Leopoldville, Kinshassa, Kwamouth, Lukolela, Equator, Bangala, and Stanley Falls on the Upper Congo. Besides these the state has erected two stations on the Kasai, Luebo, and Luluaberg. All imports are free, and only such export duties are levied as are necessary to carry on the work of administration. It has a coinage and postal service, and has entered into the Postal Union. A road has been surveyed between Matadi and Leopoldville, and by the introduction of ox-wagons the facilities for transport will be largely increased. It is intended to follow this up by a railway. Its present income is derived from an endowment of £40,000 a year bestowed upon it by His Majesty the King of the Belgians, and such other sums as are produced by its export dues.

The inhabitants of the Congo basin belong to what has been termed the Bantu race. They are a happy, inoffensive people, not so dark as the Fan or Ethiopian. Split up into numberless tribal communities, they can offer but slight resistance to the advance of civilisation; and as they are born traders, they take very readily to commerce. The dialects throughout the country are very numerous, but many of them would appear to have a common origin (see BANTU). Even the Swaheli language, spoken by the natives of Zanzibar (who come as porters, &c. into this region), has much in common with the Kishi Congo, or language spoken on the west coast. Of this typical member of the Bantu family, the Rev. W. Holman Bentley has furnished an excellent *Dictionary and Grammar* (Lond. 1888). The religion is mainly fetishism; and domestic slavery exists everywhere. This must not be confounded with the slave-trade of the Arabs, and presents none of the revolting cruelties which have aroused the indignation of the civilised world.

Much has been said and written about the climate. It is purely tropical, the average temperature ranging between 78° and 82°. Malarial fevers, especially on the coast, are not infrequent; but with care and attention to diet Europeans can remain in the country for several years without change. The interior has been found to be more healthy than on the coast.

The principal products are ivory, palm-oil, palm-kernels, india-rubber, various gums, ground-nuts, camwood, beeswax, orchilla, &c. The country, however, is still undeveloped. Wild coffee, tobacco, and hill rice are cultivated on the upper river, also various kinds of maize and sorghum. Tropical fruits, such as bananas, pine-apples, and mangos, abound. The total value of the special exports (principally ivory and palm-oil and kernels) from the Congo in 1887 was returned at £79,218, and of the general exports at £306,720. No minerals of importance have as yet been discovered.

The population of the state has been variously estimated at from twenty to forty millions of people, but to arrive at any correct deductions on this point with our present data is impossible.

History has shown that the introduction of civilisation into new and wild countries demands time and patience. The advance that has been made by the Congo Free State has been exceptionally rapid, and from the great natural and physical advantages it possesses, as well as from the peaceful nature and trading qualities of its inhabitants, it will no doubt become, under its present enlightened ruler, the most important state in Central Africa. See map of Africa in Vol. I., and the articles AFRICA, STANLEY; also Stanley, *Through the Dark Continent* (1878), and *The Congo and the Founding of its Free State* (1885); H. H. Johnston, *The River Congo from its mouth to Bolobo* (1884); Bentley, *Life on the Congo* (1887); Coquilhat, *Sur le Haut Congo* (1888).

Congo Snake. See AMPHUMA.

Congregation (Lat. *con*, 'together'; *grex*, 'a flock'), an assembly, generally a religious assembly; in its most ordinary use, an assembly of Christians met in one place for worship (see CHURCH).—In the Roman Catholic Church, it often designates a sort of board of cardinals, prelates, and divines, to which is intrusted the management of some important branch of the affairs of the church. Thus the *Congregation of the Index* examines books and decides on their fitness for general perusal (see INDEX). The *Congregation de Propaganda Fide* is instituted for the propagation of the Roman Catholic faith and the government of the church in non-Catholic countries (see PROPAGANDA). The *Congregation of Relics* inquires into the genuineness of supposed relics. The *Congregation of the Holy Office* takes cognisance of heresies, &c. (see INQUISITION). The *Congregation of Rites* regulates the festivals and offices of new saints. There are numerous other congregations. The word is also used in the Church of Rome to describe communities of ecclesiastics who live together under rule, but without being bound by vow, or at least by solemn vow. Such are the *Congregation of the Oratory*, the *Congregation of the most Holy Redeemer*, usually called Redemptorists, &c.

Congregationalists. See INDEPENDENTS.

Congress, an assembly either of sovereign princes, or of the delegated representatives of sovereign states, for the purpose of considering matters of international interest. Even in America, though the term has now a different meaning, it had a similar origin, the first congress being that of the delegates from the various British colonies, who met on the 7th October 1765, for the purpose of considering their grievances. Previous to signing a treaty of peace, a meeting of plenipotentiaries usually takes place, to which the name of a congress is sometimes applied, though it seems more properly to be reserved for those more important meetings at which extensive schemes of future policy are determined on, and the balance of power amongst the various European states readjusted. To this class belonged the famous Congress of Vienna in 1815; that of Carlsbad in 1819, for settling the affairs of Germany; that of Paris in 1814 and 1815, at the end of the Russian war of 1814-15; and that of Berlin after the Russo-Turkish war of 1877-78. There is scarcely any difference between a congress and a diplomatic Conference (q.v.).

Congress of the United States. The name of the United States is called the Congress of the United States, and is elected by the several states, and Representatives, elected by the

direct votes of the people. It is supreme within its constitutional limits, deriving its powers directly from the people. By constitutional provision congress has certain direct, express powers, and such implied powers as are necessary to carry these into effect. It convenes on the first Monday in December in each year, and receives from the president of the United States his annual message, giving information of the state of the Union, and containing such suggestions and recommendations as he may judge expedient and necessary.

Express Powers.—Congress has power to impose and collect taxes, duties, imports, and excises, to pay the debts and provide for the common defence and general welfare of the United States. This grant of sovereign power is independent of state control, and is limited only by the provision in the constitution that the duties, imports, and excises shall be uniform throughout the United States.

Congress has power to borrow money on the credit of the United States, to regulate commerce with foreign nations, and among the several states and with the Indian tribes. It has the exclusive power to establish a uniform rule of naturalisation, and uniform laws on the subject of bankruptcies throughout the United States; to coin money, regulate the value thereof and of foreign coin, and fix the standard of weights and measures; to provide for the punishment of counterfeiting the securities and current coin of the United States; and to establish post-offices and post-roads. Congress has power to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries; to constitute tribunals inferior to the Supreme Court; to define and punish piracies and felonies committed on the high seas, and offences against the law of nations.

Congress alone has power to declare war, grant letters of marque and reprisal, and make rules concerning captures on land and water. It can raise and support armies, may provide and maintain a navy, and make rules for the government of the land and naval forces. Congress has power to provide for calling forth the militia of the several states for the purpose of executing the United States laws, to suppress insurrections, and repel invasions, and to provide for organising, arming, and disciplining the militia, and for governing such part of them as may be employed in the service of the United States; reserving to the states respectively the appointment of the officers, and the authority of training the militia, according to the discipline prescribed by congress.

Congress exercises exclusive legislative control in all cases whatsoever over the District of Columbia (the seat of government of the United States), and over all places purchased for the erection of forts, magazines, arsenals, dockyards, and other needful buildings. Congress has power to dispose of and make all needful rules and regulations respecting the territory or other property belonging to the United States, and to make all laws which shall be necessary and proper for carrying into execution all powers vested by the constitution in the government of the United States, or in any department or offices thereof.

Constitutional Limitations.—Congress cannot pass a bill of attainder or any *ex post facto* law. Neither can it lay any tax or duty upon articles exported from any state, or give preference to the ports of one state over those of another, by any regulation of commerce or revenue; nor can it compel vessels bound to or from one state to enter, clear, or pay duties in another. It cannot enact a law taking from the citizen his private property for public use without compensation therefor.

Congress cannot make any law respecting an

establishment of religion, or prohibiting the free exercise thereof, or abridging the freedom of speech or of the press, or denying the right of the people peaceably to assemble, and to petition the government for a redress of grievances. Congress cannot enact any law that will render the people insecure in their persons, houses, papers, and effects from unreasonable searches and seizures; or authorise any warrants to issue but upon probable cause supported by oath or affirmation, particularly describing the place to be searched, and the persons or things to be seized. Congress has no power to take from a person accused of crime his right to a speedy and public trial, by an impartial jury of the state or district wherein the crime was committed; or his right to be informed of the nature and cause of the accusation, to be confronted with the witnesses against him, and to have compulsory process for obtaining witnesses in his favour; or his right to be defended by counsel. It cannot enact a law requiring excessive bail, imposing excessive fines, or inflicting cruel and unusual punishments.

Senate.—The senate is composed of two senators from each state, chosen by the legislature thereof for a term of six years, so arranged that one-third of all the senators shall go out every two years. No person is eligible for the office of senator unless he is thirty years of age, has been a citizen of the United States nine years, and is an inhabitant of the state for which he is chosen. The senate is presided over by the vice-president of the United States, but in case that officer is acting president of the United States, or is unable to preside, the senate elects a presiding officer *pro tempore*. It chooses all its other officers. The senate has the sole power to try impeachments presented by the House of Representatives, and when sitting in that capacity the senators are sworn or affirmed. Should the president of the United States be on trial, the chief-justice of the Supreme Court of the United States presides, and two-thirds of the senate may convict, upon which judgment of removal from office and disqualification to hold any office of honour, trust, or profit under the United States may be pronounced.

House of Representatives.—The House of Representatives is composed of members chosen every second year by the people of the several states. It elects a Speaker to preside over its deliberations, and all its other officers. No person can be a representative in congress who has not attained the age of twenty-five years and been seven years a citizen of the United States, and he must be an inhabitant of the state in which he is chosen.

The representatives are apportioned among the several states according to the number of their inhabitants respectively, counting the whole number of persons in each state, excluding Indians not taxed. But when the right to vote at any election for the choice of electors for president and vice-president of the United States, representatives in congress, the executive and judicial officers of a state, or the members of the legislature thereof, is denied to any of the male inhabitants of such state, being twenty-one years of age and citizens of the United States, or is in any way abridged, except for participation in rebellion or other crime, by constitutional provision the basis of representation is reduced in the proportion which the number of such male citizens bears to the whole number of male citizens twenty-one years of age in such state. The first article of the United States Constitution provides that there shall not be more than one representative to every 30,000 inhabitants, but the apportionment made February 25, 1882, after the tenth census, gave in 1888 one representative to every 150,000 inhabitants, or 325 in all. Each

organised territory of the United States is entitled to send one delegate to the House of Representatives, who may take part in the debates but cannot vote.

The House of Representatives has the sole power of impeachment of the executive and judicial officers of the United States, and must present the charges on which it rests to the senate for trial. Each house is judge of the elections, returns, and qualifications of its own members, and a majority constitute a quorum to do business; but a less number may adjourn from day to day, and may be authorised to compel the attendance of absent members.

Each house determines the rules of its own procedure, and may punish its members for disorderly behaviour, and also may compel the attendance of witnesses before its committees, and inflict punishment for contempt of its authority.

Each house must keep a journal of its proceedings, and must publish the same (excepting such parts as may in their judgment require secrecy), and at the desire of one-fifth of the members present, the yeas and nays of the members voting on any question must be entered on the journal. But neither house, during the session of congress, without the consent of the other, can adjourn for more than three days, nor to any other place than that in which the two houses shall be sitting.

No senator or representative may be appointed to any civil office under the authority of the United States which shall have been created during the time for which he was elected, and no person holding any office under the United States can, during his continuance in office, be a member of either house of congress.

Members of congress are privileged from arrest, except for treason, felony, and breach of the peace, during their attendance upon their public duties.

Two-thirds of the senators present must concur in any treaty which may be made, and in all appointments by the president of ambassadors, or other public ministers and consuls, judges of the Supreme Court of the United States, and such other officers whose appointments are not otherwise provided for.

By the amendments to the Constitution of the United States, abolishing slavery, guaranteeing civil rights, the validity of the public debt of the United States, and forbidding the denial or abridgment of the United States citizen's right to vote on account of race, colour, or previous condition of servitude, congress is empowered to enforce these provisions by appropriate legislation.

When any person, having taken an oath to support the constitution of the United States, as an executive or judicial officer of the United States or of any state, or as a member of congress or state legislature, is, by article xiv. of the United States constitution, ineligible to the position of senator or representative, or elector of president and vice-president of the United States, or to any office, civil or military, under the government of the United States, from having engaged in insurrection or rebellion against the same, congress is empowered to remove this disability by a two-thirds vote of both houses.

ACTS OF CONGRESS are the legislative enactments of the two houses of congress. Bills may originate in either house (except bills for raising revenue, which must originate in the House of Representatives), and be introduced by any member, and may be amended in either house. They are usually referred to the appropriate standing committee for examination and report; and are read a first, second, and third time before being put upon their final passage, being subject to modification or amendment and discussion, according to the rules in each house.

After a bill has been passed by both houses, it is presented to the president of the United States for his approval and signature. If he approves and signs it, it becomes a law. If he does not approve it, the president returns it, with his objections, to the house in which it originated; and that house must enter his objections at large upon its journal, and proceed to reconsider it. If after reconsideration it is passed by a two-thirds vote, it is sent to the other house with the president's objections, by which it shall likewise be reconsidered, and if approved by two-thirds of that house, it becomes a law; the vote in both houses must be taken by yeas and nays, and the names of the voters for or against are entered upon the journal of each house respectively. If the bill is not returned by the president within ten days (Sundays excepted), it becomes a law in the same manner as if he had signed it, unless congress by adjournment prevents its return, in which case it does not become a law.

Every order, resolution, or vote to which the concurrence of both houses is necessary (except adjournment) must likewise be presented to the president after passage, and in case of his disapproval (or veto) must be repassed by a two-thirds vote in the same manner as bills, in order to become a law notwithstanding his objections.

The sessions of congress usually continue during several months, but congress can adjourn at any time by the concurrence of a majority of both houses. If, however, congress adjourns without passing the appropriation bills necessary for the expenses of government, or in other emergencies, a special session of congress may be called by the president of the United States. Each congress ends on the fourth day of March, every second year, at 12 o'clock noon.

Congreve, RICHARD, Positivist, was born September 4, 1818, and educated under Arnold at Rugby, passing afterwards to Wadham College, Oxford, of which he became successively scholar, fellow, and tutor, but resigned after having become definitively a disciple of Comte. In 1855 he published a good edition of Aristotle's *Politics*. Later works are *Lectures on the Roman Empire of the West* (1855); *Elizabeth of England* (1862); *The Catechism of Positivist Religion* (1858); *Essays: Political, Social, and Religious* (1874); besides many propagandist sermons and addresses.

Congreve, WILLIAM, the greatest master of the English comedy of repartee, as distinguished from the humoristic or Jonsonian comedy which it replaced, was born at Bardsey, near Leeds, and baptised on February 10, 1669 (1670). As a school-boy he was educated at Kilkenny, and as an undergraduate at Trinity College, Dublin. And if this does really make an English gentleman an Irish one, as certain writers learned in 'racial mixings' have generously assumed, Congreve's genius may be taken as another proof that English wit, like English poetry, is the outcome of that mysterious 'Celtic element,' or breath of the 'Celtic Titan' discovered by the late Matthew Arnold. After the completion of his education, Congreve returned to England, and began life in London, where, like Wycherley, and, indeed, like many another man of letters, he entered upon the study of the law—an arid study, as is generally supposed, for a wit, and yet one which (being the study of the practical logic of life) does more than any other, it has been said, to solidify and strengthen the disparate forces of the intellect in whatsoever field those forces may afterwards come to be exercised. Entered at the Middle Temple, but finding, as Leigh Hunt says, that 'having family as well as wit and scholarship,' he could 'make way in life without a profession,' Congreve invaded very early the literary arena

where 'family and wit and scholarship' were in those old days of more account than would now seem possible. His first publication was *Incognita, or Love and Duty Reconciled*, a novel of cross-purposes and disguises, based partly on reminiscences of the method of Shakespeare's fancy-plays, and partly on reminiscences of a very different dramatic method, that of the new prose comedy which, invented by Etherege, had been very greatly strengthened by Wycherley. When Dr Johnson said of this novel that he 'would rather praise it than read it,' he spoke with his usual sagacity—indeed, he may be said to have marked out a course of criticism which has found high favour among succeeding critics of fiction—a course which is, no doubt, as wise as amiable in regard to nine novels out of any given ten. But whether the tenth, the novel to be read as well as praised, should properly be *Rasselas* or *Incognita* seems to depend, now as then, on the temper and the constitution of the praiser. If *Rasselas* is the more instructive, *Incognita* is the more amusing. For though to laugh with the author is difficult, to laugh at him is easy enough, and laughter is certainly good. Congreve's novel is rich in 'cultismo' of that highly ornate kind which has at intervals illuminated modern literature from Gongora to Dr Chivers. Such a passage as that in which Congreve talks about his heroine's employing one of Cupid's pen-feathers 'to pick her teeth' would have satisfied even such masters of style as the author of *Polyphemus* and the author of *Eonchs of Ruby*.

That a story so full of that silly mock-sentiment then in vogue—stuff which would now make even school-girls laugh—should have been written by the great wit and humorist of *Love for Love*—that the story should have had a very great success among those same cynical beaux and brazen belles who were in the habit of sitting out *She Would if She Could* and the *Country Wife*—would be incredible did we not remember the still more astonishing fact that the love-passion—the passion which Shakespeare and Ford and the rest of the Shakespearians had delineated so powerfully—was, judging from the literature of Congreve's time, wiped out as by a sponge from the English character. It is not enough to say that as soon as the wits of the coffee-houses attempted to touch the love-passion their sense of humour straightway fled: their common sense fled too; they became idiots, positive idiots. As far as date of publication goes, Congreve's novel was followed by his translation of the eleventh satire of Juvenal. This appeared in Dryden's *Juvenal and Persius*, dated 1693, but actually published in 1692. From Dryden, to whom he had been introduced it is said by Southorne, Congreve received unvarying kindness—kindness which was answered by unvarying gratitude, or rather by that generosity of recognition among fine spirits—the sublimation of gratitude—which is said to be undreamed of by smaller souls. In January 1693 appeared Congreve's comedy the *Old Bachelor*, under the auspices of Dryden—'then as now a living and immortal witness to the falsehood of the vulgar charge which taxes the greater among the poets with jealousy or envy, the natural badge and brand of the smallest that would claim a place among their kind.' But if Dryden was free from envy, the disease which, according to the above skilful diagnosis by Mr Swinburne, afflicts poetasters and criticasters alone, not less free from this literary leprosy was Congreve himself. This is what makes him, notwithstanding his rank-worship, so interesting as a personality; this is what also makes the other comic dramatists Etherege and Vanbrugh interesting, so interesting, that we would fain, if we dared, condone even such sins against the sanctities of art as theirs; they

were free from the disease which it seems feeds the lower slopes of Parnassus with poisonous air. No three writers were ever more generally beloved—none were ever beloved more deservedly than these. And even Wycherley—he whose literary sins were the most grievous of all—was, on account of his fine social qualities, called 'Manly Wycherley.' That a corrupt court should have spoiled such men as these is, among all the heavy impeachments of the Restoration, the heaviest.

Congreve's freedom from the fussy egotism of the litterateur served him in good stead in regard to the *Old Bachelor*. Dryden, while declaring that he 'never saw such a first play in his life,' hinted at the same time that a great deal of skilful manipulation was required before it could be safely placed upon the boards. And he and Southerne and Maynwaring, who set about manipulating it, seem to have had from Congreve *carte blanche* to do with it as they liked. The brilliant success of the *Old Bachelor*—a play whose merits were of entirely a literary kind—is evidence of the enormous change that has come over play-goers since those days. Congreve's second comedy, the *Double Dealer*, which appeared in the November of 1693, was more firmly knit, and in every way stronger than the *Old Bachelor*, but the satire on the morals of the time—especially on the meanness and heartless treachery in sexual relations which had become the fashion of the court, was administered in too serious a temper to please an audience composed largely of the very people satirised. The empty-headed beaux and callous women who went to the theatre went there to be amused, not to be sermonised. But besides this repellent quality, the play suffered from a want of dramatic illusion greater in a certain sense than even the *Old Bachelor* had displayed. An audience can scarcely be interested in the doings of a villain who every few minutes comes to the footlights in order to assure them what a consummate villain he is, and on what admirable psychological principles his creator has fashioned him, nor yet in a hero who lets a villain do what he will in order that the dramatist's plot may be conveniently worked out. In stage-craft Congreve was always weaker than Vanbrugh and Wycherley, but the weakness made itself specially conspicuous here.

It was to this play that was prefixed Dryden's famous verses 'To my dear friend, Mr Congreve,' verses whose generosity passes into pathos. Congreve's next publication was the *Mourning Muse of Alexis*, a poetic dialogue upon the subject of Queen Mary's death, as full of artificial conceits as his novel. *Love for Love*, the finest prose comedy in the English language, finished in 1694, was produced at the 'theatre in Little Lincoln's Inn Fields' in 1695. It has an abandonment of humour, an irresistible rush of sparkling merriment, such as Congreve's previous plays had not promised. In judging of its qualities we must not forget that in comedy as in tragedy—in prose as in verse—nothing is really informed by artistic vitality which lacks the rhythmic rush born of creative enjoyment. To him who is really and truly organised to write, whether in verse or in prose, there is always in the genuine exercise of his faculty a sense of sport as delightful as it is deep, an exhilaration that cannot be simulated and that cannot be supplied to the nervous system of the true writing man by any other stimulant. Not all the *Paradis artificiels* summoned up by the geni of Opium, Hashish, or Alcohol, can compete with the true paradise which the Genius of the Inkhorn throws open to the born litterateur when the impulse is really upon him. And as surely as the hilarity of artistic creation is seen in Aristophanes, in Lucian, in Rabelais, in Shakespeare, in Swift, in Dickens, is it seen in Congreve's *Love for Love*. No wonder then that of

all his plays it was the last to be banished from the stage. So late as 1842 Macready revived it (modified of course) at Drury Lane, and this was followed by still later revivals, the last of all being a version of the play in three acts, compressed by Mr John Hollingshead at the Gaiety Theatre in November 1871, with Miss Cavendish in Angelica and Miss Farren in Prue. In *Love for Love* culminated the prose comedy of England. Abundant and brilliant as is the wit, the coruscations do not, as in Congreve's other plays, outdazzle the sweeter and softer light of the humour. The characterisation is true, true under the conditions which, as he himself admirably said in his letter to Dennis, the comedian must always work under. 'The distance of the stage,' says he, 'requires the figure represented to be something better than the life; and, sure, a picture may have features larger in proportion and yet be very like the original. If this exactness of quantity were to be observed in wit, as some would have it in humour, what would become of those characters that are designed for men of wit? I believe, if a poet should steal a dialogue of any length from the extempore discourse of the two wittiest men upon earth, he would find the scene but coldly received by the town.'

Some of the characterisation, such as that of Angelica, is really beautiful, while some, like that of Sir Sampson Legend, in its genial breadth passes from the comedy of artifice into absolute comedy, and is almost Shakespearian. In 1697 Congreve's one tragedy, the *Mourning Bride*, appeared. The honours it received in the last century were as excessive as the contempt it has met with in this. No doubt it is full of improbabilities, but it shows a considerable power of invention of melodramatic if not of tragic incident. The purely theatric and scenic qualities of the second act are of a most original, if not of high order, and with the scenic appliances of our own day might be made theatrically effective. Of course, however, it is cold—cold as those 'monumental caves of death' which 'shot a chillness' to the 'trembling hearts' of Drs Johnson and Blackmore—and nothing could really warm it.

Between the date of the *Mourning Bride* and that of Congreve's last comedy, the *Way of the World*, he was busily occupied, in company with several others, in the famous Jeremy Collier controversy, defending the morality of the new stage. The great mistake of Congreve's life was this—of defending his plays on moral grounds. To 'let well alone' is wise: to let ill alone is perhaps wiser still. Of all sins, that of producing harmful literature is the blackest. It is the peculiar glory of letters that stronger than king or kaiser is he who writes strongly. It is so to-day: it was so when the warrior kings of Nineveh went out to reap glory—i.e., to slay and flay—in order to furnish the scribe with subjects—in order that the scribe should, in bas-relief and cuneiform character, record their doings. Hence, in the truest and deepest sense, to write is, as Bishop Butler has said, to act; and if, as he declares, 'endeavouring to force upon our minds a practical sense of virtue, or to beget in others that practical sense of it which a man really has himself, is a virtuous act,' what, on the other hand, was the act of him who wrote certain scenes in the *Double Dealer* and *Love for Love*?

And yet even this new stage was not without one saving grace till Congreve defended it; it had a frankness in sin: that was something at least. Its place was not alongside those filthily French fictions of our own time which, while pandering to the bestial side of man, set up an impudent pretence of doing so for the good of his soul. But Congreve in his lame defence condescended to

the part of the hypocrite—condescended to exploit Aristotle's paradox about comedy being an imitation of bad characters—an imitation with an ethical end; as if such comedy as his had anything to do with ethical ends! Notwithstanding the conventional tags at the end of Congreve's plays—tags which had no serious meaning, and were meant to have none—the 'Seventh Hell' of the Hypocrite could never claim the author of *Love for Love* until he set about defending that play. Better to leave ill alone, we say.

Congreve's last play, the *Way of the World*, was produced in 1700. Though quite as full of intellectual brilliance as *Love for Love*, and evidently written with more care, not to say labour, it lacks the humorous impulse which we have seen in Congreve's masterpiece. The glitter is that of icicles in the sunlight. The wit of the dialogue is not sufficiently held in hand to work out the characters and the plot. In a word, it comes more completely than does any other of Congreve's plays within the scope of the Duke of Buckinghamshire's strictures upon the comedy of repartee:

Another fault, which often does befall,
Is when the wit of some great poet shall
So overflow, that is, be none at all,
That ev'n his fools speak sense, as if possess'd,
And each by inspiration breaks his jest,
If once the justness of each part be lost,
Well may we laugh, but at the poet's cost.

This play was received with comparative coldness, and Congreve wrote no more for the stage; but he lived till January 1729. Socially his life was one unbroken success. Physical suffering he had, but most of it was the result perhaps of his own youthful indiscretions. Kneller's portrait shows him to have been a handsome man with dark eyes. His career shows him to have been a man of fine genius who, smitten with the English canker of rank-worship, succeeded in half-misprising his endowments and living and dying genteel. He amassed a fortune, and left it not to his greatest friend Mrs Bracegirdle, a woman of genius, of surpassing beauty, and most lovable nature, who had sacrificed everything for him, but to the Duchess of Marlborough, who, after his death, had a waxen statue of him made—a statue which sat at her table in his very clothes, and nodded mechanically over the dinner at Her Grace's smallest joke, even as he had used to nod in the flesh. Socially, we say his life was one unbroken success; and in his death he and gentility were not divided.

Congreve, SIR WILLIAM, inventor of the Congreve rocket, was born 20th May 1772, the eldest son of William Congreve, Comptroller of the Royal Laboratory at Woolwich, created a baronet in 1812. Young Congreve passed through the Royal Academy at Woolwich, and in 1808, after a long series of experiments, contrived the Congreve rocket. It was tried in the Basque roads in 1809, and at Leipzig in 1813, scarcely with the success that was expected. Honours were heaped on Congreve; he was elected F.R.S., and returned to parliament in 1812. Two years later he succeeded to the baronetcy and his father's place. He died at Toulouse, 16th May 1828. See **ROCKET**.

Coni, or CUNEO, capital of an Italian province, stands in a fruitful district, 48 miles SW. of Turin by rail. It has a fine cathedral, lately restored. It was once strongly fortified, and a place of great strategic importance. Its chief manufactures are silk, cotton, and paper. Pop. (1881) 12,413.

Coniferae. This important and interesting order of dicotyledons attained its maximum importance during past geological periods; its world-wide

geographical distribution and strongly marked family and generic differences being in this way explained—i.e. when we regard the existing forms as the survivors of a larger and once predominant coniferous flora, which has been in good part displaced by the more recent and higher monocotyledonous and dicotyledonous (angiospermous) forms. About 300 species, included in about 33 genera, now remain. Leaving the questions of floral morphology and minute structure which separate the conifers (along with Cycads and Gnetaceae) from the remaining phanerogams or 'angiosperms' to the article **GYMNOSPERMS**, it may be most profitable here to make a rapid survey of the most important groups of the order, with their principal types. Various systems of classification have been propounded; an old and widely adopted one recognises three sub-orders, the pines (*Abietineae*), cypresses (*Cupressineae*), and yews (*Taxineae*). Since, however, the first two of these are much less widely separated from each other than from the third, later systematists are returning to the classification of Lindley, and regard these as making up a single sub-order (*Pinoideae*) equivalent to the yew (*Taxoideae*). On account of the exceptional importance of this order, alike in forestry and horticulture, a brief enumeration of the families of these sub-orders, with mention of their most important species, may now be given.

Commencing with the *Abietineae* division of *Pinoideae*, we find three families, the pines proper (*Abietinae*), *Araucarias* (*Araucariinae*), and *Taxodiums* (*Taxodiinae*). The genus *Abies* (including *Picea*) consists of evergreen trees, or sometimes shrubs, in which the linear and always more or less completely needle-shaped leaves arise singly, and are never clustered in branchlets, while the scales of the cones are not thickened at the tip. The list may be headed by the Spruce Fir, or Norway Spruce (*A. excelsa*), one of our commonest trees, while *A. Douglasii*, *A. nobilis*, and other Californian species are of special beauty as trees and value as timber, with other species too numerous to mention. The old Linnean genus *Pinus* (from which the firs, larches, and cedars have been separated off as *Abies*, *Larix*, and *Cedrus* respectively) still includes about 100 species, easily distinguished from *Abies* by the grouping of the leaves upon arrested branchlets, the thickening of the tips of the cone-scales, and other characters. Among the more important species, *P. sylvestris* (the Scotch fir), *P. austriaca* (the Austrian pine), *P. Laricio* (the Corsican pine), *P. Pinaster* (the cluster pine), and *P. Pinea* (the stone pine of southern Europe), may be first mentioned, alike on account of their frequency of occurrence in forests and plantations in Europe, and as agreeing in having usually only two leaves on each branchlet. A large and chiefly Californian series agrees in having three leaves on each sheath. Of these, *P. insignis* (the Oregon pitch pine), *P. Benthamiana*, and *P. radiata* may be mentioned; finally a series, usually five-leaved, includes the Weymouth Pine and White Pine of North-east America (*P. Strobus*), the Siberian Stone Pine (*P. Cembra*), &c. Of the allied genus *Larix* (see **LARCH**) only *L. europaea* (*decidua*) need here be mentioned, while of *Cedrus* (see **CEDAR**) *C. Libanus* and *C. Deodora* are of special importance. The *Araucariinae* are familiarly represented by the *A. imbricatu* of Chili, so common in suburban gardens (see **ARAUCARIA**), and other more graceful but usually less hardy species; as also by the important Kauri pine and other species of *Dammara* (q.v.).

The *Taxodiinae* include a number of very important trees, notably the curious umbrella pine (*Sciadopitys*) of Japan, *Cunninghamia sinensis* of China, and the colossal *Sequoia* (*Wellingtonia gigantea*)

of California, with its allied species (see *SEQUOIA*). In addition to these we may mention also the Japanese Cedar (*Cryptomeria japonica*, the Virginian Bald Cypress (*Taxodium distichum*).

Among the Cupressineæ we have first the cypresses proper, which includes besides the well-known genus *Cupressus* (see *CYPRESS*) the closely allied *Retinospora* of Japan. *Juniperus* (see *JUNIPER*) alone forms another sub-family; while *Thuja* (see *ARBOR VITÆ*) with its immediate allies *Thujopsis* and *Libocedrus* constitute a third; and *Callitris* with *Actinostrobus* and *Fitzroya* make up the fourth.

Passing now to the sub-order of yews (*Taxoideæ*) we have again two main divisions, the yews proper or *Taxee*, and the *Podocarpæ*. Among the latter we shall only mention the oriental genus *Podocarpus*, and the beautiful *Dacrydium cupressinum* of New Zealand; but the former are of much greater variety and importance (see *YEW*). Besides the species of *Taxus*, we have especially the Chinese and Japanese *Cephalotaxus*, the curious *Ginkgo* (*Salsburia*) *adiantifolia* of the same region, together with the Chinese and Californian species of *Torreya*.

In addition to the general article *GYMNOSPERMS*, and to those devoted to particular genera or species of conifers, the reader should especially consult Engler's *Pflanzenfamilien*, both for a full summary of our present knowledge and copious references. For the purposes of the English horticulturist Veitch's *Manual of Conifers* is most exhaustive, while Gordon's *Pinctum*, and Hemsley's *Handbook of Hardy Trees*, &c. (Lond. 1877), will be found of service to the amateur.

Conington, JOHN, a great classical scholar, was born at Boston, 10th August 1825. He was educated at Beverley, and for five years at Rugby, obtained a demyship at Magdalen College, Oxford, in 1843, and next year carried off, in the same term, the Hertford and Ireland scholarships. In 1846 he betook himself to University College, where he was elected to a fellowship two years later. Other distinctions he won were the chancellor's prize for Latin verse, for an English essay, and for a Latin essay. Determining not to take orders, he tried the study of law, but soon abandoned it in disgust. In 1854 he was appointed to the newly-founded chair of Latin Language and Literature at Oxford, which he filled until his untimely death at his native place, October 23, 1869. The impulse that Conington's lofty and contagious enthusiasm gave to classical scholarship and real culture in England was far more considerable than anything he was able to effect in the way of performance. His unique personality and the singular charm of his simple but serious nature made a profound and permanent impression upon his friends and pupils. His greatest work is his edition of *Virgil* (3 vols. 1861-68), with its singularly subtle and suggestive essays. His edition of the *Agamemnon* (1848) and *Choephori* (1857) of *Æschylus* are of less moment, though indeed the latter is admirable. In his last years he gave himself much to translation, the results of which were his metrical version of the *Odes* of Horace (1863); the *Æneid* (1866), in Scott's ballad-metre; the *Iliad* (1868), in the Spenserian stanza; and the *Satires* and *Epistles* of Horace (1869), in the couplet of Pope. Of these the last is without doubt the most valuable. His edition of *Persius* was published in 1872, and in the same year his *Miscellaneous Writings* (2 vols.), with a short Life by Professor H. J. S. Smith.

Coniostres, a term often applied to a section of Passerine birds, characterised by a strong conical beak. It includes numerous families, and such types as weaver-birds, finches, sparrows, and larks.

The character referred to is too external and adaptive to be of much importance, and the term is too wide in its application to be of much use. It is better disused.

Coniston Grits and Flags, a series of siliceous sandstones, grits, flags, and conglomerates, belonging to the Silurian system of Cumberland, &c. They take their name from Coniston in Lancashire, and attain a maximum thickness of probably not less than 7000 feet. They are characterised—the finer grained beds (flags) especially—by the presence of many species of graptolites and other fossils. They are believed to be on the same geological horizon as the Denbighshire grits and flags of Wales. See *SILURIAN SYSTEM*.

Coniston Lake, in the English Lake District, lies in North Lancashire, at the east foot of the Coniston Fells, 9 miles W. of Bowness on Windermere, and 10 by rail NNE. of Foxfield Junction. It is 5 miles long, $\frac{1}{2}$ mile broad, 147 feet above the sea, and its greatest depth is 260 feet. Its waters abound with trout and perch. On the east shore stand Ruskin's home, Brantwood, and Tent House, once Tennyson's residence. The Old Man of Coniston, to the north-west, is 2633 feet high.

Conium. See *HEMLOCK*.

Conjugal Rights. See *MARRIAGE*.

Conjugation, a term in Grammar applied to a connected view or statement of the inflectional changes of form that a verb undergoes in its various relations. See the articles *GRAMMAR* and *INFLECTION*.

Conjugation of Cells, a mode of reproduction in which two apparently similar cells unite, as in *Amoeba*, *Diatoms*, *Spirogyra*, &c. See *ALGÆ*, *DESMIIDS*, *DIATOMS*, and *REPRODUCTION*.

Conjunction, in Astronomy, is one of the Aspects (q.v.) of the planets. Two heavenly bodies are in conjunction when they have the same longitude—that is, when the same perpendicular to the ecliptic passes through both. If they have, at the same time, the same latitude—that is, if they are both equally far north or south of the ecliptic—they appear from the earth to be in the same spot of the heavens, and to cover one another. The sun and moon are in conjunction at the period of new moon. In the case of the inferior planets Mercury and Venus, there is an inferior conjunction when the planet is between the earth and the sun, and a superior when the sun is between the earth and the planet. In general, a heavenly body is in conjunction with the sun when it is on the same side of the earth, and in a line with him; and it is in *opposition* to the sun when it is on the opposite side of the earth, the earth being in a line between it and the sun. Planets are invisible when in conjunction with the sun, except in rare cases when an inferior planet passes over the sun's disc, and may be seen as a speck on his surface. Conjunctions are either *geocentric* or *heliocentric*, according as they are actually witnessed from the earth, or as they would be witnessed if observed from the sun. In observing a conjunction from the earth's surface it is usual to reduce the observation to what it would be if made from the earth's centre; by this means the exact times of conjunction are more accurately fixed, and the observations of one astronomer made available to every other, wherever he may be on the earth's surface. *Grand conjunctions* are those where several stars or planets are found together. Chinese history records one in the reign of the Emperor Tehuen-hiu (2514-2436 B.C.), which astronomers calculate to have actually taken place.

Conjuring, as understood at the present day, signifies the production of effects apparently miraculous by natural means.

The art of producing apparently supernatural phenomena has been cultivated from remote antiquity. The earlier professors of the art claimed *bona-fide* supernatural powers; and in ages when the most elementary principles of physical science were unknown beyond a very limited circle, it was not difficult to gain credence for such a pretension. The modern conjurer makes no such claim, but tells the public frankly that his marvels are illusory, and rest either on personal dexterity or on some ingenious application of natural principles. Of the conjurers of remote antiquity we have few reliable records; though it is a tolerably safe conjecture that the prestige of the ancient mysteries rested in no small degree upon effects of natural magic. It may also be gathered that the conjurers of old were familiar with certain forms of optical illusion, in which the use of plane and concave mirrors, and a partial anticipation of the principle of the magic-lantern, played prominent parts. Chaucer mentions illusions of his own day of which the above seems the most probable solution. In the accounts of very early writers, however, large deductions must be made for the comparative ignorance of the observer, and the desire, common to all narrators of extraordinary occurrences, to make the marvel as marvellous as possible. Perhaps the earliest really trustworthy authority is Reginald Scot, who in his *Discoverie of Witchcraft* (1584) has enumerated the stock feats of the conjurers of his day. The list includes swallowing a knife; burning a card and reproducing it from the pocket of a spectator; passing a coin from one pocket to another; converting money into counters, or counters into money; conveying money into the hand of another person; making a coin pass through a table, or vanish from a handkerchief; tying a knot, and undoing it 'by the power of words'; taking beads from a string, the ends of which are held fast by another person; making corn to pass from one box to another; turning wheat into flour 'by the power of words'; burning a thread and making it whole again; pulling ribbons from the mouth; thrusting a knife into the head or arm; putting a ring through the cheek; and cutting off a person's head and restoring it to its former position. Strange to say, many of these feats, which were doubtless already old in the time of Scot, are still performed, with more or less variation of detail, by conjurers at the present day.

The conjurers of Scot's time, and even of much later date, were accustomed, in order to facilitate the substitutions on which a great part of their tricks depended, to wear an apron with pockets, known (from its resemblance to a game-bag) as the *gibécère*. A later school suppressed this tell-tale article of costume, and used instead a table, with cover reaching nearly or quite to the ground. This table concealed an assistant, who worked most of the required transformations, &c., either handing the needful articles to the conjurer as he passed behind the table, or pushing them up through traps in the table-top. Conus the elder, a French conjurer who flourished at the close of the 18th century, made a further improvement by discarding the concealed assistant, and using an undraped table with a secret shelf (now known as the *servante*) behind it, on which his substitutions were made. His immediate competitors did not follow his example, a whole generation of later conjurers, including Comte, Bosco, and Philippe, retaining the suggestive draped table. Its death-blow, however, was struck by Robert Houdin (1805-71), with whom about 1844 a new era began. His miniature theatre in the *Palais Royal* was remarkable for the elegant simplicity of its stage arrangements, and in particular for the complete suppression of the *boîte à compère* ('wooden confederate'), as Robert Houdin

sarcastically terms it. The new style took with the public, and by degrees Robert Houdin's contemporaries found themselves compelled to follow his example.

To Robert Houdin belongs the credit of devising some of the best-known and most ingenious pieces of magical apparatus, as also that of the application of electro-magnetism, then little understood, to the production of magical effects. The well-known magic drum, that beats without visible drumsticks, the magic clock and bell, and the chest, light or heavy at command, are all fruits of his inventive genius.

The most modern school of conjurers, following the lead of Wiljalba Frikkell, and at present represented by Hartz, Hermann, Buatier de Kolta, Verbeck, Lynn, Bertram, &c., generally aim at producing their magical results with the minimum of visible apparatus. There are, however, signs of a reaction in favour of more spectacular illusions, such as those of Messrs Maskelyne and Cooke, in which the resources of optical and acoustic, as well as mechanical science, are laid under contribution in aid of conjuring proper. See the articles *MAGIC* and *JUGGLESERS*.

For practical information as to the methods of conjurers, see Hoffmann's *Modern Magic* (6th ed. 1886) and *More Magic* (1889); *Sleight of Hand*, by Edwin Sachs (2d ed. 1885); Robert Houdin's *Secrets de la Prestidigitation et de la Magie* (1868; reprinted in 1878 under the title of *Comment on devient Sorcier*) and *Magie et Physique Amusante* (1877); and an anonymous work, *Recueil de Tours de Physique Amusante* (published by De La Rue of Paris). The three last-named works have been translated into English by Hoffmann, under the titles of *The Secrets of Conjuring and Magic*, *The Secrets of Stage Conjuring*, and *Drawing-room Conjuring* respectively.

Conkling, ROSCOE, American politician, born in Albany, New York, 30th October 1829, was admitted to the bar in 1850, sat in congress as a Republican in 1858-62 and 1864-66, and was elected to the United States senate in 1867, 1873, and 1879. He was now an influential member of his party; in 1876 he received ninety-three votes for the presidential nomination, and, in 1880, by his support of Grant, and his personal opposition to Blaine, divided the Republicans into two sections. In 1881 he and his colleague suddenly resigned from the senate, owing to a dispute with President Garfield on a question of patronage, and sought re-election; but after a warm canvass, both were rejected, though vigorously supported by Vice-president Arthur. Conkling afterwards practised law in New York city. He died 18th April 1888.

Conn, LOUGH, a picturesque Irish lake in the north of County Mayo, together with Lough Cullin (from which it is separated by a narrow neck of land), 13 miles long, and 1 to 3 broad. It lies in a wild romantic region of hills, glens, rocky slopes, precipices, broken ground, and bogs, contains many islets, and has bold shores.

Connara-cer, a sub-order of Terebinthaceæ, including about 25 species, all tropical, of which the most important is *Onthalobium Lambertii* of Guiana, the source of the zebra-wood of cabinet-makers.

Connaught, the most westerly and the smallest, both in extent and population, of the four provinces of Ireland. It is bounded N. and W. by the Atlantic; E. by Ulster and Leinster, from the latter of which it is separated by the Shannon; and S. by Munster. It contains the counties of Galway, Leitrim, Mayo, Roscommon, and Sligo. Greatest length from north to south, 105 miles; greatest breadth, not including Achil Island, 92 miles. Area, 6863 sq. m. The west coast has many fine bays and harbours, and the surface, especially in the western half, is mountainous and

rugged, forming remarkably grand and picturesque scenery. The people are still almost purely Celtic. In ancient times the O'Connors were kings of Connaught. In 1590 the province was divided by the English into six counties, its present five, with Clare, afterwards joined to Munster. In 1874 the title Duke of Connaught was conferred on Prince Arthur, third son of Queen Victoria. The territorial regiment, the Connaught Rangers, once the 88th foot, now comprises the old 88th and 94th regiments (with four battalions of militia). Pop. (1841) 1,420,705; (1851) 1,015,479; (1861) 919,135; (1881) 817,197, a decrease due to famine and emigration.

Connecticut (*kon-ut'-e-cut*), one of the six New England states of the American Union, is bounded N. by Massachusetts, E. by Rhode Island, S. by Long Island Sound, W. by the state of New York. It is the smallest in area of all the states, excepting Rhode Island and Delaware; but there were in 1880 ten states smaller in population than Connecticut. Its area is 4845 sq. m., or nearly two-thirds that of Wales. It is one of the most densely peopled states of the Union. A great part of the surface is rocky and uneven, and the Green and Taconic Mountains of the Appalachian system occupy a considerable part of the western extremity of the state; but the mountains here are all insignificant in respect of height. Much of the surface is not easily cultivated, and rather unfertile; but a considerable part of the valley of the Connecticut River is very productive, tobacco being a leading product of this section. Hay, potatoes, maize, oats, and rye are the principal crops. Grazing and milk farms, orchards and market-gardens, are profitably sustained in all parts of the state.

The Connecticut River, which, rising in New Hampshire, forms the boundary between that state and Vermont, and flows south through Massachusetts, crosses Connecticut also, and after a course of about 450 miles enters Long Island Sound, 30 miles east of New Haven. It is navigable for vessels of light draught as high as Hartford. In the east part is the River Thames, and in the west the Housatonic, both of which afford some navigation. But the greatest value of the very numerous streams is as a source of water-power. In 1880 over one-half the power employed in the manufacturing of the state was water-power; and the utilised water-power was returned by the United States census as 12'63 horse-power per sq. m. The surface-rocks are mostly Azoic, with the principal exception of a strip of Triassic sandstone or psammite running along the Connecticut River. This brown sandstone is largely quarried at Portland and East Haven, as are excellent red and plain granites and gneissoid building-stones at many points; valuable serpentine and verdantique exist near New Haven. Some quarries yield excellent flagstones of gneissoid character; the so-called 'trap' rock, here really a diabase of Triassic date, is also wrought; and in the north-west good limestones of Lower Silurian age are quarried. Brown hematites are extensively wrought in the north-west section, and yield excellent iron. Deposits of lead, copper, and cobalt have been locally mined. Useful mineral-waters occur at various points. The climate is very changeable, and is rather severe in winter, but generally healthful. Nearly the whole surface was once richly forested; but no very extensive areas are now covered by large timber; still the aggregate production of wood for building purposes and for fuel is very considerable. The sea-coast affords a number of good harbours. Most of the maritime enterprise is now directed to the coast-wise trade, the whale

and seal fisheries having declined. Oyster-fishing is engaged in largely and very systematically, as is the taking of fish for oil and fish-guano. The manufactures of Connecticut are carried on upon a very extensive scale, and are of exceedingly varied character; and notwithstanding its small area, the state stands in the first rank as respects the amount and aggregate value of manufactured goods. Clocks, hardware, india-rubber goods, firearms, silks and other textiles, and small-wares in great variety, are produced on a large scale. Life, fire, and accident insurance, and the publication of subscription books, receive great attention. The state is well supplied with railways. In very few parts of the world has more been done for popular education than in this state. Private, denominational, and parochial schools of every grade supplement the work of this public-school system. The latter dates from 1644. Yale University at New Haven comprises collegiate and post-graduate courses, besides medical, theological, scientific, law, and art schools, and takes a very high place among the seats of learning in the country. Mention should be made of Trinity College, Hartford, and of the Wesleyan University at Middletown. There are also divinity schools at Hartford (Congregationalist) and Middletown (Episcopalian). The state supports a full complement of institutions for correction and charity. Among the principal cities and towns are Hartford (the capital), New Haven, Bridgeport, Waterbury, Meriden, Norwich, Norwalk, New Britain, Danbury, Derby, Stamford, and New London.

The old stock of inhabitants were of English Puritan origin, but of later years there has been a large immigration of Irish, German, English, and others. The colony of Connecticut may be said to date from 1634, when the movement began in which Hartford, Wethersfield, and Windsor were settled by persons removing from Massachusetts, and displacing a slender colony of the Dutch. This movement was in reality the secession of the more democratic element from Massachusetts. Saybrook, named in honour of Lord Say-and-Sele and Lord Brooke, was the nucleus of a separate colony which in 1644 was united to Connecticut, as was in 1662 the New Haven colony, founded in 1638. The Connecticut colony adopted a constitution in 1639, 'the first written democratic constitution on record.' The royal charter of 1662 was exceedingly liberal, it being essentially a confirmation of the older constitution; and it continued in force even after the independence of the American states, but in 1818 was replaced by the present state constitution. A large part of Long Island was for a considerable period under the government of the colony. Prominent events in Connecticut history have been the bloody war with the Pequot Indians, 1637; the governorship of Sir Edmund Andros, during a part of which (1687-88) the colonial charter was in abeyance, and according to the very doubtful but commonly received account was only saved from destruction by being hidden for a time in a hollow tree, the Charter Oak at Hartford. Slavery was abolished in 1818. Pop. (1870) 537,454; (1880) 622,700, of whom 129,992 were foreign born. See Alex. Johnston's *Connecticut* (1887).

Connemara is the name of the wild and picturesque district which forms the westernmost division of County Galway. Its interesting scenery, its lakes, streams, and inlets abounding in fish, attract many fishers and tourists. Connemara is also called Ballynahinch.

Connoisseur, a term borrowed from the French, to designate persons who, without being themselves artists, are competent to pass a critical

judgment upon the merits of works of art, especially in painting and sculpture. The Italian equivalent for connoisseurs is *Cognoscenti*.

Conodonts, minute fossils met with in Palaeozoic strata. They are variable in form, and look very like the teeth of different kinds of fishes, some being simple slender pointed sharp-edged cones, while others are more complex, resembling in form the teeth of certain sharks. Their affinities are very uncertain—some maintaining that they are really the minute teeth of fishes allied to the living hag-fishes and lampreys—others suggesting that they have more analogy with the hooklets or denticles of annelids and naked molluscs.

Conoid, a solid formed by the revolution of a conic section round its axis; such are the sphere, paraboloid, ellipsoid, and hyperboloid.

Conolly, JOHN, physician, born at Market Rasen, Lincolnshire, in 1794, graduated at Edinburgh in 1821, and in 1827 settled in London, where he was for two years professor of the Practice of Medicine in University College. In 1839 he was appointed resident physician to the Asylum for the Insane at Hanwell; this post he held till 1844, and afterwards he was retained as visiting physician. Here, under Conolly, all forms of mechanical restraint were from the first entirely discontinued; and although his views were admittedly not original, it is mainly to his earnestness and eloquence that the revolution in asylum management in England is due. His best works are those on the *Construction and Government of Lunatic Asylums* (1847), and kindred subjects. He died 5th March 1866. See the Memoir by Sir James Clark (1869).

Conquest. In the law of succession in Scotland heritable property acquired during the lifetime of the deceased, by purchase, donation, or exambion, was called Conquest, in opposition to that to which he has succeeded, which is called Heritage. The distinction was abolished by the Conveyancing Act, 1874. Conquest, in a marriage-contract, is property acquired by the husband during the marriage as distinguished from what he possessed before the marriage. Such property was frequently but is now rarely settled either on the heir or on the issue of the marriage.

Conquistado-res (Span., 'conquerors') is a collective term for the Spanish conquerors of America, such as Cortes, Balboa, Pizarro. See the articles under their names; as also MEXICO, PERU, &c.

Conrad, or KONRAD I., king of the Germans, was the son of the Count of Franconia, and the nephew of the Emperor Arnulf. He was elected king (practically emperor of Germany) on the extinction of the direct line of the Carolingians in 911 A.D. He gradually re-established the imperial authority over most of the German princes, carried on an unsuccessful war with France, and at last fell mortally wounded at Quedlinburg (918), in a battle with the Hungarians, who had repeatedly invaded his dominions. See GERMANY.

Conrad II., king of the Germans, and Roman emperor, was elected after the extinction of the Saxon imperial family in 1024. He was the son of Henry, Duke of Franconia, and is by many considered as the founder of the Franconian dynasty. Immediately after his election he commenced a tour through Germany to administer justice. In 1026 he crossed the Alps, chastised the rebellious Italians, was crowned at Milan as king of Italy, and he and his wife Gisela were anointed emperor and empress of the Romans by the pope. He was soon recalled to Germany to put down four formidable revolts, in which he succeeded so well that by 1033 peace was restored. In 1032 he

had succeeded to the kingdom of Burgundy, which he annexed to the empire. In 1036 a rebellion in Italy again compelled him to cross the Alps; but his efforts to restore his authority were this time unsuccessful, and he was forced to grant various privileges to his Italian subjects. Shortly after his return he died at Utrecht, 4th June 1039. Conrad was one of the most remarkable of the earlier monarchs of Germany. He reduced the dangerous power of the great dukes of the empire, and defended the rights of the humbler people against oppression by the nobility.

Conrad III., king of the Germans, the founder of the Hohenstaufen (q.v.) dynasty, was the son of Frederick of Swabia, and was born in 1093. While under twenty years of age, Conrad, with his elder brother Frederick, had bravely supported Henry V. against his numerous enemies, and in return that monarch granted Conrad the investiture of the duchy of Franconia. He subsequently contested the crown of Italy with the Emperor Lothaire of Saxony, but was compelled to resign his pretensions. On the death of Lothaire, the princes of Germany, fearing the increasing preponderance of the Guelph party, and attracted by his brilliant courage, moderation, and goodness, offered Conrad the crown, and he was accordingly crowned at Aix-la-Chapelle, 21st February 1138. He was immediately involved in a quarrel with Henry the Proud, Duke of Bavaria and Saxony, and head of the Guelph party in Germany; and the struggle was continued under Henry's son and successor, Henry the Lion (q.v., and see GUELPHS AND GIBELINES). While Germany was thus convulsed, the state of Italy was not a whit more peaceable. The several belligerents besought Conrad's assistance, but he well knew the natural inconstancy of the Italians, and determined to stand aloof. Soon after this St Bernard of Clairvaux commenced to preach a new crusade, and Conrad, seized with the general infatuation, set out for Palestine at the head of a large army (see CRUSADES). A new attempt by the Duke of Bavaria to regain his dukedom was defeated by the nephew of Conrad, whose health had broken during the crusade. Conrad died at Bamberg in 1152. See GERMANY.

Conradin OF SWABIA, the last descendant of the imperial House of Hohenstaufen (q.v.), was the son of Conrad IV. (1237-54), and was born in 1252, two years before his father's death. His uncle Manfred (q.v.) had assumed the crown of Sicily on a rumour of Conradin's death, though he declared himself ready to give it up to the rightful heir. But Pope Clement VI.'s hatred of the Hohenstaufens led him to offer the crown of the Two Sicilies to Charles of Anjou, a consummate warrior and able politician. Charles immediately invaded Italy, and met his antagonist at Benevento, where the defeat and death of Manfred, in 1266, gave him undisturbed possession of the kingdom. But the Neapolitans, detesting their new master, sent deputies to Bavaria to invite Conradin, then in his 16th year, to come and assert his hereditary rights. Conradin accordingly made his appearance in Italy at the head of 10,000 men, and being joined by the Neapolitans in large numbers, gained several victories over the French, but was finally defeated near Tagliacozzo, 22d August 1268, and taken prisoner along with Frederick of Baden and other comrades. The two unfortunate princes were, with the consent of the pope, executed in the market-place of Naples on the 20th October. A few minutes before his execution, Conradin, on the scaffold, took off his glove, and threw it into the midst of the crowd as a gage of vengeance, requesting that it might be carried to his heir, Peter of

Aragon. The tragic tale has furnished materials for many poets. See SICILIAN VESPERS; also Del Giudice, *La Condanna di Corradino* (Naples, 1876).

Conrad von Würzburg, one of the most celebrated poets of the middle ages, died at Basel in 1287. Conrad is fertile in imagination, learned, and—although marking the decline of Middle High-German poetry by his prolix and artificial style—probably the most perfect master of German versification that had appeared up to his own day. His last poem, which he left in an unfinished condition, has for its subject *The Trojan War*. But Conrad appears to most advantage in his smaller narrative poems, of which the best are *Engelhart*, *Otto*, *Der Welt Lohn*, *Silvester*, *Alexius*, *Der Schwanritter*, and *Die Goldene Schmiede*. His *Lieder* have been edited by Bartsch (1870).

Consalvi, ERCOLE, CARDINAL, a distinguished reformer of abuses in the Papal States, was born at Rome, June 8, 1757. He was made cardinal and secretary of state by Pope Pius VII., and in this capacity concluded the concordat with Napoleon in 1801. His staunch maintenance of the rights of his own sovereign against the insidious encroachments of France offended Napoleon. He was the papal representative at the Congress of Vienna, and secured the restoration of the Papal States. As papal secretary he reformed numerous abuses, suppressing all monopolies, feudal taxes, and exclusive rights. He was a liberal patron of science, but especially of the fine arts, and employed his leisure in the study of literature and music. In diplomacy he displayed great address, and was generally successful. He died in Rome, January 24, 1824.

Consanguinity (Lat. *con*, 'together,' and *sanguis*, 'blood'), the relationship which subsists between persons who are of the same blood. It is either *direct*, which is the relationship between ascendants and descendants, or *collateral*, between persons sprung from a common ancestor. In the direct line, a son is said to stand in the first degree to his father; a grandson, in the second degree to his grandfather; and so on.—*Affinity* (q.v.) is the relationship brought about by marriage between a husband and the blood-relations of his wife, or between a wife and the blood-relations of her husband.

Consanguinity and affinity have been in all parts of the world more or less looked on as impediments to marriage between the parties related. Among the ancient Persians and Egyptians, marriages were sometimes sanctioned between brother and sister, and even father and daughter; and in the book of Genesis we read of Abraham marrying his half-sister.

The Roman law prohibited marriage between ascendants and descendants, a prohibition extended to relations by adoption. In the collateral line, the prohibited degrees included brother and sister, and all cases where one party stood *in loco parentis* to the other, as uncle and niece. Marriage between cousins-german, at one time prohibited, was declared lawful by Arcadius and Honorius. The degrees prohibited in consanguinity were by Constantine also prohibited in affinity.

By the old canon law and early decretals, marriages were prohibited between persons as far removed as the seventh degree of consanguinity or affinity. The fourth council of Lateran, 1215 A.D., narrowed the prohibition from the seventh to the fourth degree; i.e. the grandchildren of cousins-german. A marriage between persons related in any of these ways was accounted incestuous, and the children bastards. The pope assumed the right of granting dispensations from impediments to

marriage arising from consanguinity and affinity, a power which seems to have been first exercised in the 12th century.

In the countries which embraced the Reformation, a general relaxation took place in the prohibitions to marriage from consanguinity and affinity. In England, an act of 1547 allowed all persons to marry who were not prohibited by the Levitical law; and according to the interpretation put on this statute, the prohibitions included all relations in the direct line, brother and sister, and collaterals, when one party is brother or sister to the direct ascendant or descendant of the other; the degrees prohibited in consanguinity being equally prohibited in affinity. In Scotland, acts of 1567, professing to take the Levitical law as the standard, assimilated the prohibitions from consanguinity and affinity to those of England. In France, the Code Napoléon prohibits marriage between ascendants and descendants lawful or natural, and persons similarly connected by affinity; and in the collateral line between brothers and sisters lawful or natural, and persons similarly connected by affinity. Marriage between uncle and niece, and aunt and nephew, is also prohibited. In various countries of Europe, as Denmark, no prohibitions from affinity, except in the direct line, are recognised. In most of the United States of America, marriage is allowed between uncle and niece. See AFFINITY, DECEASED WIFE'S SISTER; and for exogamy and curious savage methods of counting relationship, MARRIAGE.

On the much-vexed question whether the marriage of relations tends to injure the constitution of their offspring, either by the intensification of hereditary taint or more directly, see *The Marriage of Near Kin* (2d ed. 1888), by A. H. Huth (who takes the negative view), and the bibliography there given of works on both sides of the question. See also BREED, CATTLE.

Conscience. See ETHICS.

Conscience, HENDRIK, a popular Flemish novelist, was born December 3, 1812, at Antwerp. His father, the inspector of the dockyards there, was a native of Besançon, but his mother was of Flemish birth. At fifteen the boy had to shift for his living as an under-master in a school, but at the outbreak of the revolution in 1830 he joined the Belgian ranks, and served till 1836. Patriotism and poverty together impelled him to write, and between them produced in 1837 his first volume in Flemish, *In't Wonderjier*, 1566. Wappers the painter finally got him appointed in 1841 to an office in the Antwerp Academy, which he continued to fill until 1854. Three years later he received a place in the local administration of Courtrai, and became in 1866 director of the Wiertz Museum at Brussels. Here he died, September 10, 1883. His *Phantasy* (1837), a fine collection of tales, and his most popular romance, *De Leeuw van Vlaenderen* (1838), early made his name dear to his fellow-countrymen; but it was his series of charming pictures of quiet Flemish life, beginning with the little book, *Hoe men schilder wordt* (1843), that, through French, German, and English translations, carried his fame over Europe. Amongst those translated into English, besides the *Lion of Flanders*, are *Blind Rosa*, *Ricketicketack*, *The Poor Gentleman*, *The Miser*, and *The Demon of Gold*. The historical accuracy of his *Geschiedenis van België* (1845) was somewhat impaired by his Catholic predilections. The vast popularity of Conscience's novels depended mainly on the unflagging vigour and interest of the incidents in which they abounded, although these often enough defied all historical consistency and verisimilitude alike. It should be remembered to his credit, as, indeed, it

was his own proudest boast, that in his hundred volumes he had never painted vice in seductive colours. A complete collection of his works appeared at Antwerp in 10 volumes, 1867-80; a German translation of the same at Münster in 75 small volumes, 1846-84. See his *Life*, in French, by Cekhoud (Brussels, 1881).

Conscience, COURTS OF, IN ENGLAND. These were courts for the recovery of small debts, constituted by special local acts of parliament in London, Westminster, and other trading districts. The county courts have superseded them. See **COUNTY COURTS**.

Conscience Money, money paid to relieve the conscience, is a not inapt term for money sent to the Chancellor of the Exchequer in payment of a tax that had previously been evaded, and in regard to which a tender conscience feels that something remained to be done. The conscience money is often sent anonymously.

Consciousness. This is the most comprehensive term employed in designating the mind. In the widest and most unexceptionable meaning, consciousness is a term which includes all mental states, operations, or processes, and, as has been truly said, it is not strictly susceptible of definition, seeing that we can have no experience of the unconscious. We may specify different modes or varieties of consciousness, such as thoughts, feelings, and volitions; but the quality in which they all agree, and which constitutes them mental facts or states of consciousness, cannot be otherwise explained than by a mere reference to the constant experience of every human being. Consciousness, in this its strict sense, thus embraces the whole field of mental experience, and the expression 'facts of consciousness' is frequently used as synonymous with psychical facts or facts of mind to designate the subject-matter of psychology.

Popularly, therefore, when we are mentally alive, or performing any of the recognised functions of the mind, we are said to be conscious; while the total cessation of every mental energy is described by the term 'unconsciousness,' among other phrases. In dreamless sleep, in stupor, fainting, and under the influence of the anæsthetic drugs, we are unconscious; in waking, or rallying into renewed mental activity, we are said to become conscious.

The difficulties of the subject, however, have prevented a perfectly definite and uniform usage from being adhered to. As the mind in its waking or active condition may be more or less excited, or vary in the intensity of its manifestations, there are degrees of consciousness; and, accordingly, the name is apt to be applied to denote the higher degrees in opposition to the lower. Thus, in first learning to write, to cast up sums, to play on an instrument, or to ride a bicycle, our mind is put very much on the stretch; in other words, we are very much excited or highly conscious. But when years of incessant practice have consummated the process into a full-formed habit, a very small amount of mental attention is involved; and we may then be said to perform the work all but unconsciously. Such habitual actions are frequently designated secondarily automatic, and Sir W. Hamilton, for example, speaks in this connection of 'unconscious mental modifications.' But as he has previously defined consciousness as co-extensive with all mental phenomena, such a phrase evidently involves a contradiction in terms, being equivalent to unconscious consciousness. It is explained, though not justified, by the (unavowed) double use of the term consciousness just adverted to. Later writers have sought to escape from this inconvenient terminology by speaking of the more obscure mental processes as 'sub-conscious.' Stress is laid by

them upon the infinite gradations of consciousness, and some amount of consciousness, however infinitesimal, is postulated so long as we can speak with propriety of mental phenomena at all. This sub-conscious region is understood to include not only the phenomena of habit referred to above, but the mass of organic or bodily feelings which, though intellectually unanalysed, are constantly present as a kind of background to our more distinct consciousness, and mainly determine both our habitual temperament and our varying moods. The hypothesis is also employed to explain the phenomena of memory as well as that instinctive basis of human life to which, under the name of the Unconscious, Hartmann (q.v.) has of late assigned such important philosophical functions.

Consciousness is sometimes used in a special sense to denote the mind's cognisance of itself, as opposed to the cognisance or examination of the outer world. Hence, in studying our own minds, we are said to be using consciousness as the instrument; but in studying minerals or plants, we resort to external observation by the senses. A contrast is thus instituted between consciousness and observation, which contrast gives to the former word a peculiarly contracted meaning; for in the wide sense above described, observation is truly an act of consciousness. But such a usage is confusing and undesirable, and has been generally abandoned by accurate writers. The study of our own mind may be more appropriately expressed by such phrases as 'self-consciousness,' 'reflection,' or 'introspection.'

Important philosophical points are involved in the determination of the *conditions* of consciousness, or the circumstances attendant on the manifestation of mental energy. The most general and fundamental condition of our becoming conscious is difference or *change*. The even continuance of one impression tends to unconsciousness; and there are a number of facts that show that if an influence were present in one unvarying degree from the first moment of life to the last, that influence would be to our feeling and knowledge as if it did not exist at all. This condition of our mental life has been formulated by Professor Bain as the Law of Relativity. For the varieties or divisions of our conscious states, see **MIND**. See also **PERSONALITY**.

Conscription has been defined as the call to military service by the drawing of lots, a certain annual contingent of men for the army being selected by lot from the youths who have reached military age, while a man with sufficient means has the right to buy himself off, or pay for a substitute. This system obtained in France, with intervals, from 1798 until 1872, when substitutes were abolished and personal military service made obligatory upon every Frenchman not physically incapacitated. All such must enter the army at the age of twenty; but those who choose to enlist may do so at eighteen. The term, originally twenty years, was extended by the Military Bill of 1888 to twenty-five—viz. three in the regular army, six and a half in the army reserve, six in the territorial army (militia), and nine and a half in the territorial reserve. At forty-five years of age liability to service ceases. A register is kept of the number of youths in France who reach the age of twenty in each year (about 280,000). All under 5 feet 2 inches in height are exempt; also any whose natural infirmities unfit them for active service; the eldest of a family of orphans; the only son of a widow, or of disabled fathers, or of fathers above seventy years of age; and the pupils at certain colleges. Moreover, if the younger of two brothers is efficient, the elder is exempt; and if of two only brothers one is already in the army, or

has retired through wounds or infirmity, the other is exempt. Culpits and felons are not allowed to enlist.

A similar law of universal service has existed in Prussia since 1813, and in 1887 it was made even more severe than formerly throughout the whole German empire. Russia, Italy, and all the chief European nations have also adopted this method of recruiting.

In the United Kingdom a form of conscription was created by the Ballot Act of 1860 which provides for all males over 15 feet 2 inches between the ages of eighteen and thirty being called upon to serve in the militia, but is held in abeyance by an annual act of parliament. In the Channel Islands, service in the militia is always compulsory for all natives, tradesmen, and owners of real property, who are physically fit, from sixteen to forty-five years of age. Breaches of discipline are punished by the civil magistrate by fine or imprisonment.

Consecration is the act of solemnly dedicating a person or thing to the service of God. In the Jewish law, rites of this nature are frequently enjoined, the Levites and priests, the tabernacle and altar, &c. being specially dedicated or consecrated to God; and analogous forms occur in most pagan nations. Among Christians the word consecration describes—(1) the ordination of bishops. The Nicene Council (can. 4) requires the ceremony to be performed by not less than three bishops. This rule is maintained by the Church of England. Among Roman Catholics the pope may permit consecration by one bishop and two priests. (2) The hallowing of the elements in the eucharist, by the words of institution according to Roman Catholics and Anglicans; by the invocation of the Holy Spirit according to the Greeks. (3) The dedication of churches; first mentioned by Eusebius, *Hist. Eccles.* x. 3. The rites, originally very simple, have become long and elaborate in the Church of Rome, though the present form is in substance as old as the Sacramentary of St Gregory. In the English Church the bishop chooses his own form. That most generally used was drawn up by the Anglican episcopate in 1712. In the American Episcopal Church a form was appointed in 1799. (4) The benediction of abbots and abbesses according to forms prescribed in the Roman Pontifical. It is usually performed by a bishop. (5) The consecration of altars, chalices, and patens by the bishop with the chrism or hallowed oil. The consecration of altars is mentioned by councils of the 6th century, that of chalices and patens in the Gregorian Sacramentary.

Consecutive, a term in Music. In part writing consecutive octaves or consecutive fifths, according to the rules of harmony, are strictly forbidden, though there are many exceptions to this in modern music.

Consent is the foundation of all contracts and legal obligations. The doctrine that the free consent of the parties bound, and not the will of any earthly legislator, or the form in which that will is expressed, constitutes the binding element in contracts, flows as an inevitable logical consequence from the doctrines of personal and political freedom. All that either civil or ecclesiastical authority can do is to ascertain, at the instance of one or other of the parties, whether consent has or has not been given.

Conservation of Energy. See ENERGY.

Conservative, as applied to one of the two great parties in English politics, was first used by J. W. Croker in an article in the *Quarterly* for January 1830, and was by Macanlay in the *Edinburgh* for 1832 referred to as a 'new cant word.'

Conservative accordingly began to supersede *Tory* about the time of the Reform Bill controversies. See *TORY*.

Conservatoire, or CONSERVATORIUM (Ital. *conservatorio*), forms of a name given by the Italians to schools instituted for the purpose of advancing the study of music and maintaining its purity. In the earliest times these schools were partly attached to benevolent institutions and hospitals; others, again, were supported by opulent private individuals. They were originally intended for foundlings, orphans, and the children of poor parents. Some trace their origin to St Ambrose, Bishop of Milan, in the 4th century, or St Leo, who flourished in the 5th. They were largely developed by Gregory the Great. The scholars, male and female, all received free board, lodging, and clothing, and were taught to sing and play. Extra boarders were also admitted on paying a fee. In Naples there were at one time four such schools, while in Venice there were four expressly for females. In 1808 the Neapolitan conservatoires were reduced to one, under the name of Reale Collegio di Musica. The Venetian conservatoires shared in the downfall of the Venetian republic. A new grand conservatoire was founded at Milan in 1808, which still exists. In France the necessity of a school for educating singers gave rise to the *École Royale de Chant et de Déclamation* in 1784. During the French Revolution, in consequence of the scarcity of instrumental musicians for the army, the government decreed the erection of an Institut National de Musique in 1793, which was changed into the present establishment in 1795 under the name of the Conservatoire de Musique. The yearly expenses of this conservatoire were fixed at 240,000 francs, the number of masters was 125, and the pupils of both sexes amounted to 600. In 1802 the expense was reduced to 100,000 francs, with a corresponding reduction in the number of masters and pupils, but the original sum and number of pupils has now been nearly reached again; the professors are at present 77 in number. The tuition is divided over more than seventy different classes, in which all pertaining to music and also declamation is taught by the best masters. The elementary works published by this conservatoire for all instruments are known over the whole world, and it possesses a library and museum of the first importance. The post of director has been held by an illustrious succession—Cherubini, 1822-42; Auber, 1842-71; and then, M. Ambroise Thomas. Other important conservatoires are those of Brussels (founded 1833), Prague, Vienna (1816), and the great conservatorium of Leipzig, established in 1842 under the auspices of Mendelssohn; also those of Cologne, Munich, Stuttgart, Berlin, &c. The Royal College of Music in London, which received a charter in 1882, is designed to rival the conservatoires of the Continent. There are several of note in the United States, especially the Boston Conservatory of Music (1867), the New England Conservatory of Music (1870), also in Boston, and the Grand Conservatory of Music of the City of New York (a corporation); and there are reputable schools of music, termed conservatories, in almost all the principal cities. The name conservatoire is used for other than musical schools in France. There is thus a *Conservatoire des Arts et Métiers* at Paris.

Conservators of the Peace, a title usually applied to knights elected in each shire from the 12th century onwards for the conservation of the peace. They were in fact the predecessors of the Justices of the Peace (q.v.), by whom they were superseded.

Conservatory. See PLANT-HOUSE.

Conserve. See PRESERVES.

Considérant, VICTOR-PROSPER, a French Socialist, was born in 1808 at Salins, in the department of Jura. After being educated at the Polytechnic School of Paris, he entered the army, which, however, he soon left to promulgate the doctrines of the socialist Fourier. On the death of his master (1837), Considérant became the head of his school, and undertook the management of the *Phalange*, a review devoted to the spread of their opinions. Having gained the support of a young Englishman, Mr Young, who advanced the required sum of money, Considérant established, on a large estate in the department Eure et Loire, a socialist colony or *Phalanstère*; but the experiment failed, and with it the *Phalange* fell to the ground. Thereafter he continued to promote his views in the *Démocratie Pacifique*. Among his numerous writings, the chief is the *Destinée Sociale*, dedicated to Louis-Philippe. In 1849 Considérant was accused of high treason, and compelled to flee from France. In Texas he founded a socialist community, *La Réunion*, which flourished for a time, but has since come to nothing. Considérant returned to France in 1869. See FOURIER and SOCIALISM.

Consideration, in Law, the thing given, or done, or abstained from by agreement with another, and in view of that other doing, giving, or abstaining from something. An obligation incurred without consideration is, in England, termed voluntary, in Scotland gratuitous; if for consideration, it is so styled in England, but in Scotland it is called onerous. Considerations are divided in England into good and valuable, the former being affection for a near relative, the latter a pecuniary or other tangible benefit, or marriage. But 'good' as distinguished from 'valuable' consideration has now no legal effect in England. There is no corresponding division in Scotland, but the fulfilment of a natural obligation, such as that of aliment, is often recognised as supporting a transaction which would otherwise be inoperative against creditors. In Scotland, however, there is, as a general rule, no need for consideration to make a contract valid, while in England no action lies for breach of a contract not under seal, unless there has been valuable consideration, and the courts never enforce specific performance of a gratuitous contract, even though it is under seal. This doctrine does not mean that consideration must be adequate in view of the court. But the excess of consideration is an important fact in the setting aside of obligation obtained by means of pressure or undue influence. The English doctrine of unconscionable bargains is not, however, recognised in Scotland. Where the consideration for an obligation totally fails, an action of repetition lies.

There are some circumstances which, in both countries, warrant the setting aside of obligations without consideration, whether made by deed or not. In England they are void as against *bonâ-fide* purchasers, and void as against creditors where the grantor is indebted to such creditors at the time to the extent of insolvency. A similar rule to the latter, with respect to creditors generally, is established in Scotland by the Act 1696, chap. 5, and by 1621, chap. 18, without proof of insolvency when the deed is granted to a near relation, or a person in a confidential situation. As regards sales of land in Scotland, these are made on the faith of the records, and the first registered conveyance prevails. And all obligations for which the consideration is illegal or immoral are in both countries void.

In the United States, consideration in law has the same general signification as in England, and is subject to the same general divisions, 'good' or

'meritorious' and 'valuable.' A consideration is an essential element enforceable in law, and must be actual and expressed, or the instrument must be such as to bear evidence of a consideration. By common-law statutes re-enacted in the United States, negotiable paper and sealed instruments are declared to bear this evidence; but in some states by usage, and in others by statute, courts of equity are empowered to set aside these instruments for want of, or a failure of, a valid and legal consideration upon the ground that the instrument was executed upon a promise or stipulation not fulfilled.

Consignment, in Mercantile Law, is the term applied to goods which are placed in the hands of an agent or factor for sale, or for some other specified purpose. If the consigner fails, the consignee has generally a lien on the unsold goods for advances; if the consigner has to pay bills granted by consignee for advances, he may generally get back his consignment so far as unsold.

Consistory (Lat. *consistorium*), properly a place of assembly, but in the later Latinity the word came to signify the particular place where the privy-council or cabinet of the Roman emperor met, and after the time of Diocletian and Constantine, the council itself. The form of the imperial consistory passed over into the early Christian church. The bishops established their consistories; and the highest ecclesiastical court, composed only of cardinals (the College of Cardinals), which meets in the Vatican, under the presidency of the pope, to determine all such matters as the appointment of cardinals, archbishops, bishops, &c., still bears this name, as do also the private councils which the pope can call at his pleasure. The Protestant Church of Germany was induced to perpetuate the consistorial courts, principally because the episcopal authority passed into the hands of territorial princes not familiar with ecclesiastical affairs. The first Lutheran consistory was established at Wittenberg in 1542. The Lutheran consistories exercise a supervision and discipline over religion and education, over the clergy and the schoolmasters, and examine the theological candidates on their trials for license and ordination. They have the regulation of divine worship, the administration of church property, and at an earlier period possessed a certain jurisdiction in regard to marriage.—In the French Protestant churches the consistory possesses a more restricted jurisdiction than in Germany. In England the word is used to denote the court Christian or spiritual court. Every archbishop and bishop has a consistorial court, held either in his cathedral or other convenient place, before his chancellor or commissary, for ecclesiastical causes. In Scotland the consistorial courts have lapsed into the commissary-courts. See COMMIS-SARY.

Consolato del Mare. See MERCANTILE LAW.

Console (Fr.), in Architecture, a projection resembling a bracket, frequently in the form of the letter S, used to support cornices, or for placing busts, vases, or figures on. Consoles were often richly ornamented in the under part. The illustration, from Parker's *Glossary*, is from the palace of Diocletian at Spalatro.

Consolidation Acts, acts of parliament which combine or consolidate into one general statute the enactments of several special measures,

Console.

such as the Railways Clauses Consolidation Act, 1845, the Titles to Land Consolidation Act, 1868, &c.

Consols, a contraction of Consolidated Annuities. In incurring the national debt, government borrowed money at different periods on special conditions, being generally the payment of an annuity of so much per cent. on the sum borrowed. Great confusion arose from the variety of stocks thus created, and it was thought expedient to consolidate them into one fund, kept in one account at the Bank of England. The Consolidated Annuities Act was passed in 1749-50, consolidation being completed in 1757. For consolidation of the Funded Debt subsequent to that period, see DEBT (NATIONAL).

Consonance is a combination of notes which can sound together without the harshness produced by beats. See SOUND, MUSIC.

Consonant. See LETTERS.

Consort, literally, one who throws in his lot with another. In English constitutional law, the term is applied to the husband or wife of the reigning sovereign, viewed not in a private but in a public capacity, as participating to a certain limited extent in the prerogatives of sovereignty. A queen-consort is specially so named in distinction from a queen-regnant, who holds the crown in her own right, as Queen Elizabeth and Queen Victoria, and from a queen-dowager, the widow of a king. A queen-consort is in all legal proceedings looked upon as a *feme-sole*, independent of her husband's control, as if she were a single woman. Coke gives as the reason for this that the common law would not have the king, whose care is for public affairs, troubled with the domestic concerns of his wife. The queen-consort has also a particular revenue and peculiar exemptions and privileges. One curious and ancient perquisite is that, when a whale, which is a royal fish, is taken upon the coast, it by right should be divided between the king and the queen, the head only being the king's property, and the tail the queen's. The consort is in all respects a subject of the sovereign; accordingly the husband of a queen-regnant is her subject, and may be guilty of treason against her. Up to the year 1857 the husband of Queen Victoria possessed no distinctive English title, and no place in court ceremonial except such as was conceded to him by courtesy. In that year the title of Prince-Consort was conferred upon him by letters-patent.

Conspiracy, a combination between two or more persons to perpetrate an unlawful act, or to do a lawful act by unlawful means. A person injured by conspiracy has an action at law for the damage done, as when a man is falsely indicted of a crime. In criminal law, conspiracy is a misdemeanour punishable by penal servitude. Few things are left so doubtful in law as the point when a combination for a common object becomes unlawful. Formerly, combinations by workmen to raise the rate of wages were conspiracy, but this is no longer so; and till lately, prevailing judicial opinion was that a trade-union was a 'conspiracy in restraint of trade.' See COMBINATION.

Conspiracy was defined in the reign of Edward I. by the Ordinance of Conspirators, which was aimed at persons binding themselves together to lay false indictments, and otherwise to obstruct the course of justice. But the word came in time to have a wider meaning, and almost every combination to do a criminal or even an unlawful act is now an indictable conspiracy (see COMBINATION). The vagueness of the law has placed considerable power in the hands of juries. Almost any act, however innocent, may be treated as a crime if the jury choose to impute it to some motive connected with

an unlawful combination. Again, in proving a charge of conspiracy, the prosecution may begin by giving evidence of the existence of a general conspiracy, and such evidence may consist of acts of third parties with which the person accused had no connection. The judges also have exercised their own discretion in deciding whether the objects of a combination were 'contrary to good morals and public policy' or not. But if juries and judges have not always exercised their discretion wisely, it is to be remembered that such discretion must of necessity form part of the law of conspiracy. Acts which are comparatively harmless when done by one or two persons may become intolerably oppressive when they are committed by a large number of persons acting in concert. See PLOT, SEDITION.

Conspiracy Bill. See POLITICAL OFFENCES.

Constable (Lat. *constabulus*), the title of an ancient officer, originally of high military rank, but now generally an officer of the peace. The older writers, as Coke and Selden, fancifully derive the word from *konings-stapel*, 'staff and stay of the king.' It represents, however, the Latin *comes stabuli*, 'count of the stable,' an officer who in the later Roman empire was at first charged with the care of the stables, and afterwards became captain of a military force, and chief officer of the army. The title was borrowed from the Romans by the Franks. The Constable of France rose gradually in importance from the comparatively modest position of an officer of the household, till at last he became *ex officio* the commander-in-chief of the army in the absence of the monarch, the highest judge in military offences and in all questions of chivalry and honour, and the supreme regulator and arbitrator in all matters connected with tilts, tournaments, and all martial displays. The office was suppressed by Louis XIII. in 1626. Under Napoleon, the constable was the fifth of the great dignitaries of the empire. The office was again abolished on the restoration of the Bourbons. But besides the Constable of France, almost all the great vassals of the crown had constables who filled analogous offices at their minor courts.

The Lord High Constable of England appears shortly after the Conquest as the seventh great officer of the crown, and formerly a judge in the Court of Chivalry. The office went by inheritance to the Earls of Hereford and Essex, and afterwards in the line of Stafford. When Edward Stafford, Duke of Buckingham, was attainted in 1521, the office became forfeit, and has never since been granted except for a special ceremony of state, as when it was conferred on the Duke of Wellington for the coronation of Queen Victoria. The High Constable of Scotland was an officer very similar to the Constable of France and England. The office, now purely honorary, in 1314 was made hereditary in the noble family of Erroll, and is reserved both in the Treaty of Union and in the statute of George II. abolishing hereditary jurisdictions. The High Constable is by birth the first subject in Scotland after the blood-royal.

The governor of a royal castle was often called Constable; see TOWER OF LONDON. The Constables of the Hundred, and of the Vill, were the predecessors of the high and petty constables of later times. The statute of Winchester (1285) ordains that in every hundred or franchise there shall be chosen two constables, to make the view of armour, and to see to the conservation of the peace. The petty constable exercised similar functions within the narrower limits of the township or parish, and was subordinate to the high constable of the hundred. The high constables were formerly appointed by the

courts leet of the franchise or hundred over which they preside; or, in default of such appointment, by the justices at their special sessions. An act of 1869 made provision for the abolition of the office of high constable throughout England and Wales. The appointment of petty constables is made by the justices, who are directed annually to require from the overseers of parishes a list of those within the parish qualified and liable to serve as constables. When not specially exempted, every able-bodied man, between twenty-five and fifty-five years of age, resident in the parish, and rated to the poor, or a tenant to the value of £4 per annum, must be included in this list. —SPECIAL CONSTABLES are persons sworn in by the justices to preserve the peace, or to execute warrants on special occasions, as in 1848 on account of the Chartists, and in 1887 on account of the 'unemployed' riots in Trafalgar Square, London. Any two justices of the peace who shall learn that a tumult, riot, or felony has taken place, or is apprehended, may swear in as many householders or others as they may think fit, to act as special constables. The lord-lieutenant may also, by direction of one of the principal secretaries of state, cause special constables to be appointed for the whole county, or any part of it. In Scotland, constables are the officers of the justices of the peace charged with the execution of their warrants and orders, and appointed at quarter-sessions. In royal burghs they are appointed by the magistrates. It is their duty, without warrant, to apprehend rioters and breakers of the peace, and bring them before the nearest justice. In the United States they are generally elected by the people, but special constables may be appointed by the authorities in emergencies. The title of High Constable is in some American cities given to the principal police officers. For county constabulary, see POLICE, and for the Irish constabulary, IRELAND.

Constable, ARCHIBALD, publisher, was born at Carnbee, Fife, 24th February 1774, and became a bookseller's apprentice in Edinburgh (1788-95). He then started as a bookseller at the Cross of Edinburgh, and speedily gathered round him the chief book-collectors of the time. He gradually drifted into the publishing business, secured the copyright of the *Scots Magazine* in 1801, and was chosen as the publisher of the afterwards famous *Edinburgh Review*. He published for all the leading men of the time, and his quick appreciation of the merits of the works of Sir Walter Scott became the envy and wonder of the book-trade. There were several business partners in the career of Constable & Co., but Archibald Constable was from first to last the mainspring of the concern. Had painstaking business qualities kept pace with his shrewdness and large-minded literary transactions, business calamities might have been averted. 'Among all his myriad of undertakings, I question,' says Lockhart, 'if any one that really originated with himself, and continued to be superintended by his own care, ever did fail.' In 1812 he purchased for between £13,000 and £14,000 the copyright of the *Encyclopædia Britannica*. In the commercial crisis of 1826 Constable & Co. failed, the liabilities amounting to upwards of a quarter of a million. The only noteworthy publishing scheme of Constable after this failure was the issue of his celebrated *Miscellany*. He died July 21, 1827. See *Archibald Constable and his Literary Correspondents*, by his son, Thomas Constable (1873).

Constable, HENRY, poet, was born in 1562, son of Sir Robert Constable of Newark, a soldier who was knighted by Essex in 1570. At sixteen Henry entered St John's College, Cambridge, early turned Roman Catholic, and betook himself to

Paris. He was pensioned by the French king, and seems to have been often employed in confidential missions to England and to Scotland. He died at Liège, 9th October 1613. In 1592 was published his *Diana*, a collection of twenty-three sonnets; two years later, the second edition, containing seventy-six, but some of these by his devoted friend, Sir Philip Sidney, and other poets. Constable's sonnets are quaint, and sometimes laboured, but they are instinct with fancy and the tremor of genuine poetic feeling. Constable contributed to *England's Helicon* (1600), and sixteen 'spiritual sonnets' to Park's *Heliconia*. See W. C. Hazlitt's edition of his works (1859).

Constable, JOHN, R.A., landscape-painter, was born at East Bergholt, Suffolk, where his father was a well-to-do landowner and miller, 11th June 1776. At the age of eighteen he assisted his father for about a year in the mill; but his love of art was irrepressible, and it was encouraged by Sir George Beaumont, who prevailed upon his family to send him to London. Here he arrived in 1795; and, after an interval of a year spent in his old employment, he returned in 1799, and entered the schools of the Royal Academy, to whose exhibition he sent a work in 1802. Hitherto he had been carefully studying the methods of other painters, poring over Sir George's great Claude, and copying Ruysdael, seeking, as he says, 'truth at second-hand.' He now turned exclusively to nature, resolving to free himself from conventionality, to paint the very fact, to 'adopt a pure and unaffected manner of representing the scenes that may employ me.' But the public, trained to admire an artificial and pseudo-classical adaptation of nature, cared little for his simple renderings of common subjects, and he was nearly forty before he sold a single landscape beyond the circle of his relatives and personal friends. Meanwhile he supported himself by painting likenesses; he copied portraits by Reynolds for the Earl of Dysart, and executed altar-pieces for the churches of Brantham and Nayland in Suffolk.

In 1816 he married Mary Bicknell; and in 1828, on the death of her father, solicitor to the Admiralty, an inheritance of £20,000 placed the family in easy circumstances, and enabled Constable to devote himself quite exclusively to his beloved but unremunerative landscape work. In 1821 he had won the best artistic triumph of his life, in the applause which greeted the appearance of his 'Hay-wain' (then titled 'A Landscape—Noon'), when it was exhibited in the Paris Salon by a French purchaser. Not less marked was the impression produced by his 'White Horse,' at the Lille Exhibition in 1825. Each work gained a gold medal, and the former in particular won the warmest enthusiasm of Delacroix and the other leaders of the romantic school, and exercised a definite and powerful influence upon the future of landscape art in France. Appreciation of this sort was more precious to a true artist than such formal academic honours as Constable won in England, than his election as Associate in 1819, and his tardy and ungraciously awarded promotion to membership in 1829. His later years were saddened by the deaths of his wife and his friend Archdeacon Fisher, by ill-health, and by great depression of spirits; but he worked steadily at his art, though his landscapes still were frequently unsold, producing 'Salisbury Cathedral from the Meadows' (1831); 'Waterloo Bridge,' then titled 'Whitehall Stairs' (1832); and 'The Valley Farm' (1835). He was engaged upon 'Arundel Mill and Castle' at the time of his death, which occurred suddenly, on the 30th of March 1837.

The art of Constable marks the first definite departure in the history of English landscape from the conventional treatment of our earlier painters,

the breaking away from the traditions of Claude and the Dutch masters, the return to direct and personal impressions of nature. With a broad and rapid touch he renders all the force and variety of colouring that full-leaved English landscape presents; catches, with singular skill, her passing effects of rain-cloud and sunlight; suggests, with swift and unsurpassable power, her sense of glitter and motion. Mr Ruskin's criticism has, alike in its general scope and in most of its specific references, done much to disparage Constable's art in the estimation of the public of the time that is just passing; but already there is a recoil on the part of both painters and critics from the detailed intricacy of pre-Raphaelite methods; Constable's works are assuming their true place in the sequence of our national art; and their painter is being recognised as one of the very foremost figures of English landscape-painters. Three of his most important and most powerful landscapes, 'The Valley Farm,' 'The Cornfield,' and 'The Hay-wain,' were already in the National Gallery in 1888, when five more were gifted by the painter's family. His 'Salisbury Cathedral' is at South Kensington, where, as also in the British Museum, his work in water-colour and pencil may be studied.

The most important of the engravings after Constable are the mezzotint plates by David Lucas, many of which were supervised with especial care during their progress by the painter himself. See his Life by C. R. Leslie (1845).

Constance, or KOSTNITZ, a city of Baden, once a free imperial city, is situated on both sides of the Rhine, at its exit from Lake Constance, 91 miles E. of Basel by rail. One of the most ancient towns of Germany, Constance owed its prosperity to its linen industry, for which it was already famous in the 12th century; but five centuries later this had sunk greatly, and it has only been partially revived since the establishment of railways. Its manufactures include linen, cotton, jute, and waterproof fabrics, canvas, carpets, and chemicals; and other industries are bell-founding, printing, and publishing. Beside the picture-gallery, library, and town-hall, with a valuable collection of archives, the most noteworthy buildings are the cathedral (part of which dates from the 11th century), the old Dominican convent (now an hotel), and the present market-hall, in which three places the sessions of the great council were held. Pop. (1885) 14,601.—The most notable event in the history of Constance is the meeting of the ecclesiastical council here in 1414-18 with a view to put an end to the disorders in the papedom and in the election of popes, and also to prevent the spread of the doctrines of Huss. There assembled with the Emperor Sigismund and Pope John XXIII. 3 patriarchs, 33 cardinals, 47 archbishops, 145 bishops, 124 abbots, 750 doctors, and about 18,000 priests and monks, besides numerous princes and counts of the empire, and representatives from all the monarchs of Catholic Christendom; and the retinues of these members of council swelled the number of strangers resident in the town to over 50,000. The three rival popes, John XXIII., Gregory XII., and Benedict XIII., were deposed, and Martin V. was elected. Huss (q.v.) and Jerome of Prague (q.v.) were condemned and burned. The emperor was, however, disappointed in his hope of a thorough reform of the church (*causa reformationis*), in spite of the efforts of such advocates of reform as Peter d'Ailly and Gerson (q.v.); and the Council of Basel (q.v.) was afterwards called to carry on the work which the Council of Constance had failed to accomplish.

Constance, LAKE (called by the Germans *Bodensee* or *Bodmanssee*—the *Lacus Brigantinus*

of the Romans), lies between Switzerland and Germany, and on the north side of the Alps of Switzerland, and forms a meeting-point of the five territories—Baden, Württemberg, Bavaria, Vorarlberg (Austria), and Switzerland. It has an elevation of 1306 feet above the sea. Lake Constance is traversed by the Rhine from east to west; its greatest length is about 44 miles, and utmost breadth 9 miles, the area being 208 sq. miles; the mean depth is 490 feet, while the greatest depth is 906 feet. The southernmost of the two western extremities is called the lower lake, and is separated from the main lake by a narrow channel two miles long, and lies full a yard below the level of the lake. The shores are formed by hilly lands, with low tracts at the mouths of the Rhine and smaller rivers. Cornfields, vineyards, pastures, orchards, and wooded declivities, with here and there the ruins of old castles interspersed, surround the lake. The water has a dark-green hue, often rises suddenly some ten or twelve feet during a thaw, and rolls in high waves during the prevalence of a strong south, north-west, or east wind. Without visible cause it sometimes rises and falls to a considerable degree. Usually the level rises from June onwards to August, when it sinks again. It is seldom frozen, except in very severe winters. The fisheries of this lake are important. Since 1824 steam-navigation has added to the facilities of commerce across the lake, and its commercial importance has been greatly increased by the connection of the chief towns on its shores with the railway systems of South Germany and Switzerland. The most important towns are Constance, Bregenz, Lindau, and Friedrichshafen.

Constans, youngest of the three sons of Constantine the Great, received Illyricum, Italy, and Africa as his share of the empire. After the defeat and death of his elder brother Constantine, in 340 A.D., Constans became sole ruler of the West till his death in 350.

Constant, BENJAMIN, subject-painter, was born in Paris, 10th June 1845. He studied in the École des Beaux-Arts and under Cabanel, and began to exhibit at the Salon in 1869, with his 'Hamlet and the King,' a work purchased by the French government. He soon turned to those Eastern subjects for the treatment of which he is best known, producing 'Prisoners in Morocco' (1875); 'Mahomet II.' (1876); 'The Harem' (1878); 'The Favourite of the Emir' (1879); 'The Day after a Victory in the Alhambra' (1882); and 'The Vengeance of the Chérif' (1885). His works are characterised by direct and powerful but frequently most repulsive realism, melodramatic feeling, bold portrayal of the nude, and vivid colouring. He is one of the most popular of contemporary French painters, and received medals in 1875 and 1876, and the decoration of the Legion of Honour in 1878.

Constant de Rebecque, HENRI BENJAMIN, author and politician, was born of French Huguenot ancestry at Lausanne, 23d October 1767. He was educated at Oxford, Erlangen, and Edinburgh, where he became acquainted with Mackintosh and Erskine. In 1795, settling in Paris, he quickly gained reputation as a publicist. He entered the Tribunate in 1799, but was banished from France in 1802, for having denounced the despotic acts of Napoleon. After travelling over Germany and Italy, in company with Madame de Staël, he lived for a number of years in Göttingen. On Napoleon's fall in 1814 he returned to Paris, and issued several pamphlets advocating constitutional liberty; during the Hundred Days he became one of Napoleon's Councillors of State, though previously he had styled Napoleon a Genghis Khan, and his government a government of Mamelukes. After

the second restoration of the Bourbons, Constant wrote and spoke consistently in favour of constitutional freedom. He was returned to the Chamber of Deputies in 1819, and became the leader of the Opposition. He was the ablest controversialist among the *Doctrinaires*, the French Whigs. The greater number of his very able political pamphlets were collected under the title of *Cours de Politique Constitutionnelle* (4 vols. 1817-20); his *Discours* were published in 1828. He died 8th December 1830. His powerful intellect had many sides. In *De la Religion* (5 vols. 1824-31) he maintained that the spirit of religion, as it grows loftier and purer, casts off the various forms in which it has been embodied, and which obstruct its expansion. He was likewise the author of a remarkable novel, *Adolphe* (1816), a short story of love and disillusion, in which Constant forestalls the method of the modern school of analytic novelists. His Correspondence appeared in 1844, his *Œuvres Politiques* in 1875, and his Letters to Madame Récamier in 1881.

Constantia, a district of Cape Colony, in South Africa, lying on the eastern and north-eastern slopes of Table Mountain range, and distant from Cape Town 7 miles by rail. Constantia consists of only three estates, High, Great, and Little Constantia, which have long been famed for the quality of the wines produced upon them. The wines are sweet wines of delicious aroma, both red and white. For wine-growing at the Cape, see CAPE COLONY, Vol. II. p. 734.

Constantina, a town of Spain, in Andalusia, situated in a mountainous district, 40 miles NNE. of Seville, with silver mines, and a trade in wine and vinegar. Pop. 10,988.

Constantine, capital of the easternmost province of Algeria, is very picturesquely situated on a nearly isolated chalk rock with flat summit, three sides of which are washed by a small stream, flowing through a deep and narrow ravine, and the fourth is connected by a narrow ridge with the adjoining mountains. It is 830 feet above the river, and 2160 feet above the sea; it is connected by rail with its port Philippeville, 40 miles NE., as also with Algiers and with Tunis. It is surrounded by walls constructed by the Arabs out of Roman sculptured stones. There are practically two cities, the French and the Arab, though the running of wide streets through the Arab town has taken away much of its primitive oriental look. Constantine was anciently the capital of Numidia, called *Cirta* by the Carthaginians, *Cirta* by the Romans; and near it many notable events occurred in the wars with Jugurtha. It was destroyed about 311 A.D., but was soon rebuilt by Constantine the Great, from whom it derives its present name. It held out against the Vandals and other besiegers, but was taken by the Arabs in 710. Subsequently, it shared in general the fortunes of Algeria (q.v.). Constantine manufactures woollen cloths, saddlery, leather goods, and carpets; it is a great trade centre, being the chief grain market of Algeria, and exports oil and wool. Pop. (1886) 36,536, of whom 9789 are French and 5780 Jews.

Constantine I., Roman emperor, 306-337 A.D. FLAVIUS VALERIUS AURELIUS CONSTANTINUS, surnamed 'the Great,' was born in 274, at Naissus, in Upper Moesia. He was the eldest son of Constantius Chlorus and Helena, and first distinguished himself as a soldier in Diocletian's famous Egyptian expedition (296), next under Galerius in the Persian war. In 305, the two emperors, Diocletian and Maximian, abdicated, and were succeeded in the supreme rank of Augustus by the two Cæsars, Constantius Chlorus and Galerius. Galerius, envious of young Constantine's

brilliant genius and popularity among the soldiers, took every means of exposing him to danger, and it was now that he acquired that mixture of reserve, cunning, and wisdom, which was so conspicuous in his conduct in after-years. At last, extorting a reluctant consent from the jealous Galerius, he made his way hastily to his father, who ruled in the West, and joined him at Boulogne just as he was setting out on an expedition against the Picts in North Britain (306). Constantius died at York in the same year, having proclaimed his son Constantine his successor. The latter now wrote a conciliatory letter to Galerius, and requested to be acknowledged as Augustus. Galerius did not dare to quarrel with Constantine, yet he granted him the title of Cæsar only. Political complications now increased, until in 308 there were actually no less than six emperors at once—Galerius, Licinius, and Maximin in the East; and Maximian, Maxentius his son, and Constantine in the West. Maxentius having quarrelled with his father, forced him to flee from Rome; he took refuge with Constantine, who had married his daughter Fausta at Arles in 307, but was ungrateful enough to plot the destruction of his benefactor. This being discovered, he fled to Marseilles, the inhabitants of which were just about to give him up to the conqueror, when he anticipated his fate by suicide (309). Maxentius professed great anger at the death of his father, and assembled a large army, with which he threatened Gaul. Constantine anticipated his movements by crossing the Alps by Mont Cénis, and invading Italy. Already twice he had defeated Maxentius, when he finally crushed his power by the great victory of the Milvian Bridge, near Rome, 28th October 312. Maxentius himself was pressed by the thronging crowd of fugitives over the bridge into the river, and drowned. Constantine now entered the capital, disbanded the Praetorian guards, and destroyed their camp. During his short stay in Rome he assumed the title of *Pontifex Maximus*. It was during his final struggle with Maxentius that the famous incident occurred that is said to have caused Constantine's conversion, and which Eusebius gives us an account of from the lips of the emperor himself. At noon there appeared in the sky a flaming cross inscribed 'Εν τούτῳ νικᾷ' ('By this, conquer'). Again, the night before the final battle, a vision appeared to Constantine in his sleep, bidding him inscribe the shields of his soldiers with the sacred monogram of the name of Christ. Hence the well-known *labarum* or standard of the cross, which Constantine, however, did not give his army, according to Gibbon, till 323. Whatever the story of the conversion be worth, one satisfactory consequence was the edict of Milan (March 313), issued conjointly with Licinius, and giving civil rights and toleration to Christians throughout the empire.

Constantine was now sole emperor of the West. Similarly, by the death of Galerius in 311, and of Maximin in 313, Licinius became sole emperor of the East. In 314 a war broke out between the two rulers, in which Licinius had the worst, and was fain to conclude a peace by the cession of Illyricum, Pannonia, and Greece. Constantine gave Licinius his sister Constantina in marriage, and for the next nine years devoted himself vigorously to the correction of abuses in the administration of the laws, to the strengthening of the frontiers of his empire, and to chastising the barbarians, who learned to fear and respect his power. In 323 he renewed the war with Licinius, whom he defeated, and ultimately put to death. Constantine was now at the summit of his ambition, the sole governor of the Roman world. He chose Byzantium for his capital, and in 330 solemnly inaugurated it as the seat of

government, under the name of Constantinople or City of Constantine. In 324 he committed a deed that has thrown a dark shade over his memory. He had a gallant and accomplished son named Crispus, who was exceedingly popular, and him, along with Constantina and others, he put to death on a charge of treason. Niebuhr shows that it was not unlikely Crispus cherished ambitious designs. Next year occurred the great Council of Nicæa, in which he opposed the Arians on political grounds, as the weaker party; but not being theologically interested in the dissensions, refrained from active persecution of them. During the later years of his life, Christianity became the state religion, the pagan temples were closed, and sacrifices forbidden. Yet it was only a short time before his death, which occurred 22d July 337, that he would allow himself to be baptised by the Arian bishop, Eusebius of Nicomedia. The story of his baptism at Rome by Pope Sylvester in 326, and of the so-called *Donation of Constantine* thereafter, alluded to in Dante's *Inferno*, and often in the past gravely argued as giving an historical basis for the temporal power of the papacy, may safely be dismissed (see CANON LAW). For other Constantines, see BYZANTINE EMPIRE.

Constantine Nikolaevitch, Grand-duke of Russia, the second son of the emperor Nicholas I., and the brother of Alexander II., was born 21st September 1827. During the Crimean war he commanded the Russian fleet in the Baltic, and directed the defensive preparations which held the English and French armaments in check before Cronstadt. The leader of the Muscovite or national party, he strenuously opposed the concessions made to the western powers, but throughout gave, although contrary to expectation, steady allegiance to his elder brother from his accession to his unhappy death. On the outbreak of the Polish insurrection in 1862, he held the office of viceroy of Poland for three months, was appointed in January 1865 and reappointed in 1878 president of the council of the empire. In 1882 he was dismissed from this dignity, as well as the command of the fleet, on the suspicion of having intrigued with the revolutionary party, while his eldest son, Nicholas, was banished to Tashkent.

Constantinople, 49° N. lat., 28° 59' E. long., the capital of the Ottoman empire, was founded in 330 A.D. by Constantine the Great, from whom it derives its name, on a site partly occupied by the ancient Byzantium. The Turks call it *Istambul* or *Stambul*, which they pretend is a corruption of *Islambol* ('Islam abounding'), a name which was formerly engraved upon the coinage in lieu of *Konstantinufya*, the Arabic form of *Constantinopolis*. European writers have fancifully derived *Istambul* from the Greek expression *εἰς τὴν πόλιν*, 'up to town,' but a more probable derivation makes it simply a Turkish mispronunciation of *Constantinopolis*. The original Byzantium was a colony (about 658 B.C.) from Megara, with an Argive mixture, however, to which the worship of Hera, and the introduction of the myth of Io, represented upon the earliest coins, may probably be ascribed. It was built on the apex of the triangular peninsula which juts out towards Asia on the southern side of the Golden Horn, where the present Eski Serai or 'Old Seraglio' stands, and its commanding position made it an object of strife among the nations—Persians, Gauls, and Greeks. In the middle of the 4th century B.C., the Athenians under Demosthenes, coming to the assistance of the Byzantines, repelled the siege of Philip of Macedon, aided, according to the legend, by the supernatural appearance of a crescent in the sky, which revealed the presence of the invaders, and

was forthwith adopted as the badge or crest of the city, as it is to this day. After its submission, the Roman emperors long recognised its virtual independence, and in 330 A.D., impressed by its magnificent site, Constantine the Great abandoned the old capital on the Tiber, and founded in the place of Byzantium a new metropolis on the Bosphorus, which he called Constantinople. Its walls and public buildings were enlarged and beautified by Justinian in 527-65. Since then it has undergone many sieges by Sassanians, Persians, Avars, Saracens (six times), Russians (in 9th to 11th century), Latins, and Turks; and of its twenty-six sieges and eight captures, that of the Latins under Baldwin and Dandolo in 1204 was by far the most disastrous, barbarous, and spoliating. The chief adornments of the city, the treasures of the churches, and even the bodies of the great dead, were not respected by these vandal 'crusaders.' In comparison, the Turkish sieges were humane and chivalrous: the first took place in 1356; Murâd II. made the

attempt again in 1422; and Mohammed II. carried the city against the resolute resistance of Constantine Palæologus and Justiniani in 1453. Since then, such has been the renown of the Turks or the jealousy of the Powers, that the imperial city has witnessed no fresh siege (see TURKEY).

Constantinople consists of two distinct parts, besides more distant suburbs—Constantinople proper or *Stambul*, and what may be termed Christian Constantinople (Pera, Galata, Top-hana), because it is there that the Christian colonies chiefly congregate. The two are separated by the Golden Horn, a creek about five miles long and half a mile wide at the entrance, so called probably from its famous fisheries, a veritable horn of plenty

to the ancient inhabitants; in the present day a safe harbour, capable of accommodating 1200 sail, and so deep that the largest ironclads of the Turkish navy, which may be seen there during a great part of the year, find enough water for their draught quite close to the shore. Stambol or Turkish Constantinople lies on the southern side of the Golden Horn, and Christian Constantinople lies on the north side: the two are connected by a couple of rude but convenient bridges, from the larger of which steamers start for various points on the Bosphorus and Sea of Marmora. Stambol is on the site of Byzantium, and the old walls, in courses of stone and red brick, which Constantine built and Theodosius and others restored, show that the modern Turkish city occupies much the same area as the capital of the first Christian emperor. The walls run a circuit of 14 miles from the grim but now ruined and disused castle of the Seven Towers—where many sultans met their deaths at the hands of their mutinous soldiery, and where foreign ambassadors were imprisoned upon declaration of war—to the Golden Horn, then along its southern shore to Seraglio Point, and so back to the Seven Towers close along the margin of the Propontis. Within these walls the city rises, like Rome, upon seven low hills, crowned by noble mosques, with a wilderness of picturesque, tumble-down, filthy, wooden houses, and lane upon lane of even more picturesque and scarcely less dirty bazaars, climbing up their sides from the Golden Horn to the Hippodrome. Years ago Stambol was more beautiful and more filthy, but fire, the great purifier of the East, has so repeatedly laid low its thousands of dwellings, that the old streets are becoming few, and their place is being taken by more sanitary but not equally pleasing thoroughfares and brick or stone houses. In the bazaars and some of the less reformed byways there is quite enough of the old Mussulman leaven to make one's eye and one's nose aware of the charms and the drawbacks of an oriental city. Very few of the goods, however, which the admiring tourist carries away from the bazaars are made there; many come from Vienna, and not a few from Manchester, whither they are faithfully brought back by the travelled citizen.

In Stambol are nearly all the monuments and antiquities worth seeing in Constantinople. In the row of some half-dozen mosques, whose conglomeration of domes, like a clustered jelly-mould, and tall and exceedingly slender minarets, crown the summits of the hills, we see some of the most famous and magnificent monuments of Christian and Saracenic art. First, next the Seraglio, stands Agia Sophia, Saint Sophia, the church dedicated by Constantine to 'Eternal Wisdom,' and rebuilt with added splendour by Theodosius (415) and by Justinian (538-568), and now converted into a cathedral mosque. Outside it is not worth a second glance; but within, the airy grace of its stupendous dome, and the beauty of its marbles and mosaics, despite all the ravages of Moslem, and, worse than Moslem, tourists' desecrations, fascinate and amaze the vision (see *BYZANTINE ARCHITECTURE*). Next, but not less beautiful, is the Suleymaniya, the mosque which the Great Suleyman and his architect Sinan erected in 1550-5 on the model of St Sophia, but with Saracenic ornament and a loftier though not quite so expansive dome. Some of the monolithic columns are remarkable for their size and beauty, and the general effect is even more imposing than that of St Sophia. Scarcely less stately is the mosque of Sultan Ahmed I. in the Hippodrome; distinguished without by its six minarets (instead of the usual four), and within by the four gigantic columns, 36 yards round, which support

the dome: here the official celebrations and formal processions take place at the great festivals. The mosque of the conqueror Mohammed II. is also worth seeing, though it has been greatly altered in restoration. There are over two hundred other mosques in Constantinople, and an even larger number of chapels (besides hundreds of *medreses* or mosque colleges, and *mektebs* or elementary schools); but very few of them present features of special interest, except sometimes in the beauty of their wall tiles, of the Rhodian style, for the manufacture of which the suburb of Eyyûb was famous.

The remains of the Greek churches are more interesting, and the Fanar, or Greek quarter of Stambol, recall the memories of many distinguished Fanariote statesmen; but among the relics of ancient Constantinople none is more striking than the Hippodrome (now called At-Meydan, or 'Horse Manège'), originally a circus surrounded by marble seats, long since removed, but still showing remains of antiquity, such as the famous column of the Three Serpents which once stood at the Temple of Delphi, and supported a gold tripod made out of the spoils taken by the Greeks at the battle of Plataea, but was removed to his new capital by Constantine. The serpents' heads are broken off; one was said to have been struck off by the scimitar of Mohammed the Conqueror, and one is still preserved in the museum of antiquities. In the Hippodrome also stands an obelisk brought from On (Heliopolis) in Egypt, and re-erected by Proclus the Praetor in the reign of Theodosius; hard by are the Burnt Column, the column of Theodosius, and the Seraskier's Tower, whence watchmen survey the city and give warning of conflagrations. Among the remains of Mohammedan splendour the Old Seraglio (Eski Serai) is the most important, though it has not been a royal residence since the days of Mahmûd II. Its first gate, Bab-i-Humayûn or 'Sublime Porte,' has given its name to the Turkish government in its foreign relations. Within its three spacious courts, full of beautiful trees and picturesque in their gray decay, are various stables and offices of the court, the old council chamber, the armoury (once the Church of St Irene), the museum, mint, and the celebrated treasury, where uncut jewels, gold-embroidered vestments, and gorgeously mounted arms are preserved in fabulous value. In the neglected gardens overlooking Seraglio Point, whence a lovely view is gained of the Bosphorus, the Asiatic shore, and the Sea of Marmora, are various kiosks, one of which, called that of Baghdad or Murâd IV., is lined with exquisite tiles, another contains the imperial library, and a third is the ominous Kafes or 'cage' where the unhappy princes who menaced the peace of sultans were immured for all their lives.

Christian Constantinople, on the north side of the Golden Horn, comprises Galata, Pera, and Top-hâna. Galata is pre-eminently the merchant quarter, the seat of customs, and the steam companies' agencies; it was founded by a colony of Genoese merchants in 1216, and originally was inclosed by walls of 4 miles' circuit, now destroyed. Traces of Genoese architecture may still be found in the narrow dirty streets, and in the Tower of Galata, a Genoese erection, which serves the same purpose as the Seraskier's Tower on the opposite side in giving alarms of fires. Of late years Galata has been considerably improved; stone and brick houses have superseded the dangerous wooden constructions of the past; a good thoroughfare provided with a tramway extends for a mile to Beshiktâsh, and a tunnelled railway drags passengers up the steep ascent to Pera. Pera is the aristocratic quarter; here are all the embassies and legations and consulates, and here every one of position has his town-house. Two-thirds of

this quarter were burned down in 1870, including the English embassy, and 40,000 persons were left homeless. The result was a considerable improvement in the architecture and ventilation of Pera. The steep and badly paved Grande Rue, which traverses the whole quarter, and is continued along the shore of the Bosphorus for many miles, is, however, still in parts little better than a lane; but it is lined with fair if expensive shops, and boasts a rude opera-house, many cafés and restaurants, besides most of the principal hotels, and probably the worst morals in Europe. In Pera is the English Memorial Church, erected in honour of those who fell in the Crimean war. Turks preponderate at Top-hâna, which is so named from its cannon-foundry, and is chiefly famous for its market, its Circassian slave-dealers, its café-building, and its beautiful marble fountain. Close by is the magnificent palace of Dolmabahçhé, on the brink of the Bosphorus.

Among the other suburbs may be mentioned Kâsım Pasha, extending beyond Galata, along the north shore of the Golden Horn, the seat of the admiralty; continued by Hasköi, inhabited by a Jewish and Armenian colony; and at the head of the Golden Horn the picturesque village of Eyyûb, a green medley of gardens and graveyards surrounding the celebrated mosque where every sultan must gird on the sword of Osman ere he may ascend the throne. No Christian is allowed to approach the holy place. Along the European shore of the Bosphorus are many villages used as summer resorts by the Perotes, among which Therapia, the chief summer residence of the ambassadors, and Biyukderé are the most important. The Asiatic shore is also lined with settlements, from Scutari, which is the Asiatic suburb of Stambol (where is the chief Turkish burial-place, as well as the great Crimean cemetery), to Candili, where is a large European population, chiefly of the trading classes, and Beikos (see BOSPORUS). Numerous palaces of past sultans and ministers line both shores, Dolmabahçhé on the European and Beglerbeg on the Asiatic being the largest; but the present sultan resides in a new palace called Yıldız Köshki, at the top of the hill of Beshiktâsh, beyond Pera. Famous among pleasure resorts are the Sweet Waters of Europe, at the head of the Golden Horn; Kınhat-hâna, near the Castle of Asia; the forest of Belgrade; and the Princes' Islands in the Sea of Marmora, not far from Kadiköi, the ancient Chalcedon.—The population of Constantinople is estimated at about 875,000, of whom half are Mohammedans. The trade, chiefly in the hands of Europeans, is increasing, but much below what it might be if properly developed. The local manufactures are insignificant. The burden of vessels entering and clearing the port is placed at 4,000,000 tons. The strategical importance of Constantinople induced an English officer to superintend the erection of fortified lines on the land side, from Biyukçekmeji on the Sea of Marmora to Lake Derkos on the Black Sea, a distance of about 20 miles. The first through express train from Western Europe, inaugurating a direct service with Paris, reached Stambol station on 10th November 1888. Railways also connect Constantinople with Adrianople and Belgrade, and Salonika and Uskub; and there is another line from Smyrna to Aydin.—For the Councils of Constantinople (381 and 553 A.D.), see COUNCILS.

Constantius Chlorus, nephew of the emperor Claudius II., became Cæsar in 292 A.D., received Britain, Gaul, and Spain as his government, and after re-establishing Roman power in Britain and defeating the Alemanni, became one

of the two Augustuses in 305, but died at York in 306. Constantine the Great was his son.—(2) **CONSTANTIUS**, third son of Constantine, was Roman emperor, 337-361 A.D. He fought with the Persians; and after the death in 350 of his brother Constans (who in 340 had defeated their elder brother Constantine), became sole emperor till his death in 361.

Constanza. See KUSTENDJI.

Constellation (Lat. *con*, 'together,' and *stella*, 'a star'), a group of stars. The stars which stud the firmament have, from a time earlier than authentic records can trace, been formed into artificial groups, which have received names borrowed from fancy or fable, mainly from Greek mythology. These groups are called constellations. Though quite devoid of anything like systematic arrangement, this traditional grouping is found a sufficiently convenient classification, and still remains the basis of nomenclature for the stars among astronomers. They are divided into northern, southern, and zodiacal constellations. In old authors, 'constellation' is used to signify the relative positions of the planets (see ASPECTS) at a given moment. See STAR, ORION, Ursa Major, ZODIAC.

Constipation, or irregular and insufficient action of the bowels, is one of the most common of ailments; there are few persons in fact who have not at some time or other suffered from it. It may be due either to deficient secretion of fluids in the digestive organs, or to imperfect muscular action of the bowels (see DIGESTION), or most often to both these causes combined. The retention within the organism of matters which should be regularly evacuated as they are formed, and their consequent absorption into the blood and tissues of the body, often leads to a whole train of unpleasant symptoms: headache, or pain in other regions, irritability, lassitude, and debility, and many other discomforts may be due to this cause. In prolonged and severe cases of constipation, actual obstruction of the bowels (*ileus*) may result; and often the bowel becomes so distended and its muscular power so enfeebled that the restoration of a healthy condition is impossible.

Constipation is especially apt to occur in those who lead sedentary lives, or whose diet consists too exclusively of animal food and starchy substances. It may often be avoided by judicious regulation of habits and diet; and the hygienic treatment is of far more importance than the medicinal.

In perfect health, the lower bowel should be evacuated every day, or at the furthest every second day. This process, like many others in the body, tends to recur at the same period every day, and every one should do all he can to acquire a habit of regularity in this respect. Moderate regular exercise, especially in the open air, is often of great importance; where the liver is at fault, riding is specially useful. A daily cold bath, or in the case of those with whom this does not agree, brisk rubbing with a rough towel, may be helpful. A favourite remedy with some is the use of a cloth wrung out of cold or tepid water and applied to the abdomen; this, as used at hydropathic establishments, is called an 'abdominal compress,' and is worn under a bandage of macintosh cloth, to keep the moisture from escaping, during the earlier part of the day.

Attention to diet is of prime importance. In Britain very many persons live almost entirely on animal food, white bread, and potatoes, a diet extremely apt to lead to constipation. There are many easily obtainable foods the habitual use of which would in many cases correct this tendency. Oatmeal, especially in the form of porridge, brown

or 'whole-meal' bread, or gingerbread; almost all vegetables (except potatoes), either cooked or uncooked; olive-oil, which may be used in salads; treacle, eaten with bread or made into puddings; fruit of all kinds, particularly prunes and figs, which can be obtained all the year round—all tend to increase the activity of the bowels. If such forms of food were more generally used, the rest of the community would gain even more than the many vendors of 'liver pills,' and other quack medicines would lose.

The amount of fluid taken in the day is also of importance. Many persons, especially those in whom much fluid taken with meals interferes with comfortable digestion, do not imbibe enough for the needs of the body. In such cases a stated amount of fluid should be taken at other times. A tumbler of water, either cold or hot, slowly sipped during the process of dressing in the morning, is sometimes efficient in relieving constipation.

Lastly, the use of medicinal remedies must be shortly considered. Compared with the measures already noticed, they must be regarded as an evil, though often a necessary one. Constipation may be seriously aggravated by their injudicious employment. Often a large dose of some purgative is taken and produces very free action of the bowels with temporary relief; but increased constipation is almost sure to follow. The condition to be remedied is a chronic and habitual one, and must be combated by patient and persevering treatment. The medicine selected should be taken every day, but the dose must be the very smallest which will produce the desired effect.

It is impossible to enumerate all the drugs which may be used, or to define the conditions in which each is most likely to be beneficial. A few of those in most general use only must be enumerated. Natural mineral-waters (Friedrichshall, &c.) are in much repute at present: a dose should be taken on rising in the morning. Epsom or Glauber's salt, if dissolved in plenty of water, is much cheaper and almost as satisfactory. Effervescent salines (seidlitz powder, magnesia, and many much-advertised patent medicines) are more pleasant to take, and have a similar action. Castor-oil in small doses at bedtime is objectionable only on account of its flavour. Compound colocynth pills, or colocynth and hyoscyamus pills; compound liquorice powder (containing senna and sulphur, one of the best preparations); Gregory's powder (containing rhubarb and magnesia); podophyllin, euonymin, and other drugs from America, are all useful aperients, and should be taken at bedtime. Nuxvomica is a useful addition to other aperients, as it acts specially upon the muscles of the intestines, increasing their activity. A word of caution is necessary regarding mercurial preparations, which are most valuable in certain cases, but most dangerous if used habitually. The indiscriminate use of calomel and gray powder in the nursery, where they are very popular owing to their tastelessness, cannot too strongly be condemned. The most generally useful of all aperients at present in use is *Cascara Sagrada*, the bark of a North American species of buckthorn (*Rhamnus Purshiana*). The liquid extract is the preparation in most general use, of which from 15 to 40 drops taken daily, either in one dose at bedtime or still better in several doses after meals, is generally sufficient. It increases the secretions, but especially the muscular power of the intestine; and in very many cases can be given up altogether after being used for a few weeks (see also **APERIENTS**). In some cases Clysters (q.v.) are the most satisfactory means of procuring an evacuation.

Constipation in the lower animals depends, as in man, on imperfect secretion from, or motion of, the intestinal walls. In the horse it is usually accom-

panied by Colic (q.v.), and when long continued leads to Enteritis (q.v.). The appropriate remedies are soap and water clysters given every two hours; smart friction and cloths wrung out of hot water applied to the abdomen, with three drachms of aloes and one of calomel given in gruel, and repeated in sixteen hours, if no effect is produced. Give, besides, walking exercise; restrict the amount of dry solid food, but allow plenty of thin gruel or other fluids, which may be rendered more laxative by admixture with treacle or a little salt. Similar treatment is called for in dogs, cats, and pigs.

In cattle and sheep, digestion principally takes place in the large and quadrisected stomach; the bowels, accordingly, are little liable to derangement; and constipation, when occurring in these animals, generally depends upon impaction of dry hard food between the leaves of the third stomach, fardel-bag, or moniplies. The complaint is hence called *fardel-bound*. It results from the eating of tough and indigestible food, such as ripe vetches, ryegrass, or clover; it prevails in dry seasons, and on pastures where the herbage is coarse and the water scarce. It occurs amongst cattle eating freely of hedge-cuttings or shoots of trees, hence its synonym *wood-eil*. From continuous cramming and want of exercise, it is frequent in stall-feeding animals; whilst from the drying up of the natural secretions, it accompanies most febrile and inflammatory diseases. The milder cases constitute the ordinary form of indigestion in ruminants, are accompanied by what the cow-man terms *loss of cud*, and usually yield to a dose of salts given with an ounce or two of ginger. In more protracted cases, rumination is suspended, appetite gone, constipation and fever are present. There is a grunt noticeable, especially when the animal is moved, different from that accompanying chest complaints, by its occurrence at the commencement of expiration. By pressing the closed fist upwards and forwards beneath the short ribs on the right side, the round, hard, distended stomach may be felt. This state of matters may continue for ten days or a fortnight, when the animal, if unrelieved, becomes nauseated, and sinks. Stupor sometimes precedes death, whilst in some seasons and localities most of the bad cases are accompanied by excitement and frenzy. In this, as in other respects, the disease closely corresponds with stomach-staggers in the horse.

Give purgatives in large doses, combining several together, and administering them with stimulants in plenty of fluid. For a medium-sized ox or cow, use $\frac{3}{4}$ lb. each of common and Epsom salts, ten croton beans, and a drachm of calomel, with three ounces of turpentine; and administer this in half a gallon of water. If no effect is produced in twenty hours, repeat the dose. Withhold all solid food; encourage the animal to drink gruel, sloppy mashies, treacle and water; and give exercise, clysters, and occasional fomentations to the belly.

Constitution, in Politics, signifies a system of law established by the sovereign power of a state for its own guidance. Its main objects are to fix the limits and define the relations of the legislative, the judicial, and the executive powers of the state, both amongst themselves and with reference to the citizens of the state, regarded as a governed body. In continental countries, since the formation of the federal government of the United States of America, or, at all events, since the first French Revolution, the idea of a constitution has been generally that of a body of written public law, promulgated at once by the sovereign power. In Great Britain it is the whole body of the public law, consuetudinary as well as statutory, which has grown up during the course of ages, and is continually being modified by the action of the general will as interpreted and expressed by the

parliamentary representatives of the nation. A constitutional monarchy is one in which the sovereign is restricted in his powers by chambers of the representatives of the people; the 'granting of a constitution' accordingly means the transforming of a monarchy more or less nearly absolute into a constitutional state. The constitutions of the various countries will be found under ENGLAND, UNITED STATES, FRANCE, GERMANY, &c., as also at PARLIAMENT, CONGRESS, GOVERNMENT, &c.

Constitutions, APOSTOLIC. See APOSTOLIC CONSTITUTIONS.

Consubstantiation, as opposed to Transubstantiation (q.v.), is the Lutheran doctrine that in the eucharist the body and blood of Christ are, in a way not to be explained, in, with, and under the unchanged bread and wine. See LORD'S SUPPER.

Consuetudinary or CUSTOMARY LAW is an unwritten law established by usage and derived by immemorial custom from remote antiquity. When universal, it is called common law; when particular, it is called custom in a narrower sense, as the custom of a trade or of a district. See CUSTOM, COMMON LAW.

Consul, the title of the two highest ordinary magistrates in the Roman republic. The idea of two supreme magistrates or joint-presidents of the state seems to have been interwoven with the earliest conceptions of political organisation in Rome. After the expulsion of Tarquin, Lucius Junius Brutus and Lucius Tarquinius Collatinus were chosen joint heads of the state; but the title of *consules* seems first to have been introduced about 300 B.C. At first, the consuls seem to have differed from the kings in little else than their limited tenure of office, and the power which their fellow-citizens retained of calling them to account at its termination. They never assumed the golden crown, but their dress in almost every other respect was regal. They made peace and negotiated foreign alliances, had the supreme command of the army, and appointed the public treasurers. They likewise exercised the judicial functions of royalty. Dates were always determined by naming the consuls of the year. The symbol of their authority was the bundle of rods (*fusces*), with the axe in the centre, which was carried before them by twelve lictors. For a considerable period the consuls were chosen exclusively from the *populus* or patricians, as opposed to the *plebs*. At length, however, two plebeian officers called *tribuni plebis* were appointed as a sort of democratic rivals to the aristocratic consuls. The result of this rivalry was that the consulship was opened to plebeians, the famous *Lex Licinia* (367 B.C.) ordaining that one of the consuls should belong to that order. This law was more stringently re-enacted in 342, and from that time it was customary for one of the consuls to be a plebeian. This same law prohibited any individual from holding the same office within ten years, but the enactment was often suspended. The appointment of *Censores* (443) and of *Prætores* (367) relieved the consuls of many of their judicial functions. In the government of the provinces, the aid of the former consuls was called in, the consul thus appointed having the title of *pro-consul*. In sudden and critical emergencies, the consuls were either superseded by a Dictator (q.v.), or absolute power for the occasion was conferred on them by the decree of the senate, which ran in the famous formula: *Videant consules ne quid respublica detrimenti capiat*—'Let the consuls look to it that the state take no harm.' The consuls were inaugurated by a great procession to the Capitol and a sacrifice to Jupiter Capitolinus. The shadow of the consulate survived the downfall of liberty;

but the election of the consuls was taken from the people and conferred on the senate. Then their number was increased; they were divided into classes; till at last the office became, a mere honorary appointment conferred by the emperor.

The title of consul was revived in the French republic after the revolution of the 18th Brumaire, and lasted till the coronation of Napoleon as emperor, 18th May 1804.

Consul, MERCANTILE, the name given to those officers whom the state maintains in foreign countries for the protection of its trade and vindication of the rights of its merchants, and to whom the further duty is assigned of keeping the home government informed of all facts bearing on the commercial interests of the country. The practice of appointing such officers originated among the trading communities of Italy about the middle of the 12th century, and gradually extended itself; and in the 16th century had been adopted by all the countries of Europe. In addition to their commercial duties, others of a more strictly political kind were frequently confided to consuls in places in which there was no ambassador or political agent. In almost all the countries of Europe, consuls are divided into consuls-general, consuls, vice-consuls, and consular agents. The consul's first duty on his arrival is to exhibit his commission to the authorities of the country to which he is accredited, in order that he may obtain their sanction to his appointment. This sanction is communicated to him in a document called an *exequatur*, which secures to him the enjoyment of such 'privileges, immunities, and exemptions as have been enjoyed by his predecessors, and as are usually granted to consuls in the country in which he is to reside.'

The general duties of English consuls are communicated to them in printed instructions. In these the consul is ordered to make himself conversant with the laws and general principles which relate to the trade of Great Britain with foreign parts, and with the language and municipal laws of the country wherein he resides. Further, it is his duty to protect his countrymen in the lawful exercise of their trade, to quiet their differences, to obtain the redress of injuries done them—failing which, to report the matter to the English ambassador at the capital of the country—and to forward to the Secretary of State for Foreign Affairs an annual return of the trade carried on at the different ports within his consulate, as well as a quarterly account of the market prices of agricultural produce during each week of the quarter, the course of exchange, &c. The consul must afford relief to British seamen or other subjects wrecked on the coast, and endeavour to procure them the means of returning to England. The commanders of British war-ships touching on the coast are entitled to call on him for intelligence, and aid in procuring supplies of water, provisions, and the like; and it is his duty to endeavour to recover all wrecks and stores, &c. of queen's ships, whether found at sea and brought into the port at which he resides, or thrown on the coast. As regards his 'privileges and immunities,' a consul engaged in trade is amenable to the civil jurisdiction of the state to which he is accredited, but a consul sent out from this country, and not engaging in trade, has always been exempted from the taxes of the country in which he resides. A consul can perform all the acts of a notary-public, all deeds executed by him being acknowledged as valid by our courts of law. The fiction is, that the consulate is the territory of the country from which the consul is sent, and, consequently, that deeds and acts done within it, or under the consul's seal, are done in England. Hence the

marriage of British subjects recorded in the books of a British consul is a valid ceremony.

Consuls in the Levant, China, Japan, and other places have special powers and privileges granted to them and regulated by what are called capitulations. They act as judges in consular courts to whose jurisdiction all subjects of their nation are amenable, to the exclusion of the native tribunals. By orders in council in force January 1, 1888, special privileges of this nature are enjoyed by English consuls in South Africa, west coast of Africa, China, Corea, Egypt, Japan, Madagascar, Morocco, Muscat, Siam, Tripoli, Turkey, the Western Pacific, and Zanzibar.

The first care of every Levantine trader is to obtain the protection of some foreign power, so that he may set at defiance the local courts, and, to some extent, the local executive authority. To obtain letters of nationalisation as a British subject is rightly made somewhat difficult; but this is not the case with most other European nations. The capitulations are especially injurious in Egypt, where the native authorities and their English advisers are constantly thwarted in their endeavours to promote order and good government by the ill-defined and jealously-asserted power of the foreign consuls.

Of late years attempts have been made to establish a body of trained men from among whom the consular service in the Levant, as well as in China and Japan, could be recruited, and student interpreterships have been founded. The student interpreters are selected by competitive examination in England, and are sent to Constantinople or to the far East, as the case may be, with a salary of £200 a year. Their advancement 'depends entirely on the ability which they may show after their arrival at their destination, and on their general steadiness and good conduct.'

Consuls who are permitted to trade are not required to pass any examination, but members of what may be called the regular service are supposed to do so. The limit of age for appointments is twenty-five to fifty.

In the United States, literary and scientific men are frequently appointed to important consulships abroad, Hawthorne and Bret Harte having, for example, been consuls in Britain. In the British service the names of Charles Lever, Mr Stigand, Gifford Palgrave, and Sir Richard Burton are modern examples of such appointments.

The salary of British consuls varies from £2500 (chief-justice of the Supreme Court for China and Japan), to the nominal salary of many vice-consuls. Among the more important posts are the consul-general at Shanghai, £1600; consul-general at New York, £2000; consul at Boston, £1200; New Orleans, £1100; Zanzibar, £2150; Honolulu, £1100; Sofia, £1200; Beyrout, £1250; Manila, £1100; Old Calabar, £1200; the consul-general and judge at Constantinople, £1600. The United States consuls at London, Liverpool, Paris, Rio Janeiro, and Havana have each, apart from fees, a salary of \$6000.

Consumption, in Political Economy, is that department of the subject which treats of the use of wealth. It is the converse of production, which refers to the making or creating of wealth. As production is the first stage in economics, consumption is the last. Consumption is the chief end of industry, for everything that is produced and exchanged is intended in some way to be consumed. Consumption is usually divided into two heads—reproductive and non-reproductive. Wealth consumed in reproduction is simply Capital (q.v.). Wealth consumed as capital, while it is the final stage in one process of industry, becomes an item in a further process of industry. A shopkeeper who,

having made a thousand pounds in his business, afterwards uses it in farming, proposes thereby to apply his money to a new kind of reproductive employment. Industry is to a large degree simply a continuation of this process. Wealth which is produced to-day will to-morrow be consumed in fresh production.

But consumption is perhaps more properly regarded as non-reproductive, as that use of wealth which has no fresh production in view, or is simply applied to the satisfaction of human needs. The wants of men, as well as the means of satisfying them, have varied greatly at different periods of history, and do still greatly vary in different countries and different states of society. As regards wealth applied to consumption, we may recognise three stages: (1) Necessaries; (2) comforts; (3) luxuries. The commodities which were once a luxury are now in civilised countries merely a comfort or even a necessity. In the middle ages a linen shirt was a luxury even at royal courts. In fact, nothing perhaps so marks the development of comfort as the general use of underclothing, whether woollen, cotton, or linen. In the economics of all ages the question of luxury has claimed great attention. The extravagance of the wealthy was both in ancient and medieval times considered so dangerous to society, that Sumptuary Laws (q.v.) were passed to repress it, often without the desired effect. On the other hand, the luxury, extravagance, and even prodigality of the rich have been justified on the ground that such expenditure was necessary to provide labour for the industrial classes; but this notion is exploded among competent economists. It should be clearly understood that consumption should be both rational and moral, and that the just and rational needs of men have the first claim on society.

As all wealth is produced in order to be consumed, and as there can be no consumption without production, it will be obvious how the great processes of production and consumption are correlated to each other. If there be insufficient production, consumption is checked and suffering ensues through human wants not being satisfied. On the other hand, over-production frequently tends to bring about commercial crises. When the effective consumption is unable to absorb the mass of commodities, the market becomes overstocked and the industrial process is deranged.

Consumption, DECLINE (in medical language, Phthisis, Tuberculosis), is a condition well recognised by the laity as by the physician. Strictly speaking, the name includes a group of affections, but it is generally used to indicate pulmonary consumption (*phthisis pulmonalis*)—i.e. a more or less rapidly advancing process of lung destruction, associated with progressive emaciation and other characteristic signs and symptoms. This is a disease of grave importance, from its frequency and fatal tendency. It has been estimated that consumption is responsible for nearly one-seventh of the total mortality of Europe. Consumption appears to have committed its ravages from the earliest times, and its distribution is probably universal, though far from equal. Thus, statistics show consumption to be less common in the Hebrides and Shetland Islands than on the mainland of Scotland, while the unanimous verdict of Icelandic physicians has been that consumption occurs relatively seldom in their island. It is not easy to propose any fixed rule regarding its distribution. Latitude as such seems of less importance than might be expected. The mean level of temperature has little connection with its occurrence, though apparently, in tropical countries, the course of the disease is more rapid. The most probable explanation of the comparative immunity of certain

districts and countries is to be found rather in the minimal amount of moisture present. Wetness of the soil is a factor of the greatest importance, as was shown by the researches of Bowditch in America, Buchanan in England, and Milroy in Scotland. Their united testimony was that the number of cases of consumption varied directly with the degree of dampness of the soil. Elevation also exercises an important influence; and, other things being equal, the more elevated the district, the less favourable will it be to the occurrence of consumption. The explanation of this is probably to be found in the combined purity and rarity of the atmosphere.

Though consumption was early recognised as a definite disease, and its clinical course fairly well studied, much obscurity has rested over the question of its causation. About no disease has opinion so persistently fluctuated. Definition was first rigidly attempted by Bayle and Laennec, who held that consumption was essentially due to the presence in the lung of little granular masses of varying size and character, which were named Tubercle (q.v.). On the other hand, Andral, Virchow, and Niemeyer maintained that only a limited number of cases were to be so explained, and that consumption was most frequently induced by a process of chronic inflammation of the lung. This view gave scientific basis to the popular belief in the effects of neglected cold. Medical opinion was divided between those main lines until 1882, when Koch announced the fact that he had discovered an organism, which he believed to be present in all cases of consumption proper. This organism—the *Bacillus tuberculosis*—is a minute rod-like structure, capable of cultivation outside the human body, and easy of demonstration in the expectoration of consumptive patients (see BACTERIA). Clinical and experimental evidence has since corroborated the truth of Koch's assertions, and the bacillar origin of consumption has been pretty generally accepted, so that the older teaching has been subjected to much modification. Although this is so, considerable difference of opinion remains as to the relation of other factors to the bacillus. Some observers are even yet inclined to think that certain cases of consumption may be satisfactorily explained apart from the bacillus. This view is very questionable.

As regards the lung itself, the resultant condition is more or less uniform, varying in degree according to the stage of the disease. The process is one of gradual disintegration, in which two phases may be recognised: (1) Consolidation, when the affected lung feels relatively solid, and the normal vesicular structure can be but imperfectly distinguished; (2) excavation, when the consolidated mass in part breaks down, leaving irregular spaces, varying in size, presenting an uneven, secreting surface. The cavities (vomices) tend to be largest towards the upper part of the lung. Associated with these changes in the lungs, grave disturbance appears in other organs, notably in the stomach and intestines, the liver, and the kidneys.

While accepting the bacillar origin of consumption, it is impossible to overlook the predisposing influence exerted by certain conditions. The list of such factors is a large one. Pre-eminent among them is Heredity (q.v.). Undoubtedly there exists in many families a tendency to weakness—i.e. a less power of resistance—of the respiratory organs. This may be transmitted through several generations. This want of vital balance in the respiratory apparatus is manifested by recurring 'colds,' without apparently sufficient cause. It is not difficult to realise how the bacilli take root, and flourish more readily under such conditions. It is a Diathesis (q.v.) or disposition which is inherited,

rather than the disease. Greater difficulty is experienced when the question of actual transmission of the disease is considered. Though certain facts, indeed, point to the conclusion, it cannot be said that a congenital infection of child by mother has yet been demonstrated in man. The so-called scrofulous diathesis, in which there is a tendency to a low form of glandular inflammation and degeneration, has been cited in favour of this view. The inter-dependence of scrofula and consumption cannot be denied. Sex seems to have little bearing in reference to consumption. Similarly of little value is the popular belief that the disease is more frequent in the offspring of consanguineous marriages. It is, however, to be borne in mind that such unions necessarily double the chance of a particular family taint being reproduced. Age is a factor of greater moment. It may be said that consumption makes its appearance most frequently between the ages of fifteen and thirty. It frequently attacks persons beyond thirty, but in very young children it is not common. A most important part in the causation of consumption is undoubtedly played by improper sanitary conditions. This is evidenced by the much greater prevalence of consumption in towns and other crowded centres. The statistics of mortality in England illustrate this. In the counties whose industry is chiefly agricultural, the death-rate from consumption is comparatively low, while in Lancashire and other more largely manufacturing counties the rate is high. Badly built, overcrowded dwellings and workshops, with insufficient ventilation and damp, afford the most suitable conditions for the development of consumption. All physicians are agreed that 'perhaps no cause exerts such a decided influence on the production of consumption as the privation of fresh air and exercise.' No better illustration of this can be cited than the excessive mortality from consumption which was at one time recorded in British and foreign prisons. Thus at Millbank Penitentiary, during the seventeen years from 1825 to 1842, the annual mortality from consumption was reckoned at 13 per 1000. The vicious influence of these factors is, of course, increased enormously when, in addition, poverty and want are present. It must be admitted, too, that sedentary occupations generally predispose to consumption. Thus tailors, seamstresses, and similar workers are especially prone to the disease. More especially is this true of occupations whose performance necessitates the inhalation of dust particles—e.g. stone-masonry, knife-grinding, metal-polishing, wood-carving, &c. The dust particles act as irritants of the fine structures which line the air passages and vesicles, inducing chronic changes, which, in turn, are liable to lead to consumption.

The bacillar doctrine has given fresh impetus and scope to the important inquiry as to the contagiousness of consumption. On this subject the evidence is conflicting. The large experience of consumption hospital physicians, such as that of the Drs Williams at Brompton Hospital, points decidedly towards the negative view. On the other hand, the statements of most careful observers, who have again and again recorded cases of infection, are strong in the opposite direction. An unprejudiced review of the facts seems to justify the conclusion that, although consumption is a communicable disease, it is so within certain limits—i.e. the contact and intercourse which, apart from other causes, expose to risk, must be of an extremely close nature. Probably the expectoration of phthisical patients affords the best means of transmission.

There remains the interesting question, whence do the bacilli make their appearance? This is a difficult problem. The fact that the organs of

respiration are more especially affected, seems to point to the conclusion that the bacilli are present in the air. But their presence there is not easily proved. On the other hand, the expectoration of consumptive patients is found to be loaded with the organism. It has further been demonstrated that the bacillus occurs abundantly in the milk of cows suffering from tubercular disease of the udder; and meat obtained from the carcasses of tubercular animals, particularly the liver, kidneys, and glands, cannot be regarded without suspicion. The prevalence of abdominal consumption in young children has been attributed to the ingestion of the bacilli by means of milk. It has further been shown that tubercular disease may be induced through an open wound, to which the bacilli have obtained access.

The symptoms of consumption cannot be fully discussed in the present article. As seen in advanced cases, they are pretty generally appreciated by the non-professional eye; but at first they are treacherous and frequently remain undetected. The early symptoms vary much. There may be nothing but a gradual loss of strength, it may be of flesh; there may be a slight discharge of blood from the throat or chest; there may be a more or less persistent, tickling cough; there may be breathlessness, with or without pain in the chest; or there may be little save an increased tendency to take cold easily, with but tardy power of throwing it off. Or again, the slow beginnings may be expressed by a gradually progressing pallor, and, in the female, by diminution or cessation of the menstrual discharge. Any of those conditions, especially when they show themselves in the adolescent or young adult, are to be viewed with suspicion, and regarded as a sure indication that medical help is necessary. The more experience physicians have in the treatment of consumption, the stronger becomes the conviction that many lives might be saved, if only an opportunity were afforded of arresting the disease at an early stage. It is peculiarly at this point that the greatest skill and prudence are required from the physician. The appreciation of the signs which indicate the presence of consumption, both at this early stage and later, must be left in his hands, and cannot, of course, be treated of here. The later symptoms of consumption are better defined, and are, unhappily, too well known. They are, more particularly, cough, expectoration of a more or less thick, opaque substance, of varying colour, from whitish-gray to green, sometimes of blood, shortness of breath, pain in the chest, gradually advancing emaciation and loss of weight and strength, profuse sweating, especially in sleep, feverishness, diarrhoea. As the disease advances further, there frequently occur swelling of the feet and sores about the mouth. Accompanying these symptoms, grave changes occur within the lungs. These are appreciated with ease by the trained observer. It should be added that all the above-mentioned symptoms must not be looked for in every case of consumption. The type varies endlessly, and some cases run towards a fatal issue with relatively few signs or symptoms, while anatomically the disease is the same.

The duration of consumption varies greatly. In a certain proportion of cases the destructive process is very rapid, and, if unchecked, may lead to death within a few weeks. To this variety the name Galloping Consumption has been applied. The great majority of cases are extremely chronic, and the disease seems from time to time to become stationary. Consumption may terminate fatally only after many years.

As to the curability of consumption opinion has differed much. For long—and, unfortunately, to a considerable extent at the present day—consumption was regarded as incurable, and treatment

adopted in the direction of palliation. More recently, however, the view of its curability, maintained both by Laennec and Niemeyer, leaders of opposite schools of pathology, has received fresh life through Koch's discovery. During the last few years many cases of recovery have been recorded. If those who have reported such have sometimes been affected with that peculiar hopefulness—*spes phthisica*—which is a frequent attribute of the consumptive patient, it must be regarded as a more pleasing indication than the apathy which was formerly too often displayed in respect of such patients, as evidently appointed to die. There is, moreover, reason to hope that we are on the eve of greater possibilities. Never was attention so keenly directed to this once neglected problem. In illustration of this may be cited the institution at Paris in 1888 of an International Congress, which is to meet once in two years for the consideration and elucidation of all questions relating to consumption, with a view to its prevention and treatment. Meanwhile, it may be affirmed that consumption, if suitably treated in the early stage, is curable; that occasionally more advanced cases are cured, and that for all cases much may be done in the way of prolonging life and relieving suffering. The popular mind must be disabused of the idea of the hopelessness of consumption.

The treatment of consumption is one of the most complicated problems which the physician has to face. In its wide sense, it involves a consideration of some of the largest questions relating to social and individual hygiene. From the prophylactic point of view, it includes the study of all points bearing on the causation of consumption. Only thus can the attempt be made to cope effectively with the evil on the large scale. A knowledge of the dependence of consumption on overcrowding, vitiated air, improper ventilation, and other insanitary conditions, ought to lead the responsible authorities to adopt and enforce such regulations as will remedy the evil. Within recent years much has doubtless been effected in this direction. The legislature has taken in hand several departments of this work; and employers, in many instances, have shown a proper interest in the welfare of their employees. But more remains to be done. There is need of increased popular instruction, so that working-people and others may themselves appreciate the dangers which they run by neglect of simple precautions. Further, having regard to the communicability of consumption from the lower animals to man, means should be devised whereby the milk from tubercular cows may be excluded from the market, and the flesh of tubercular animals condemned. These provisions have been embodied in the recommendations of the Paris congress (1888), that tuberculosis in animals should be included in the list of contagious diseases, the animals seized and destroyed, and dairies and milk-houses be subjected to strict scrutiny by competent officers. The danger of phthisical expectoration as a means of transmission has been already alluded to. It is therefore advisable that this, whenever possible, be destroyed by burning, or rendered innocuous by scalding or other satisfactory method.

In respect of the treatment of individuals, much may be expected from prevention. Though lacunæ exist in our knowledge of the life-history of the tubercle bacillus—more especially as regards its access to, and development in, the human body—there is good ground for believing that general depreciation of the system is a favouring factor of much importance. Hence all measures are to be adopted which will place the body under as good conditions as possible, more especially when there is suspicion of a family tendency towards consump-

tion. Open-air exercise, varied according to circumstances, light gymnastics, friction of the skin, and bathing, unless contra-indicated, are to be commended. Sufficient sleep, abundant and regular meals of simple nourishing food, and warm light clothing are essential. Exposure to chills or damp must be strictly avoided, and the utmost care taken that no 'cold' be allowed to persist. If a cough continue, or any other symptom of consumption show itself, medical advice should be obtained at once.

When consumption is distinctly present, there are two lines open to the physician—the *defensive* and the *offensive*—and rational treatment should combine these. In carrying out the *former*, an attempt must be made to improve the general condition, so that effective resistance may be offered to the invasion of the bacillus. For this purpose all means of fattening the body should be adopted; and of these, *par excellence*, cod-liver oil, which has come to be regarded almost as a specific for consumption. As Dr C. J. B. Williams says: 'The beneficial operation of cod-liver oil extends to every function and structure of the body.' Fatty foods, butter, cheese, cream, milk, koumiss, glycerine, &c. are similarly of service. Care must be taken to maintain the appetite. The moderate use of alcohol, in one form or another, is advisable. Attention should be bestowed on the carrying out of those general hygienic rules which have been indicated. The chest should be gently expanded by such means as reading, singing, and regulated open-air exercise. Disadvantageous climatic and atmospheric conditions are to be removed, where possible. This is specially of importance in a moisture-laden climate. Often a change of residence from seaside or city to the highlands proves beneficial, or, where the disease is pronounced, removal from the northern to a more temperate zone. Where comparatively short journeys can alone be contemplated, Bournemouth, Hastings, Ventnor, Torquay, Penzance, and other places on the southern shores of England may be thought of. Where longer ones are possible, the variety is immense, from the Mediterranean and Atlantic stations to the slopes of the Rocky Mountains. In many cases a sea voyage is best; but this is contra-indicated under certain conditions, and should never be undertaken without medical advice. In connection with all these plans, wise consideration will be given to the fact that apparent advantages are unfortunately counterbalanced by disadvantages which are less easily gauged. While much benefit is to be expected in suitable cases, it is unnecessarily cruel to send a patient to die away from home. The *offensive* method of treatment rests on the hypothesis of the opposition offered by certain drugs to the life and development of the bacillus. The first vague feeling after such a system found expression in the various respirators, whose efficacy has from time to time been vaunted. There are, however, grave objections to the use of these. Firstly, such instruments of necessity render the movements of respiration less easy; and secondly, it is questionable whether, in the diseased state of the lungs, much of the antiseptic influence reaches the diseased portion. More recently an attempt has been made to introduce into the body certain drugs, which experiment indicated as antagonistic to the life of the bacillus. These have been administered by the mouth, by the rectum, subcutaneously, and by injection into the air passages directly. Thus creosote, iodoform, terebene, sulphurous acid, menthol, and other drugs, have been exhibited. The method is still on trial. Most encouraging reports have been published from time to time, but it cannot be said that

certainty of result has yet been attained. For the relief of suffering and the palliation of distressing symptoms, an endless number of remedies might be named. No disease taxes more fully the patience and resource of the physician, and, apart from the general lines indicated, each case must be regarded individually.

Consumption in the Lower Animals.—The consumption of the lower animals has been proved to be essentially the same disease as that occurring in man. Its immediate dependence on the tubercle bacillus has been established. It affects the bovine species more especially. It is comparatively rare in the sheep, and very rare in the horse and dog. Pigs, rabbits, and poultry are extremely susceptible to the disease. The same class of causes appears to give rise to it. Its extreme frequency in cows is probably referable to the more or less confined life which these animals lead in comparison with the horse and dog. The udders of the tubercular cows frequently exhibit signs of the disease, and in those cases the *Bacillus tuberculosis* has been demonstrated in the milk. It is a question whether the bacillus is found in the milk of tuberculous animals apart from such local disease. But the probable communicability of the disease from the lower animals to man makes it desirable that consumption should be included among the contagious diseases, so that tubercular cattle may be destroyed. The symptoms presented by tubercular animals are in the main similar to those seen in man, and in the later stages are recognised without much difficulty. At first, however, consumption is less easily distinguishable—a fact which renders legislation on the subject extremely difficult.

Contagion, the communication of a disease from the sick to the healthy, either by direct contact of a part affected with the disease, or through the medium of the excretions and exhalations of the body. The term is sometimes used of all methods by which disease is communicated, but more generally of those in which direct contact has taken place between the healthy body and the diseased one, or some object which has touched it; more subtle means of transference, especially through the air, being termed 'infection.' This distinction, though it cannot be considered a fundamental one, is practically convenient; for some diseases (e.g. syphilis, ringworm) are always, or all but always, propagated by contact; others (e.g. measles, influenza) much more often through the air; while in some (e.g. anthrax) the symptoms and course of the disease are much modified by the method of communication. See INFECTION, GERM THEORY OF DISEASE.

Contagious Diseases Acts were passed in 1865, 1867, and 1868 for the seaport and military towns, Aldershot, Canterbury, Chatham, Colchester, Dover, Gravesend, Maidstone, Plymouth and Devonport, Portsmouth, Sheerness, Shorncliffe, Southampton, Winchester, Windsor, and Woolwich; and in Ireland, the Curragh, Cork, and Queenstown. To a certain extent they also applied in other towns, and similar acts were largely adopted in the British colonies. The main features of this legislation were (1) the registration and police supervision of prostitutes; (2) the periodical examination of these women, which might be compelled; (3) their detention in hospital when necessary. The acts were from the first strongly opposed as contrary to constitutional freedom and public morality, as giving undesirable safety to vicious practices, as dangerous to virtuous women, as treating unequally the two sexes, and as encouraging clandestine prostitution. Their operation was inquired into by a Royal Commission

in 1870, which was generally favourable to their retention; and by a Select Committee in 1882, which reported that the acts had diminished venereal disease, and had increased the efficiency of the army. The army returns, however, leave this fact in some doubt; and while medical and sanitary principles support the acts, and the opinion of the clergy and the police in the garrison towns credited them with good results, they were condemned by a wave of strong public feeling in 1883, and have since been repealed. This repeal, however, has not yet been adopted in the colonies.

Contagious Diseases (Animals) Acts.

This legislation was begun in 1869, but now stands on acts passed in 1878, 1884, and 1886. These acts, and the orders issued under them by the Privy-council, constitute a most important code of administrative regulations for the protection of cattle, sheep, goats, and all other ruminating animals, and also swine, against cattle-plague (or rinderpest), contagious pleuro-pneumonia, foot and mouth disease, sheep-pox, sheep-scab, glanders, farcy, swine fever, and anthrax. The Privy-council have also issued an order relating to rabies in dogs. Since 1888 the acts are administered by the county councils in counties, town councils in boroughs over 10,000, and by the police authorities in smaller towns in England; and in Scotland by certain mixed boards for the counties, and by the town councils in parliamentary burghs. The method of working is that on the report of a local veterinary inspector, the Privy-council declare a place to be infected, and direct all animals suffering from cattle-plague to be slaughtered, compensation being given to the owners out of money provided by parliament. As regards pleuro-pneumonia, the local authority may take the initiative in declaring a place infected, and they provide the compensation for slaughtered cattle out of a local assessment. The same process is followed as regards foot and mouth disease, but the power of slaughter does not exist in this case. The place 'declared' is often only a field or a cow-shed, but may be indefinitely extended. The Privy-council have a general power of making orders with reference to the transit or movement of animals affected with pleuro-pneumonia or foot and mouth disease; and a large part of the administration consists in carrying out these 'movement orders,' which are numerous and modified from time to time. It is the duty of every person having a diseased animal to give immediate notice to the police. For the purposes of these acts the Privy-council has a large jurisdiction over markets, exhibitions, landing wharves, the treatment of cattle by railway companies and on board ship, &c. They are responsible for the regulations connected with the landing of foreign animals, which is allowed only at prescribed places. In connection with this the local authorities have power to provide wharves, lairs, sheds, &c., for the landing, reception, and slaughter of foreign animals.

The Act of 1886 transferred to the Local Government Boards of England and Ireland and the Board of Supervision in Scotland the power of issuing orders relating to dairies, cow-sheds, and milk-shops, and to local sanitary authorities the power of making regulations under such orders. These regulations may deal with the lighting, ventilation, cleansing, drainage, and water-supply of dairies and cow-sheds in the occupation of persons following the trade of cow-keepers or dairymen; the cleanliness of milk-stores, milk-shops, and of milk-vessels used for containing milk for sale by such persons; and may prescribe precautions to be taken by purveyors of milk and persons selling milk by retail against infection or contamination. The result of this transfer

of powers has been to place milk-selling under stricter supervision than hitherto, as it is unlawful for any person to carry on the trade without being duly registered.

Contango. See STOCK EXCHANGE.

Contarini, the name of a noble family in Venice, one of the twelve that elected the first Doge. Between 1043 and 1674, eight Doges were furnished by this family, which also counted amongst its members four patriarchs, and a large number of generals, statesmen, artists, poets, and scholars (see VENICE).—CARDINAL GASPARO CONTARINI (1483–1542) distinguished himself as Venetian ambassador at the court of Charles V., and was papal legate at the Diet of Ratisbon (1541), where he displayed great moderation, seeking by concessions to bring about the reunion of the Protestants with the church.—SIMONE (1563–1633) was Venetian ambassador at several Italian courts, in Spain, in Constantinople, &c., and was a Latin poet.—LUDOVICO (1629–1653) was ambassador in Paris.

Contemporaneity, in Geology, has a somewhat more extended signification than the word bears in ordinary language. When a geologist speaks of the Silurian systems of America and Europe having been accumulated contemporaneously, he does not infer that they were precisely synchronous, but merely implies that each occupies the same relative position in the succession of systems. Each was preceded by a Cambrian and succeeded by a Devonian system; but for aught he can tell, the Silurian period may have commenced earlier or endured longer in one area than the other. Professor Huxley has suggested the term *homotaxis* ('similarity of order') as a substitute for contemporaneity. According to this view we should apply the term *homotaxial* instead of *contemporaneous* to widely separated systems which contain the same assemblages of fossils—all that the proposed term indicates being this, that the order of organic succession was the same in both regions. All the evidence, however, goes to show that in the earlier ages of the world the climate of the earth was not differentiated into zones as it is now, so that faunas and floras were enabled to extend themselves readily in every direction. Hence, although it is impossible to say that any particular bed of palaeozoic or mesozoic limestone in Europe is of precisely the same age as a similar limestone in America, yet it seems in the highest degree probable that the great system to which both these limestones happen to belong was accumulated during one and the same long-continued period. Geologists seem to be justified, therefore, in describing the successive systems of the Old and New Worlds as actually contemporaneous.

Contempt of Court, a disregard of the rules or an offence against the dignity of a court which has power to punish for such offence. Contempts, according to the law of England, may be classed as (1) disobedience to the Queen's writ; (2) contempts in the face of the court, as when a witness refuses to be sworn or prevaricates in his evidence, or where jurymen refuse to give a verdict; (3) contemptuous words or writings concerning a court; (4) refusing to comply with the rules and awards of a court; (5) abuse of the process of a court; and (6) forgery of writs, or any deceit tending to impose on a court. Any act which insults or resists the power of a court or the persons of the presiding judges, or which plainly tends to create a disregard of judicial authority, may be a contempt, as unseemly behaviour, applauding, talking boisterously and obstreperously while the business of a court is proceeding, intimidating a suitor to discontinue his action, kidnapping or corrupting witnesses or

jurors, obstructing officers of court and the like. Contempt is occasionally punished by fine (e.g. of £500 during the Parnell Commission), but oftener by commitment to prison for an indefinite period. Similar powers are exercised by judges in Scotland, where contempts may be punished arbitrarily by censure, fine, or imprisonment, either by the court of its own instance or under a summary complaint by the public prosecutor. In the United States also, the courts have power to fine and imprison all such contempt of their authority, every court being the exclusive judge of its own contempt, and having power to preserve its own dignity. Motions and affidavits for attachments in civil suits are on the civil side of the court, but as soon as the attachment issues, the proceedings are on the criminal side. For Contempt of Parliament, see PARLIAMENT.

Conti, HOUSE OF, a younger branch of the Bourbon House of Condé (q.v.). Its founder and first prince was Armand de Bourbon Conti, brother of the great Condé. He was born at Paris in 1629, and took his title from the little town of Conti, near Amiens. Though feeble and deformed, and set aside for the church, he took with ardour to the career of arms, but after 1657 retired from the world, and died at Pézenas in 1666.—LOUIS ARMAND, eldest son of the preceding, was born in 1661. After a short but promising career in arms, he died childless in 1685.—FRANÇOIS LOUIS, Prince de la Roche-sur-Yon et de Conti, brother of the preceding, and the most remarkable of the family, was born at Paris in 1664. Educated under the eyes of the great Condé, he early conceived a passion for war, and already in his first campaign in Hungary covered himself with glory. Falling into disgrace with the court, he was banished to Chantilly, but pardoned by the intercession of the great Condé before his death. Subsequently Conti served under the Duc de Luxembourg, who was warmly attached to him, and took a brilliant part in the victories of Steinkirk and Neerwinden. In 1697 he narrowly escaped being made king of Poland. On his return to France he was still coldly received by Louis, who, however, was at last forced by disaster to employ him. He received the command of the army of Flanders in 1709, but died on the 22d February of the same year. Saint-Simon, in his *Mémoires*, thus speaks of him: 'He was the delight of armies, the divinity of the people, the hero of officers, the darling of parliament, and the admiration of the most learned savants.'—The last member of the House of Conti was LOUIS FRANÇOIS JOSEPH, who was born 1734, and died at Barcelona, 1807.

Contiguity, LAW OF. See ASSOCIATION OF IDEAS.

Continent. This name, originally applied to a great division of the earth's surface containing a

number of countries, has latterly come to have a more precise scientific meaning. Six continents are recognised by geographers—Asia and Europe (which, strictly speaking, form but one continent, the division between the two being arbitrary and uncertain); the three great triangular peninsulas, Africa, North America, South America; and the vast islands Australia and Antarctica. Antarctica has never been explored, but the evidence of the gradual shoaling of the sea on all sides within the Antarctic circle, and the nature of the rocks dredged in the far south, make the existence of a continent and not an archipelago of oceanic islands round the south pole practically certain.

The earth's surface is divided by the 1000 fathom (6000 feet) line of ocean soundings into two equal parts, one a region of depression surrounding the south pole and stretching northward in three wide branches or ocean-basins, the other a region of elevation surrounding the north pole and stretching southward in three great arms crowned by the continents. All the land rising above sea-level forms collectively the *continental area*, and amounts to $\frac{1}{4}$ of the earth's surface. Geological evidence shows the extreme probability that the continental and abyssal areas have never changed places, but are permanent features of the earth's surface. Continental rocks, granite, gneiss, schist, and their derivatives, differ entirely from those of oceanic islands. Detached portions of the continents, though now far from the mainland, may therefore be readily recognised (see ISLANDS). Around all continents the action of waves has carved out a ledge or terrace, the continental shelf, of variable width, on which the bottom slopes gently from the land to soundings of 100 fathoms, and then abruptly plunges to the oceanic depression (see SEA). The absolute elevation of continents or mountains above mean sea-level cannot easily be determined, on account of the permanent distortion of the sea surface by the attraction of the projecting mass of land. This heaping up of the sea has been calculated at 300 feet for the vicinity of the Himalayas at the Bay of Bengal, and 2000 feet for the Chilean Andes. Dr John Murray calculates the average height of continental land above sea-level as 2200 feet, and gives as probable estimates the mean heights represented in the diagram. Particulars of each of these continents will be found under their respective names.

The continents occur in north and south pairs, united by a narrow isthmus or archipelago, or separated only by a shallow strait. They are directed south-south-eastward, tapering from the north in all cases, and frequently ending in a series of south-pointing peninsulas, which are often partially submerged so as to form archipelagos of small islands on the eastern side. Each continent has an axis or backbone of high land, usually a plateau containing an area of internal drainage, and serving as a

Relative Areas and Average Heights of the Continents.

watershed for rivers flowing to all sides. This high land is situated towards the south, and runs east and west on the whole in Eurasia, giving the

north-flowing rivers long slopes, and the south-flowing streams a short and rapid run. Africa is a transition type, the watershed being on the whole

nearer the east; Australia, more extreme, has the main watershed lying close to the east coast. In the two Americas there is a high western mountain-ridge or plateau running from north-west to south-east, and a low range on the eastern coast, leaving great central, low plains watered by large rivers. The interior of a continent has usually a very low rainfall (see DESERT), and is subject to great extremes of temperature between summer and winter, and between day and night, hence the term continental climate. Land and sea breezes and the Monsoons (q.v.) of tropical coasts result from this circumstance.

Continental System, the name given to Napoleon's plan for shutting England out from all connection with the continent of Europe. This system began with Napoleon's famous 'Berlin Decree' of November 21, 1806, which declared the British Islands in a state of blockade, and prohibited all commerce and correspondence with them; all merchandise belonging to an Englishman became a lawful prize, and all trade in English goods entirely prohibited. No ship coming direct from Britain or from a British colony was allowed to enter any port.

Britain was not long in making reprisals. By an 'Order in Council', issued January 7, 1807, all neutral vessels were prohibited from entering any port belonging to France or her allies, or under her control. Every neutral vessel violating this order was to be confiscated with its cargo. Still more oppressive for neutral commerce was a second order in council of November 11, 1807, by which all harbours and places of France and her allies in Europe and the colonies, as well as of every country with which England was at war, and from which the English flag was excluded, were placed under the same restrictions as if strictly blockaded. These orders were followed by new French measures. By the Milan Decree of December 17, 1807, strengthened by a second of January 11, 1808, from the Tuileries, any vessel, of whatever nation, that had been searched by an English ship, had submitted to be sent on a voyage to England, or paid any duty to the English government, was to be declared *denationalised*, and treated as English.

Most of the countries of Europe were coerced by Napoleon into joining the continental system. The great war of 1812 against Russia was largely owing to her refusal to adhere to it any longer. It was a violent interruption of human intercourse, which could not last long, and could only serve to strengthen the hatred of Europe against French tyranny. Accordingly, with the breaking up of Napoleon's power, the continental system fell to the ground. The policy of England in connection with the continental system can be justified only on the ground that it was necessary to avert a supreme national danger. It was not without its mischievous results, for the measures adopted in regard to neutral commerce led to the American war of 1812.

Contorted Strata are beds which are highly folded, plicated, and twisted—the folds being extremely irregular, and giving rise to rapid changes in the direction and angle of inclination. Contorted strata are frequently crumpled and puckered—the fossils and pebbles which they may chance to contain being compressed, flattened, and distorted—facts which show that the beds have been subjected to great crushing and squeezing.

Contour. When, on a map of any district or country, a line is drawn through points on the earth's surface which are all at the same height above mean sea-level, the curve so obtained is termed a *contour-line*. For equidifferent altitudes a series of such lines may be drawn. It is obvious

that they may be ideally laid down by projecting orthographically on the map the sections of the earth's surface made by a series of horizontal planes at equal distances apart; or (what is the same thing) were the sea-level to rise 100 feet, then to 200 feet, and so on, above its normal level, the sea-margins made at each successive rise would be the contour lines of the district for 100 feet, 200 feet, &c. These lines, which are drawn on British Ordnance Survey maps for intervals of usually 50 feet, however they may vary in form in different cases, have certain common properties which render them of assistance to the surveyor, engineer, and geographer. Suppose, for example, the case of a hemispherical hill be taken (see fig.), and that the contours (which are, in this case, concentric circles) are drawn for each 100 feet of altitude. It will be noticed that where the shortest distance between two successive contours is least, there the hill is steepest; for, in ascending the hill at that part, a given length inwards horizontally is accompanied by the greatest vertical ascent. In other words, the steepness of slope or gradient at any point in any given direction is inversely as the distance between the contours at that point in the given direction. The line of steepest slope at any point is therefore the shortest line which can be drawn to the next contour which it cuts at right angles. This is the course which would be taken by water running down the hillside, and hence is termed a *stream-line*. Thus in any given system of contour-lines the corresponding system of stream-lines can be obtained by drawing a system of orthogonal curves.

The method of contours has found many applications in science besides the one already detailed. Especially in meteorology has it been of service; here isothermals and isolars drawn on a map are simply lines drawn through points having the same temperature and barometric pressure respectively; the corresponding stream-lines being lines of flow of heat or of atmospheric pressure. Similarly, lines of equal magnetic dip, variation, and intensity are examples of applications in terrestrial magnetism.

The method is also applicable to other dimensions in space than those we have dealt with. The contours of a curve are points; of a surface (exemplified above), curves; while those of a solid are surfaces. From the examples given it may be seen that a contour is a point, line, or surface at, along, or on which some physical property or characteristic is constant. Generally the advantage of the method is that by its means the mutual variations of three quantities may be represented by lines in two dimensions.

The method is also applicable to other dimensions in space than those we have dealt with. The contours of a curve are points; of a surface (exemplified above), curves; while those of a solid are surfaces. From the examples given it may be seen that a contour is a point, line, or surface at, along, or on which some physical property or characteristic is constant. Generally the advantage of the method is that by its means the mutual variations of three quantities may be represented by lines in two dimensions.

Contraband of War (Lat. *contra bannum*, 'against the proclamation') is a name applied to certain commodities during hostilities between states which acknowledge what are called the laws of nations. One such law is, that neutral nations must not carry on, for the advantage of either of the belligerent powers, any branches of commerce from which they are excluded in time of peace. Another is, that the name of contraband of war shall be given to such articles as pertain to military or naval warfare—guns, ammunition, and stores of all kinds. Unless there are special treaties, defining exactly what articles are contraband of war, the interpretation of this law often leads to much embarrassment. Another law insisted on by England during the Napoleonic war was, that each belligerent shall have a right to visit and examine neutral ships, to

see whether they carry any articles which are contraband of war, and which seem likely to be intended for the enemy. A neutral state may carry on ordinary trade with either belligerent except when prevented by blockade (see BLOCKADE); but the ships, according to the above rules, must not contain articles contraband of war; nor must a continuous land frontier be crossed by such commodities. If a merchant evades these rules, he does so at his own risk; his merchandise may be seized, and his own government will not protect him. By the law and practice of nations, it is for the Admiralty Court of the capturing power to decide what is or what is not contraband of war. Upon such questions it is the province of this tribunal to adjudicate, and from its final judgment there is no appeal. At various times discussions have arisen whether corn, hay, or coal can ever be included in the list of articles contraband of war; they are obviously articles of peaceful commerce, but they are also essential to the maintenance of an army, and sometimes a supply would give one belligerent a great advantage over the other. Especially is this the case in reference to coal in the present age of war-steamers.—Contraband in commerce depends upon the special laws of each country. See SMUGGLING.

Contra-bass. See DOUBLE BASS.

Contract. The law of contract occupies a prominent place in all modern systems of jurisprudence, and different nations are in closer agreement as to its principles than in regard to any other department of law. A contract may be defined as the voluntary agreement of two or more persons, by which something is to be given or done upon the one side, for a valuable consideration, either present or future, upon the other side. English lawyers usually adject to this definition the qualification that the agreement is enforceable by law, an agreement not enforceable by law being regarded as void. Every contract requires a consideration, a *quid pro quo*, but as a general rule any consideration, adequate or inadequate, will be sufficient. For the making of a contract there must be a communication between the parties of their intention—i.e., in one shape or another, there must be offer and acceptance of distinct terms. An offer or proposal can be revoked at any time before it is accepted; and in strict law, silence does not give consent. When silence is taken to constitute acceptance, it must be silence under such circumstances as to amount to acquiescence. An acceptance must be unqualified, otherwise there is no contract. As the validity of a contract rests upon the consent of parties, persons legally incapable of giving consent cannot be parties to a contract. Contracts made by a person under the age of twenty-one are as a general rule voidable, unless they have been made for his benefit, or, as in England, for his 'necessaries.' And persons in a state of absolute drunkenness cannot contract, although a lesser degree of intoxication may be compatible with legal consent. Similarly, contracts made by a lunatic are voidable when it can be shown that his state was known to the other contracting party. Further, the consent given must be genuine, and a contract will be void if there is mistake or error in either of the parties with regard to any essential particular. Thus, if A sell to B a bar of brass in the belief that it is a bar of gold, and B buy in the same belief, the contract is bad by error. Misrepresentation, or innocent misstatement of fact, and fraud, or wilful misstatement of fact, will also vitiate a contract, as will force or fear or undue influence exercised to compel the consent of either of the parties. A contract may also be void by impossibility—e.g. when the thing

agreed to be done is naturally impossible, as in the case of a pianoforte player who is prevented from performing his agreement by dangerous illness; or impossible by construction of law, as when a change in the law of the country supervenes upon and contradicts a private agreement. Besides these, the law refuses to recognise contracts to perform any illegal act, as to burn a house or steal a horse; and such an agreement may be in itself a crime, as conspiracy. Contracts against good morals, as, e.g., an agreement to pay the price of prostitution, are denied legal recognition and enforcement, as also are agreements against the public policy of the country where they are made. Examples are agreements in fraud of the revenue, as in smuggling transactions; or contracts in restraint of marriage, which are held to be against public policy as tending to decrease the population. Thus a contract not to marry is void.

Contracts are variously classified. The law of Scotland adopts the old division of the civil law into Nominate Contracts and Innominate Contracts. The nominate contracts are loan, commodate, deposit, pledge, sale, permutation, location, society or partnership, and mandate. The law of England distinguishes between Contracts of Record and Contracts under Seal—both of which are formal, or dependent for their validity upon their form—and simple contracts, which depend for their validity upon the presence of consideration. Contracts of record are the judgments of a court; recognisances, as contracts made with the crown in its judicial capacity; and the obsolete acknowledgments of debt known as Statutes Merchant and Staple. Deeds and bonds may be taken as examples of contract under seal. Of simple contracts, some require no specialties of form; others are by law required to be in writing, as, e.g., a bill of exchange or an assignment of copyright. Contracts are distinguished into express or implied accordingly as they are based upon formal statements in words, spoken or written, or upon matter of inference and deduction either from the conduct of the parties or from the provisions of law. They are also distinguishable into executed contracts, where the transaction is completed the moment the agreement is made, as where an article is paid for and delivered over the counter, and executory contracts, where some future act is to be done after the arrangement is completed, as where an agreement is made to build a house in six months. A contract of benevolence is one made for the benefit of only one of the contracting parties, as mandate or deposit. See BREACH, DAMAGES.

The remedy for breach of contract is an action for a certain sum due by the defaulter or for damages, ascertained by a jury; but where the remedy of damages is inadequate or unsuitable, the courts will enforce a contract by decree for specific performance of the thing agreed to be done, or by injunction forbidding an act agreed not to be done.

Contractility. See MUSCLE.

Contractions. See ABBREVIATIONS, PALÆOGRAPHY.

Contract Notes, also called BOUGHT AND SOLD NOTES, or ADVICE NOTES, are notes of a purchase or sale signed by a broker, and delivered to his principals, by which the bargain through him is completed. They are used by all kinds of brokers, and the following is the form of a *stockbroker's* contract and note:

2 OLD BROAD STREET, LONDON, 20th December 1888.
BOUGHT by order and on account of A. B., Esq. (subject to the rules and regulations of the London Stock Exchange),
20 London Street Tramway Shares, at £16.....£320 0 0
Brokerage..... 1 12 0

C. D. & Co.,
Sworn Brokers.

£321 12 0

These notes are, in fact, transcripts from books in which it is the practice of brokers to enter or register their transactions. The bought notes and the sold notes are respectively delivered to the principal parties; and as they contain the essential parts of the bargain, they will suffice as evidence, in the absence of a corresponding entry in the broker's books; but if they describe the particulars differently or incorrectly, as one species of goods for another, or erroneously state the terms, no contract arises, and a variation of this nature cannot be corrected by a reference to the broker's book.

In England, such written notes are required by the Statute of Frauds (29 Charles II. chap. 3) to prove a contract; while in Scotland, except in certain cases, any kind of evidence will be admitted in proof (see **PAROLE EVIDENCE**; see also **BROKER, SALE**).

Contralto is the deepest or lowest species of musical voice in boys, in eunuchs, and best of all in women, where its beauty of tone gives it the preference. This quality of the human voice was too much neglected by the French and German composers and singing-masters. Rossini and the Italians have, on the other hand, abundantly utilised its capabilities, and it is now one of the normal parts in the choral music of all nations. The powers of expression which it possesses are quite peculiar, and cannot be supplied by any other kind of voice. Its tone-character (timbre) is serious, spiritual, tender, and romantic. The low contralto in particular has a fullness of tone combined with power in the lower range. The high contralto has generally the same range of compass as the mezzo-soprano, but differs from it in the position of the cantabile and in its character of tone. Contralto voices generally consist of two registers, the lowest beginning at F or G below middle C, and reaching as high as the A or B above it. The higher notes up to the next F or G partake more of the character of the soprano. See **VOICE**.

Contrat Social ('Social Contract') is the name of a famous work (1762) by J. J. Rousseau, and of the theory maintained in it that government is based on the consent, direct or implied, of the governed. See **ROUSSEAU**.

Contravallation. **LINES OF**, form a chain of works round a besieged place to resist the sorties of the garrison. See **BLOCKADE, CIRCUMVALLATION, and SIEGE**.

Contrayerva, a medicine once in much repute against low fevers, and as a mild stimulant and diaphoretic, also as efficacious against snake-bites, whence the Spanish name, consists of the root-stocks (rhizomes) of different species of *Dorstenia*, a tropical American plant of the natural order Artocarpaceæ. The genus is remarkable for the plane receptacle in which the numerous small flowers are depressed, the female flowers more deeply so.

Control Department. See **COMMISSARIAT**.

Convalescent Hospitals are institutions of the greatest importance. Many patients die on returning to their own unhealthy homes from our ordinary hospitals; the convalescent home or hospital supplies a valuable stage in the process of cure. Either a series of detached cottages or one large and well-appointed house may serve to secure pure air and wholesome treatment. Of the latter kind, one of the first and best models was the magnificent establishment at Vincennes, founded in 1857. It contains more than 400 beds; permits an average stay of from twenty to thirty days; and in three years received 14,000 convalescent artisans.

Convallaria. See **LILY OF THE VALLEY**.

Convection. See **HEAT**.

Convent. See **MONACHISM**.

Conventicle (Lat. *conventiculum*, a diminutive of *conventus*) originally meant a cabal among the monks of a monastery. The word was given as an appellation of reproach to meetings of the English and Scottish Nonconformists in the 17th century. Severe statutes were often passed for the suppression of these conventicles, especially the Conventicle Act of 1664, which was repealed by the Toleration Act of 1689.

Convention, in Diplomacy, is a kind of treaty (especially military) of a temporary kind.

In Politics, it is a branch of the royal prerogative of Britain that no parliament shall be convened by its own authority, or by any other authority than that of the sovereign. Where the crown is in abeyance, this prerogative cannot of course be exercised, and the expedient of Convention Parliaments has been resorted to, the enactments of which shall afterwards be ratified by a parliament summoned in accordance with the provisions of the constitution. The convention parliament which restored Charles II. to the throne met five weeks before his return, and was afterwards declared to be a good parliament, notwithstanding the absence of the king's writs. In like manner, at the Revolution of 1688, the Lords and Commons, on the summons of the Prince of Orange, met in convention, and disposed of the crown and kingdom, and this convention was subsequently declared to be really the two Houses of Parliament, notwithstanding the want of writs and other defects of form. Under the name of Convention there also took place a meeting of the Estates of Scotland, called by the Prince of Orange on the same occasion. The word convention was frequently used in the United States during the struggles with the British authorities which preceded the revolutionary war. For the French National Convention, see **FRANCE**. For the Convention of Royal Burghs, see **BOROUGH**.

Conversa'no, a town of South Italy, 18 miles SE. of Bari. It has a fine cathedral, and a trade in wine, oil, almonds, and cotton. Pop. 11,006.

Conversion, a theological term applied to the conscious change of heart prompting the repentant sinner to a new life, which is part of the process of regeneration. Popularly the name means the sensible experience of this, and obviously there will be as much variety in its intensity and immediateness in individual cases as there was in their temperaments and antecedent spiritual conditions. The man who really knows something of the human heart will no more sneer at the grotesque expression of his experience from the lips of an awakened collier than he will smile at its intensity in the pages of a St Augustine or a Bunyan.—The word is applied also to a change of religion or of creed, as that of John Henry Newman from the Anglican to the Roman Catholic Church. By those who disapprove the change, such a conversion is called *perversion*.

CONVERSION, in Logic, signifies that one proposition is formed from another by interchanging the subject and predicate. Thus, 'Every A is B' has for its converse, by simple conversion, 'Every B is A' (which is not necessarily true). For the rules of conversion, see any handbook of formal logic.

Conveyancing. A conveyance may be defined as the form prescribed by law or custom for transferring property from one person to another. In the earliest stage of society, before written titles and contracts were in use, property was transferred by symbolical acts, performed in the presence of witnesses. Thus, in Ruth, iv. 7, a person surrendering his rights binds himself by plucking off his

shoe and giving it to his neighbour; 'and this was a testimony in Israel.' Among the ancient Goths and Swedes, the conveyance of land was made in the presence of witnesses, who extended the cloak of the buyer, while the seller threw into it a clod of land. Similar to these symbolic forms are the old English and Scottish modes of conveyance by solemn delivery of seisin, sasine, or possession. Goods have always been transferred with less ceremony than land; but the customs of ancient markets provided in certain cases for delivery in presence of witnesses, that frauds and disputes might be avoided.

Written forms of conveyance are almost as old as the art of writing. An early example is given in Jer. xxxii. 9-12, where the prophet describes his purchase of the field of Hanameel, and the book or written evidence of the purchase subscribed by the parties and their witnesses. The Romans carried the art of conveyancing to high perfection. They had public registers in which formal documents might be recorded; and the same legal forms were used by notaries and lawyers throughout the empire. The Roman law favoured freedom of alienation, and applied the same principles to movable and immovable property. When the barbarians broke into the empire, they brought their primitive customs with them; and Sir H. Maine has shown that barbarian custom and Roman law combined to form the feudal system. The great aim of feudalism was fixity of tenure; but the churchmen, who were also the lawyers and conveyancers of the period, were led by their own interest, and also by their superior education, to favour free alienation, both *inter vivos* and by will.

In England and in Scotland feudal ideas so far prevailed, that for some centuries the owner of land was hampered in dealing with it by the incidents of his tenure. He was liable for military or other service, and his land was subject to many incidental claims of a vexatious nature (see COPYHOLD, ESCHEAT, FEUDALISM, FINE, FREEHOLD). The church lawyers were driven to devise a whole system of conveyancing, the object of which was to enable corporations and private persons to evade the strict rules of the common law. Political insecurity led to the invention of other forms of secret conveyance. In England by the end of the 17th century the art of conveyancing had become a complicated mystery, and all dealings with land, in the way of commerce or of family settlement, were attended with expense and difficulty. Modern conveyancing has been rendered more simple and reasonable, and, on the whole, less expensive, by a series of reforms extending from the acts prepared on the advice of the Real Property Commissioners in 1832-33 to the Conveyancing Act, 1881, and the Settled Land Act, 1882.

In Britain it is not necessary to employ a professional person to prepare a conveyance; but the risk run by those who trust to a deed or will drawn by an unskilled person is considerable. Conveyancing is part of the ordinary work of solicitors, and in Scotland of writers to the Signet. In England many members of the bar devote themselves entirely to conveyancing; and there is also a special class of practitioners known as conveyancers who are members of the Inns of Court, but not called to the bar. Like solicitors, conveyancers are required to take out an annual certificate. In some of the large cities in the United States, companies have been formed to undertake conveyancing, and to guarantee titles to real estate. In learning and practising his art, the conveyancer is much assisted by collections of precedents, which contain the styles and forms which have been found most safe and useful. By turning over any of the books of precedents now in use, even the

ordinary reader may obtain some notion of the variety and the importance of modern conveyancers' work. In the United States the laws of conveyancing are not uniform; but in general the essentials of a conveyance of land are that it shall be in writing, signed and sealed by the grantors, acknowledged before the officer appointed by law, and delivered and recorded in the office appointed. In most states conveyancing is done by members of the bar, but elsewhere by a class of skilled conveyancers who are not otherwise professional lawyers.

Convict. See PRISON, CRIMINAL LAW.

Convocations (from Lat. *convocare*, 'to call together') were originally provincial synods of the clergy or the ancient ecclesiastical councils of the archbishop, but became incorporated into the English constitution of church and state, and endowed with certain parliamentary privileges. Some writers distinguish between councils and convocations—the former as being for spiritual purposes, and summoned without authority from the crown; the latter as being for civil purposes, and by command of the crown. This distinction, however, has no foundation in fact, the truth being that the same assemblies discharged ecclesiastical functions, such as the enactment of canons, and civil functions, as the voting of subsidies to the crown, since the clergy were not subject to taxation save that levied by themselves in their provincial synods. The circumstances attending the famous assembly at Northampton in 1282, in the reign of Edward I., helped to settle the form which convocations have since assumed. In England the provinces of Canterbury and York have each their convocation. Previous to the Reformation these were sometimes convened into a National Synod; but since then, matters have usually been concluded in the convocation of Canterbury, and transmitted to York for concurrence.

A convocation consists of three elements—(1) the archbishop; (2) the suffragan bishops of the province; (3) the clergy of the second order. They originally met in one assembly, but since the beginning of the 14th century the clergy in the province of Canterbury have retired into a distinct chamber, presided over by a prolocutor, with officers and journals of their own. These two bodies are called the Upper and Lower Houses. In the Convocation of York the same distinction exists, but on the occasions of their meeting, the business has been generally conducted in one assembly. The archbishop has the sole power of summoning, presiding, and proroguing; he has also a veto upon all measures. He cannot, however, summon without authority from the crown. The Upper House is the proper *locus synodi*, where the bishops have a right to sit and vote, and before the Reformation the mitred abbots had place there also. The Lower House consists of the lesser dignitaries, as deans and archdeacons, and the proctors sent by capitular bodies and by the parochial clergy. In Canterbury the beneficed clergy only elect, and they send one proctor for each diocese; in York all the clergy elect, and send one proctor for each archdeaconry. The Lower House deliberates on matters proposed by the archbishop; it may present petitions to the Upper House and state grievances, be with it in judicature on persons convened, and dissent from and so hinder the passing of any synodical act. Till 1534 the provincial synods or convocations could enact canons at pleasure, but in that year was enacted the statute 25 Henry VIII., chap. 19, making a license from the crown necessary before any new canons could be framed or published.

The passing of subsidies in convocation ceased in 1665, and the records were destroyed in the fire of London in the following year. Meetings of convo-

cation fell into abeyance in 1717, being indefinitely prorogued as a punishment for the synodical condemnation of a book by Bishop Hoadly, who was high in favour with the government. They have been revived (in 1852 for the province of Canterbury, in 1856 for York) with considerable advantage to the church, but their action has been and is greatly restricted. In Ireland the convocations of the four provinces assembled at Dublin, all together, and were on the model of those in England. From the Union downwards, the Irish convocations never assembled. Since the disestablishment the legislative assembly of the Protestant Episcopal Church is called the General Synod. An act of parliament was passed in 1663 for regulating the meetings of convocation in Scotland; but shortly after the Revolution of 1688, the Episcopal Church ceased to be the national establishment; and ever since the meetings of the Presbyterian Church, embracing clergy and laity, have been called General Assemblies. See ASSEMBLY, SYNOD.

The position of the Church of England as respects its convocations is exceedingly anomalous, but is incidental to certain circumstances in the constitution and polity of the country. As practically interwoven with the state, the church possesses little independent action; its articles, liturgy, organisation as to benefices, &c., are all affected by civil statutes; while its discipline falls within the scope of the ecclesiastical courts, a class of tribunals apart from the ministering clergy. The church, therefore, in its capacity as an institution to teach certain doctrines of religion, is left little to do in the way of jurisdiction. It is further urged, as a reason for restricting the power of convocation, that being purely sacerdotal, it might be apt to run into excesses, and put forth claims adverse to the prevailing tone of sentiment on religious matters; that, in short, as things stand, it is safer for the public to be under the authority of parliament than to be subject to the ordinances of a body of ecclesiastics. At the same time it is generally allowed that some kind of reform is desirable, though how this should be effected in a manner satisfactory to all parties it would be

difficult to say. The convocations of Canterbury and York assemble annually at the opening of parliament, each keeping up its own distinctive customs. See Trevor's *Convocations of the Two Provinces*; Cardwell's *Synodalia*, and *Documentary Annals*; Lathbury's *History of the Convocation of the Church of England*.

Convolvulus (Lat. *convolvere*, 'to twine together'), a

genus of plants, the type of the order Convolvaceæ. This order contains about 800 known species, herbaceous and shrubby; generally with a twining stem and milky juice, chiefly tropical. Many are cultivated as ornamental plants, particularly species of *Convolvulus* and *Ipomœa*.

Convolvulus (Calystegia sepium).

The acrid milky juice is often strongly purgative; and jalap and scammony are products of this order. Some species, however, have large farinaceous roots, capable of being used as food, of which the Batatas or Sweet Potato (q.v.) is the most important. A few are natives of Britain, and are known by the name of Bindweed. A common name in the United States is Morning Glory. *C. arvensis* is a troublesome weed in some sandy soils in England, and *Calystegia sepium* in richer soils. The wood of *C. scoparius*, a shrubby species, native of the Canary Isles, called 'Rosewood,' or *Lignum Rhodii* by apothecaries, has so strong a smell of roses that the essential oil it yields on distillation is employed to adulterate the attar of roses.

Convoy (Fr. *convoi*) is the name given to one or more ships of war appointed to protect a fleet of merchant-vessels against the attacks of an enemy or of pirates. If a merchant-ship parts company with the convoy, or neglects to obey the convoy's instructions or signals, all claims of insurance are forfeited. The name is sometimes applied to the merchant-vessels so escorted. In the military service a convoy is a train of wagons or canal boats laden with provisions, treasure, or warlike stores, and escorted by a detachment of troops.

Convulsion, in Medicine, is sometimes used of any involuntary contraction of the voluntary muscles of the body; but especially of seizures in which the body is thrown into violent spasmodic contractions, the sensibility and voluntary motion being for a time suspended. In adults convulsions almost always indicate the presence of grave disease, either of the brain (particularly Epilepsy, q.v.) or of the kidneys. In children, especially before the age of three years, they are of much more common occurrence, and, though serious in themselves, may be due to temporary and comparatively trifling causes. The following description applies chiefly to the convulsions of children. A fit of convulsions may last from a few minutes to some hours, and may readily prove fatal, if not relieved within a short period. The first symptom observed is often a twitching of particular muscles or groups of muscles, and a change in the habitual expression or colour of the face, with distension of the features, and turning of the globes of the eyes suddenly upwards. The fingers are sometimes clenched in the palm, and the feet turned inwards; sometimes, however, convulsions occur absolutely without warnings of this kind, and even in the midst of perfect apparent health. Their cause is usually to be found in some source of irritation, especially in the digestive organs; as, for instance, disordered dentition, worms in the intestine, indigestible or unsuitable food, &c. Most epidemic fevers are also apt to be attended, in children, by convulsions in their early stages, and if severe, particularly in the case of whooping-cough, during their progress as well; and diseases of the brain and its membranes at every stage. Convulsions are greatly promoted by bad ventilation and injudicious feeding, with deficient exercise; and a great part of the cure consists in discovering and removing the causes of the disease.

When a child is suddenly seized with a tendency to spasm, such as twitching of the features, or contractions of the fingers and toes, it should be placed at once in a very free current of air, with its feet towards the fire; the extremities should be kept warm, and a cold lotion may be applied to the head, especially if there is much flushing of the face; a little castor-oil may be given unless the bowels are loose; and if there is flatulence, the belly may be rubbed with a warm hand, or with some simple stimulating liniment, such as camphorated oil. If an actual convulsion occur, the feet, or if

possible the whole body, should at once be put in hot water to which a little mustard has been added, and cloths wrung out of cold water frequently applied to the head. If there is any suspicion that worms or undigested food may be the cause, a purgative Clyster (q.v.) should be given; and aperient medicine by the mouth as well, if the child be able to swallow. Nothing more should be attempted without medical advice. The further treatment generally consists in the administration of nerve sedatives, especially bromide of sodium or potassium and chloral, and in obstinate cases chloroform, with careful attention of course to any cause of irritation that may be present.

Convulsions are rare amongst horses and cattle. In young dogs, however, they frequently occur from intestinal worms, disordered digestion, or in connection with distemper or other debilitating diseases; they usually disappear when their special causes are removed.

Convulsionaries, the name given to a fanatical sect of Jansenists who sprang up in France about 1730. Their meeting-place was the churchyard of St Médard, in a suburb of Paris, where was the tomb of a certain Francis of Paris, who died in 1727, and was reckoned very holy by the Jansenists on account of his extravagant asceticism. At this tomb a multitude of people poured forth fanatical prayers, preachments, and prophesying. Miracles are also alleged to have been performed, for proof of which we are referred to a work written by M. Montgeron, a French senator, and entitled *La Vérité des Miracles opérés par l'Intercession de François de Paris* (Paris, 1737). After 1731 the fanaticism of the convulsionaries increased to utter madness. 'They threw themselves into the most violent contortions of body, rolled about on the ground, imitated birds, beasts, and fishes, and at last, when they had completely spent themselves, went off in a swoon.' In 1733 the king issued an order for the imprisonment of these fanatics, but it was found impossible to put a complete stop to the mischief. They took to predicting the downfall of the throne and the church, which prophecy the French Revolution appeared to fulfil. They were not much heard of in Paris after the middle of the 18th century, but have occurred in country-places at various times within the present century. They brought Jansenism into so much disrepute, that Voltaire declared the tomb of Francis to be the grave of Jansenism. See Mathien, *Histoire des Miracles et des Convulsionnaires* (1864).

Conway, a river in North Wales, famous for the bold romantic scenery along its higher, as well as for the richly beautiful scenery along its lower course. It rises in a small mountain-lake round which meet the three counties of Merioneth, Denbigh, and Carnarvon; and it runs 30 miles northward past Llanrwst and Conway to Beaumaris Bay. In its last ten miles, a smoothly-flowing if winding stream, it is navigable for vessels of 100 tons. At Conway it is half a mile broad at spring-tides, which rise here from 21 to 24 feet. Pearl-mussels are found at its mouth.

Conway, or ABERCONWAY, an ancient and picturesque little seaport town of North Wales, in Carnarvonshire, situated on the left bank of the river Conway at its estuary, 4½ miles NW. of Chester by rail. The river is crossed by a fine tubular bridge constructed by Stephenson in 1848, as well as by a suspension bridge built by Telford in 1826 (see BRIDGE). The town is triangular in form, and is surrounded by a high wall 12 feet thick and 1 mile in circumference, pierced by four Moorish-looking gates, and crowned by twenty-one round towers. In its south-eastern corner are the magni-

ficent remains of Conway Castle, rising proudly from a rock above the river. It was first built by Hugh Lupus, Earl of Chester, and rebuilt in 1284 by Edward I., to check the Welsh. Its walls are 12 to 15 feet thick, with eight vast towers, four of which are each surmounted by a slender turret. The Plas Mawr ('great mansion') is a noble timber house erected in 1585, its exterior and interior profusely covered with ornament. A Cistercian abbey was founded here by Llywelyn ab Iorwerth, prince of North Wales, in which Llywelyn the Great was buried. The Castle Hotel now occupies its site. Pop. (1881) 3179. Conway (a chartered borough since 1876) is one of the six Carnarvon boroughs. It is still visited by vast numbers of tourists, but as a place of resort it has been left far behind by Llandudno, 4 miles to the north.

Conway, HUGH, the pseudonym of Frederick John Fergus, who was born in 1847, the son of a Bristol auctioneer. He adopted that pseudonym from the school frigate *Conway*, stationed on the Mersey, which he entered when he was thirteen for the purpose of training for a seafaring life. His father set his face against this, so young Fergus entered the auctioneer business, employing his leisure in writing clever newspaper verse and occasional tales. Some songs of his were accepted and published in 1878, a volume of verse in 1879; but it was the issue and rapid sale of his melodramatic story, *Called Back*, as vol. i. of Arrow-smith's Bristol Library (1884), which made him famous. Up till April 1888, 348,000 copies of this book had been sold. Fergus sold his share in the auctioneer's business in Bristol, and went to London, where he adopted the profession of authorship. His *Dark Days* followed, and just as in *A Family Affair*, and other works which he now produced in rapid succession, he had begun to show higher capabilities as a novelist, he died of malarial fever at Monte Carlo, 15th May 1885.

Conway, MONCURE DANIEL, American author, born in Virginia in 1832, entered the Methodist ministry in 1850, but, after a course at the Cambridge divinity school, settled as a Unitarian preacher in Washington in 1854, and in Cincinnati in 1857. He was a strong opponent of slavery, and in 1863 came to England to lecture on the war. In London he obtained a charge, and remained there till 1884, when he returned to the United States. He contributed largely to the daily press and to magazines, and has published, among other works, *The Rejected Stone* (1861), *The Golden Hour* (1862), *Republican Superstitions* (1872), *Idols and Ideals* (1877), *Demonology and Devil-lore* (1879), *Thomas Carlyle* (1881) and *Pine and Palm* (1887).

Cony, or CONEY, an old English name for the rabbit (*Lepus cuniculus*). In the authorised version of the Bible, as also in the revised version, the word occurs as a translation of the Hebrew *Shaphan*, which in all probability refers to the common *Hyrax syriacus*, also called Daman. See HYRAX.

Conybeare, WILLIAM JOHN, joint-author with Dean Howson of a widely known *Life and Epistles of St Paul* (1851), was born 1st August 1815, son of William Daniel Conybeare (1787-1857), the eminent geologist, who in 1844 became dean of Llandaff. He was educated at Westminster and Trinity College, Cambridge, of which he became a fellow. In 1842 he was appointed principal of the newly-founded Liverpool Collegiate Institution, which ill-health compelled him to exchange for the vicarage of Axminster. He died at Weybridge in 1857. *Essays, Ecclesiastical and Social* (1856), and a novel, were his only other works.

Cony'za, an unimportant genus of Compositæ (sub-order Corymbifere). *C. squarrosa* is known

as Fleabane and Ploughman's Spikenard, and has a strong peculiar smell, traditionally said to drive away fleas and gnats.

Cooch Behar. See BEHAR.

Cook, DUTTON, dramatic critic and author, the son of a solicitor, was born in London, 30th January 1829, spent four years in his father's office, then entered a railway office, which he left to follow the full bent of his literary and artistic tastes. He studied painting and engraving, wrote a successful melodrama, acted as dramatic critic for the *Pall Mall Gazette*, 1867-75, and then for the *World* till his death, 11th September 1883. He wrote for various newspapers and magazines, including *Temple Bar* and *Chambers's Journal*, and his eight novels, and others, were always interesting and well written, but sometimes failed in catching the average novel-reader. He wrote the dramatic and theatrical lives for the first two volumes of the *Dictionary of National Biography*, was also author of *A Book of the Play* (1876), *Hours with the Players* (1881), and *On the Stage* (1883).

Cook, ELIZA, a favourite minor English poetess, daughter of a London tradesman, was born at Southwark in 1818. She contributed poetical pieces to various magazines from an early age, and issued her *Melanie and Other Poems* in 1838, which, along with the issue of volumes in 1864 and 1865, established her reputation as a meritorious verse writer of sound morality, and clear, sensible, and simple treatment. She conducted *Eliza Cook's Journal* (1849-54) till ill-health obliged her to relinquish it; in 1864 a pension of £100 a year was conferred upon her by government. She has also written *Jottings from My Journal* (1860), and *Laconics* (1865).

Cook, JAMES, one of England's greatest navigators and maritime explorers, was born at Marton, in Cleveland, Yorkshire, where his father was an agricultural labourer, on October 28 (according to another authority, November), 1728. After a meagre education, Cook was apprenticed at the age of thirteen to a haberdasher at Staithes, 10 miles north of Whitby. After a short experience of this life, he was bound apprentice to Whitby ship-owners, and spent several years in the coasting and Baltic trade. In 1755 he entered the royal navy as an able seaman, and in four years rose to the rank of master. For about ten years after this he was mostly engaged in surveying about the St Lawrence and the shores of Newfoundland, and the results as embodied in his sailing directory (1766-78), are of value even at the present day. During this period he devoted himself to the study of mathematics, and otherwise qualified himself for the highest rank in the navy. In 1768 he was raised to the rank of lieutenant, and placed in command of the *Endeavour*, appointed to convey the expedition for the observation of the transit of Venus in the Pacific. The *Endeavour* sailed on August 25, and arrived at Tahiti in the following April, the transit being successfully observed on June 3. On the return, New Zealand was for the first time circumnavigated, and its coasts charted; the east coast of Australia was surveyed and taken possession of in the name of Great Britain. The strait which separates Australia from New Guinea was sailed through, and the distinction of those two islands established beyond doubt. Continuing his voyage by Java, Batavia, and the Cape of Good Hope, Cook anchored in the Downs on June 12, 1771. One important result of the voyage was to disprove the existence of the 'great southern Continent,' which had been supposed to extend from the Antarctic as far north as 40° S. Cook was promoted to the rank of commander, and given the command of a

second voyage of discovery in the *Resolution* and *Adventure*, which sailed from Plymouth, July 13, 1772. This expedition was out for three years. The great object was to discover how far the lands of the Antarctic stretched northwards. For this purpose Cook sailed round the edge of the ice, and penetrated as far south as possible, his farthest south point being 71° 10', in long. 110° 54' W. During the intervals between the Antarctic voyages, Cook cruised in the Southern Pacific, visiting Tahiti, exploring the New Hebrides, discovering New Caledonia, and many of the island groups in the Pacific. Plymouth was reached on July 29, 1775. One important feature of the second voyage was that, owing to the precautions taken by Cook, there was only one death among his crews during all the three years—a marked contrast to the fearful losses sustained during other voyages of this period.

Cook, who had been promoted to captain, and received an appointment in Greenwich Hospital, had scarcely been home for a year before he was appointed to the command of another expedition, the main object of which was to discover a passage round the north coast of America from the Pacific. Cook sailed from Plymouth in the *Resolution*, July 12, 1776, followed by Captain Clarke in the *Discovery*. Leaving the Cape on November 30, the expedition visited Tasmania and New Zealand, and spent the year 1777 cruising among the Pacific Islands. In the beginning of 1778 the Sandwich Islands were discovered, when Cook made for the west coast of North America. This he followed and surveyed from 45° N. as far as Icy Cape on the inside of Behring Strait, where he was compelled to turn back, reaching Karakakoa Bay in Hawaii, Sandwich Islands, January 17, 1779. At first the expedition was treated in the most friendly way by the natives. For some reason their attitude changed, and on February 14, when Cook landed with a party to recover a stolen boat, the natives set upon them with sudden fury, Cook being clubbed and stabbed to death at the edge of the water. Part of the body was recovered and buried, and in 1874 a monument was erected near the spot where he fell. Many varied accounts have been given of Cook's death, and many reasons adduced for the changed attitude of the Hawaiians; but the probability is that he simply fell a victim to a sudden outbreak of savage fury. Cook did more than any other navigator to add to our knowledge of the Pacific and the Southern Ocean; his observations have stood the test of modern investigations; in character he was honest and just, both to his own men and to the natives with whom he came into contact, and who almost invariably became greatly attached to him. A pension of £200 was granted to his widow (whom he married in 1762), and £25 to each of his three children. There are several editions of Cook's voyages. An account of the first voyage originally appeared as vols. ii. and iii. of Hawkesworth's *Voyages* (1773); the narrative of the second was written by Cook himself, 2 vols. with 1 vol. of plates (1777); that of the third appeared in 3 vols. and an atlas (1784), partly by Cook and partly by Captain James King. See Kippis's *Life and Voyages of Captain James Cook* (1788, reprinted 1883), and Professor J. K. Laughton's article in the *Dictionary of National Biography* (vol. xii. 1887).

Cook, JOSEPH, lecturer and author, born at Ticonderoga, New York, in 1838, graduated at Harvard and Andover, and after three years' preaching went to Europe in 1871, where he studied in Germany, and made a tour of the Mediterranean countries. In 1873 he commenced a series of 'Monday Lectures' in Boston, which, endeavouring to harmonise science and religion,

and discussing social and political questions, became very popular; and in 1880 he began an extended lecturing tour around the world. Besides his lectures, he has published a number of works on such subjects as *Biology* (1877), *Hereditry* (1878), *Marriage* (1878), *Labor* (1879), *Socialism* (1880), &c.

Cook, THOMAS, railway excursion and tourist pioneer, was born at Melbourne, Derbyshire, November 22, 1808. His educational advantages were few, and his early days were spent in gardening pursuits, and then in wood-turning and cabinet work. In his twentieth year he became a village missionary, and whilst thus occupied his sympathies were actively enlisted in the cause of temperance and free trade. But from 1841 his time and toil were engaged chiefly in the initiation and promotion of railway excursions. His first trip was from Leicester to Loughborough in 1841, his aim being the furtherance of the temperance cause. The Midland Railway was for some years the centre of his operations, and the town of Leicester his home. In spite of the great difficulties that had to be encountered, the business grew until not only in Great Britain, but throughout the world, agencies have been established, and the tourist tickets of Thomas Cook & Son are found everywhere. In connection with the late wars in Egypt and the Soudan, the English and Egyptian governments were largely aided by their enterprise; and the firm undertake on behalf of the Indian government the conveyance of Mohammedan pilgrims from India to Mecca.

Cooke, GEORGE FREDERICK, actor, born in Westminster in 1756, made his first public appearance at Brentford in 1776, and in the period between 1784 and 1800 became very popular in the English provinces and in Ireland, attaining a front rank in his profession, in spite of drinking habits that increased with his years. From 1801 to 1810 he played at Covent Garden both in comedy and in tragedy, and rivalled Kemble in the public favour; although here, also, from 1803, when he was hissed off the stage for drunkenness, his intemperance was a notorious thing, and a matter for jesting apology. His best characters were Richard, Shylock, Iago, Sir Giles Overreach, and Sir Pertinax MacSycophant. In 1810 he visited America, and appeared before enthusiastic audiences in the chief northern cities, where admiration for the actor secured indulgence and pity for the extravagances of the drunkard. He died in New York city, 26th September 1811; a monument marks his grave, erected in 1821 by Edmund Kean, who regarded Cooke as the greatest of actors. See his *Life* by William Dunlap (Lond. 1813).

Cooke, SIR WILLIAM FOTHERGILL, electrician, born at Ealing in 1806, served in the Indian army from 1826 to 1831, and after studying medicine at Paris and Heidelberg, abandoned this for telegraphy, and in 1837 entered into partnership with Professor Wheatstone. After experiments on various railway lines, they patented the single needle apparatus in 1845. In 1846 Cooke formed a company, which paid £120,000 for the partners' earlier patents. In 1867 Cooke and Wheatstone received the Albert gold medal; Wheatstone was knighted in 1868, and Cooke in 1869. He died 25th June 1879.

Cookery. The art of cookery, like other arts and handicrafts, is one which cannot be taught in an encyclopædia article, but the general principles which underlie the operations of cookery may be briefly expounded. This part of the subject—the chemistry and physics of cookery—has been much neglected until very lately.

The chief agent in cookery is heat, and therefore

a large part of our subject is the consideration of the chemical and physical changes which occur in food materials when subjected to the agency of heat. We may apply this agent either by bringing the food into direct contact with the source of heat, or by exposing it to radiations from the source of heat. Roasting, toasting, grilling, and to a partial extent, baking, are examples of the latter; while stewing, frying, and the so-called 'boiling' of food—i.e. immersion in hot water—are examples of heating by contact. The term 'boiling' is commonly misapplied in a manner that leads to confusion of ideas. Thus we speak of boiling a leg of mutton, boiling fish, boiling potatoes, &c. quite improperly. The food in question is not boiled, should not be boiled; it is merely immersed in water, which is conveniently used as a heating agent. As will presently be shown, even the water itself should not in most cases boil. Frying, properly conducted, is another example. Here a bath of fat is used to convey the heat.

What are the changes effected on the food by the action of cookery? is the fundamental question to be answered in treating cookery as a branch of applied science. What is the difference between a raw and a cooked potato? What is the difference between a raw and a cooked leg of mutton? and other such questions throughout. We all know the difference in flavour, but the chemical and mechanical changes are but little understood. To answer these questions we must first know something of the composition of the uncooked viands.

For this purpose the old-fashioned division of the elements of organic substances into proximate and ultimate is very convenient. The ultimate elements—carbon, oxygen, nitrogen, hydrogen, &c.—are not cookable, and in their uncombined state do not concern our subject; but the proximate elements, or more properly proximate constituents, such as albumen, gelatin, starch, cellulose, &c., are altered, and the whole subject will be best understood by considering separately the alterations which occur to these in the course of cookery.

Taking first the constituents of vegetable food, the largest of these is the material of the cell walls of the vegetable, *cellulose*, or woody fibre. The next in quantity, as existing in ordinary articles of food, is *starch*, or *fecula*, or *farina*. Both of these are carbohydrates—i.e. compounds of carbon with water, or the elements of water, and they contain these elements in the same proportions, but their structure and digestibility are very different. Starch in its raw state consists of small granules (see **STARCH**) which, placed in cold water, sink to the bottom without any degree of solution or other change by union with the water. In this condition they are practically indigestible in the human stomach, but when cooked, starch is the most easily digestible of all human food.

The changes that take place in the cookery of starch are considerable. If pure starch (arrow-root is such) be placed in water raised to the temperature of 140° F., the granules swell considerably, and the mixture becomes pasty or viscous. A little stirring breaks up the distended granules, and we obtain a glairy paste such as used by the laundress, and seen in cooked arrow-root. If the heat be now raised from 140° to the boiling-point, and the boiling continued, the gelid mass becomes thicker and thicker; and if there are more than 50 parts of water to 1 of starch, a separation takes place, the starch settling down with its 50 parts of water, and the excess of clear water standing above. We have here a case of hydration or combination with water as the result of cookery, and the probable cause of the improved digestibility. Dry starch may be raised to 300° without becoming thus semi-soluble.

The hydrate once formed may be dried by evaporation, and still retains some water and the same degree of solubility. Many farinaceous preparations, such as corn-flour, &c., consist chiefly of starch in this condition. This, however, is not the limit of starch cookery. If it is heated to about 400°, it is converted into *dextrin*, which is completely soluble in water at all temperatures, the solution being mucilaginous but not pasty. Dextrin differs from starch in other properties (see DEXTRIN), but is composed of the same elements in the same proportions, $C_6H_{10}O_5$ —i.e. six equivalents of carbon to five of water, or its elements. This change of starch into dextrin is of great practical importance as an operation of cookery, inasmuch as it anticipates the first stage of the digestion of starch.

The saliva, the pancreatic juice, and one of the intestinal secretions contain a peculiar principle which has received the name of *animal diastase*, from its resemblance to the diastase of malt. This converts the starch of food into the completely soluble dextrin, a change absolutely necessary for its assimilation as nutriment. In some animals the supply of this is so small that starch is almost worthless to them as food. It passes through the body unaltered. Such is the case with the carnivora. Human infants, when suddenly deprived of their mother's milk, have not sufficiently developed the power of salivary, pancreatic, and intestinal secretion of diastase to digest starch, and therefore demand assistance. Such assistance may be afforded by carrying the cookery of starch to what we venture to call the second stage—viz. its complete or partial conversion into dextrin. Thus, ordinary flour or oatmeal, simply heated in boiling water or milk, is merely subjected to the first stage—viz. hydration of the starch; but if the flour or oatmeal be well *baked*, a considerable proportion of its starch is converted into dextrin. A knowledge of this is of great importance to mothers, and also to nurses preparing food for dyspeptics, as adults vary greatly in their powers of diastatic secretion.

The reader will now understand why bread is rendered more digestible by toasting, and why crust of bread is more digestible than the crumb, in spite of greater hardness. In the ordinary baking of bread a variable amount of the starch is converted into dextrin. Well-baked bread is more digestible than under-baked. In the cookery of oatcakes, bannocks, scones, and all kinds of biscuits, this should be understood. The writer enjoys the luxury of hot rolls without their indigestibility, by simply moistening stale crusts of bread and reheating them in a kitchen oven. They thus become softened like new bread, and more digestible than before on account of the dextrinisation of a larger proportion of the starch. Baked and fried potatoes have a similar advantage.

The diastase of malt (see MALT) may be used for the dextrinisation of farinaceous food by adding malt flour or extract of malt to it; or the grain itself may be malted. The temperature at which malt diastase acts most vigorously is about 140°. At lower temperatures it acts more slowly; at much higher, its curious property is destroyed. To illustrate its action, make some oatmeal porridge very thick, then add about $\frac{1}{2}$ th part of dry malt flour at about 140°, and stir. In a few minutes the thick pudding becomes quite sloppy owing to the greater solubility of the dextrin into which the starch has thus been converted.

The cellulose—i.e. the stalks and the cell walls, such as the fleshy part of leaves, &c.—are more or less digestible, according to their looseness of structure and their interfluidity or succulent character. Thus we may digest a raw lettuce more easily than a raw cabbage, or the inner leaves of either more

readily than the outer leaves or stalks. The action of cookery on cellulose appears to consist in the loosening of its fibres, and rendering them more soluble. It is therefore advantageous that the water in which green vegetables, such as cabbages, are cooked should boil vigorously, the agitation of the steam bubbles assisting in the loosening of the fibres. Cellulose, like starch, may be converted into dextrin and sugar by the combined action of moderate heat with moisture and an acid. This change is aided by a little diastase. Sawdust and old rags may thus be converted into digestible and nutritious food, but not with commercial profit *at present*. An example of such conversion in Nature's laboratory is afforded by the ripening of a pear. Many varieties which are hard, woody, and sour when full grown in autumn, become gradually softer and sweeter, and finally delicious by simple storage. The action of *ensilage* (see ENSILAGE) of cattle food probably includes some degree of such conversion of cellulose.

The nitrogenous constituent of grain, the *gluten*, is not so greatly altered by cookery. The writer's investigations of this neglected subject lead him to the conclusion that the alteration which does occur is that of a partial hydration rendering the gluten more soluble, but this hydration is not so decided and definite as in the case of starch. There is one constituent of vegetable food which demands no cookery. This is pecten (otherwise pectose and pectin)—i.e. vegetable jelly. It exists most abundantly in fruits, and is familiar to all in the form of currant jelly, apple jelly, &c., which are pecten plus sugar. The cookery of vegetable casein will be discussed with that of the casein of milk.

Of the proximate elements of animal food the most abundant is gelatin; it constitutes about half the weight of the body of most animals. It exists in two forms—soluble and insoluble. Its cookery consists in the hydration of the insoluble form and rendering it soluble, as in the stewing of bones, tendons, skin, &c. in a stock-pot until their gelatin becomes soluble jelly. The muscular fibre itself, which with its enveloping membranes forms lean meat, is subjected to a similar change, but less completely, in the course of cookery.

The cookery of *albumen* differs materially from any of the preceding. Albumen exists in raw flesh meat as one of its juices, being a glairy liquid which is distributed between the muscular fibres and the joints, and around the bones, forming a lubricant, and probably conveying material of growth and renewal. It is typically seen in the white of eggs. When heated to about 134°, white fibres begin to appear within it. If the heat is continued, and gradually increased, they increase, until at about 160° the whole mass becomes white and nearly opaque. It is now coagulated into a tender, delicate, jelly-like substance, easily digestible and highly nutritious. If the heat is further raised, it becomes harder and harder, up to 212°. If this heat is continued, it shrinks, and becomes tough and horny, losing some of its water of composition, and its easy digestibility.

Ignorance of these particulars, and further ignorance of the fact that water has the same temperature, whether 'simmering' or boiling violently, causes the spoiling of vast quantities of food and wasting of much fuel in this country. The cooking temperature for all animal food is from 160° to 180°. When maintained for any length of time at the temperature of boiling or 'simmering' water, it is spoiled. To prove this, take a beefsteak and cut it in half. Place one half in water in a common saucepan, and boil or 'simmer' it for half an hour or more. Place the other half in water in an open-mouthed jar (such as a gallipot), and

place the jar in a saucepan of water so that only the outer water shall boil; cook it thus, and compare with the first. At a continued temperature of 212° not only does the albumen become toughened, but the gelatin also becomes dehydrated, hardened, and indigestible. All stewing operations should, therefore, be conducted at 30° or 40° below the boiling-point. When the exposure to a higher temperature is but for a short period, little or no mischief is done. This is the case in frying and grilling of animal food. These operations should always be rapidly conducted.

Besides the above-named constituents of animal and vegetable food, there are the saline juices necessary for supplying the saline constituents of the blood, and upon which the flavour of food largely depends. These are not altered by cookery, but are too frequently sacrificed. Potatoes, for example, contain a certain proportion of potash salts. The writer has examined the water in which potatoes have been cooked and that which is condensed when they are steamed, and finds that if the potatoes are peeled, a large proportion of the salts pass into the water. If they are cooked 'in their jackets,' much less is lost; but when baked or fried, all is retained. The complete retention of the juices is one of the reasons why roasted and grilled meat has more flavour than that which is cooked in water.

The changes which cookery effects on fat appear to consist in partial dissociation of its proximate elements. It is composed of a fatty acid combined with glycerine. These are partially separated by heat.

Another constituent of both animal and vegetable food is *casein*. It does not exist in the flesh of animals, but is an important component of milk; is the solid basis of the curd which is separated by the action of rennet or acids (see *CASEIN*). It also exists in peas, beans, and other seeds of leguminous plants. It is highly nutritious. There are two forms of casein—the soluble and insoluble. It is soluble as it exists in milk, but insoluble after precipitation by acids or rennet, as in making cheese. An infant that digests the casein of milk cannot digest it after separation as cheese.

The writer has succeeded in partially reconvert-ing the insoluble to the soluble form by adding bicarbonate of potash in the proportion of $\frac{1}{4}$ th to $\frac{3}{4}$ l of an ounce to 1 lb. of cheese; the potash dissolved in about a teacupful of water, and the cheese, grated or sliced, added to the solution, which is boiled until the cheese dissolves, forming a custard-like result. This may be added to oatmeal porridge and a multitude of other preparations. The theory upon which this method of treating cheese was founded is, that the curdling of milk is due to the combination of an acid with the natural alkali of the soluble casein, chiefly consisting of potash. The artificial addition in the proportion named not only renders the cheese more digestible, but restores the saline constituent of the original milk, which in the course of cheese-making, passed into the whey. The importance of thus rendering cheese more digestible, and supplying its saline dietetic deficiency, will be understood by the fact that 20 lb. of cheese contain as much nutriment as a sheep weighing more than 60 lb. Lean beef and mutton contain from 72½ to 73½ per cent. of water, cheese about 30 per cent. and no bone. Cheese may be stored and carried almost as easily as coal.

A multitude of cookery books exist, too many to name. These consist mainly of instructions in the preparation of particular dishes. The philosophy of cookery has a very limited literature. In the third, sixth, and tenth essays of Benjamin Thompson, Count Rumford (1796), *The Chemis-*

try of Cookery, by W. Mattieu Williams (1885), and Cantor Lectures on *The Scientific Basis of Cookery*, by the same author, the subject is treated as a branch of applied science. Count Rumford's essays also include his remarkable achievements in economic feeding of the poor in Munich, and his improvements of cooking apparatus. Of late, much more attention has been bestowed on cookery in Great Britain, and the board-schools in the principal towns now make provision for instructing their girl pupils in this important subject. The processes of roasting, stewing, &c. will be treated under their respective titles. See also *DIET, DIGESTION*, and the articles on *BRILLAT-SAVARIN* and *SOYER*.

Cook Islands, otherwise known as the Hervey Archipelago, lie about midway between the Society and Navigator groups, near 20° S. lat., and 158° W. long., and are some volcanic, some coralline. The principal members of the cluster are Mangaia, Ation, and Raratonga. The natives, mainly of the brown Polynesian stock, are about 10,000 in all, of whom 6000 are in Raratonga, which is mountainous but fertile. Formerly cannibals, they are now all Christians, and dress after the European fashion. The islands were annexed by Britain in 1888.

Cook, MOUNT, the highest peak of Australasia, is one of the Southern Alps near the centre of the range, on the western side of the South Island of New Zealand. It is 12,349 feet high, is covered with perpetual snow (the snow-line being 3500 feet lower than in Switzerland), is difficult of access, and was scaled for the first time by the Rev. W. S. Green on 2d March 1882.

Cookstown, a town in County Tyrone, Ireland, 53 miles W. of Belfast by rail, with manufactures of linen, and bleach-works. Pop. 3870.

Cook Strait, discovered by Captain Cook on his first voyage, separates the north and south islands of the New Zealand group, and varies from 20 to 80 miles in width.

Cooktown, on the extreme north of Queensland, 1050 miles NW. of Brisbane, already one of the chief ports of the colony, though only founded in 1873. It is built along about 1½ mile of the southern bank of the Endeavour River, and is almost environed by hills. There are already handsome banks, schools, and public buildings. Pop. 5000. Near there are gold-diggings and tin-mines, pearl-fisheries, and fisheries of trepang. Here Cook landed in the *Endeavour* for repairs in 1770.

Cooler. See *BEER, REFRIGERATOR*.

Coolies (Hind. *kālī*, 'labourer'), Indian and Chinese labourers who emigrate to foreign lands, whether at their own charge, thus becoming free competitors in the open labour market, or at the expense of the foreigner whom they bind themselves by contract to serve for a fixed term of years. This definition does not quite cover the whole use of the word. Labourers who migrate from one part of India to another, as for instance from Bengal to Assam, are called coolies. The European and American residents in the treaty ports of China give the same name to the lower class of Chinese labourers in their service.

The natives of India having a strong repugnance to crossing the ocean, free coolie emigration is almost entirely Chinese. Although until recent years emigration from China was illegal, and the strong ties of family affection, the love of country, and ancestral worship, made it unpopular, the pressure of population produced a continual outflow during the last and the present century, chiefly from the provinces of Fuh-Kien and Kwangtung. The emigrants swarmed over the archi-

pelago, settled by thousands and tens of thousands in Java and in the Straits Settlements, and threaten eventually to displace the natives in Siam and the Malay Peninsula. The discovery of gold attracted large numbers of Chinese to California and Australia. The first railway across the Rocky Mountains was partly made by Chinese labour, and M. Lesseps invites their help for the excavation of the Panama Canal. In spite of his utility, the coolie has become an intolerable offence to the working-classes of America and Australia. He is accused of gambling, opium-smoking, and immorality; but the head and front of his offending is his working for low wages, and lowering the market value of labour. In 1881 the United States negotiated a treaty with China, by which restriction of Chinese immigration was secured to the States in return for American prohibition of the opium trade on the coast of China. Another treaty between the two powers in 1888, prohibiting the entry of Chinese labourers into the United States for a period of twenty years, has been refused ratification by the Peking government. In British colonies the attempt has been made to exclude the obnoxious coolie by the imposition of a poll-tax. The legislature of British Columbia passed an act in 1884, by which every Chinaman was obliged to take out a license, and pay a fee of \$10. A Chinese, named Wing Chong, refused to pay the fee on the ground that the act was unconstitutional, and an infraction of the existing treaties between Great Britain and China. A judge of the Supreme Court of the colony decided in Wing Chong's favour, and though the colonial government initiated an appeal to the Privy-council, they failed to prosecute it; so the act became a dead letter. In Australia, similar acts, though quietly submitted to, failed to secure the desired end, Chinese immigrants continuing to arrive, in spite of the heavy poll-tax of £10 a head. In 1888 the New South Wales legislature passed an act to prohibit the landing of Chinese immigrants; but this case also the law-courts decided against the legislature. At a conference of delegates from the governments of all the Australian colonies, it was unanimously agreed to endeavour to secure the exclusion of the Chinese, through the negotiation of a new treaty between the British and Chinese governments. The existing treaties which promise protection to the Chinese immigrant are the Treaty of Nanking (1842), the Treaty of Tientsin (1858), and the Convention of Peking (1860).

The coolie in the United States and in some British colonies is an uninvited and unwelcome visitant. At the same time his services have been eagerly sought in other colonies, the governments and planters of which have borne all the expenses of his passage, paid him a small advance, and in addition paid head-money to the agent who obtained him. To recoup this expenditure, the planter required the coolie to bind himself to serve for a term of years at a fixed rate of wages. Coolies thus indentured occupy a similar position to apprentices, soldiers, and sailors. Theoretically the system is quite justifiable, but practically it has shown itself liable to the grossest abuse. The dark story of coolie emigration to Peru and Cuba, carried on from Macao (q.v.), rivals in atrocity the horrors of the slave-trade and slavery. This branch of the coolie traffic was brought to an end in 1873 by an enactment of the Chinese government, requiring that in the contract a clause should be inserted securing to the coolie a free passage home at the expiration of his term. The planters were not willing to incur this obligation; and coolie emigration from Chinese ports ceased. During the years between 1847 and 1873, there was a fearful loss of

life, some perishing on shipboard in vain attempts to recover their liberty, others dying of ill-treatment or disease, or by suicide. The only redeeming feature in this sad business was that some time or other it came to an end. The slave was a slave until death: the coolie could look forward to the end of his contract. In 1878 Consul-general Cowper reported to Lord Salisbury that out of 116,267 coolies actually landed in Havana, about 50,000 were then in Cuba.

Coolie emigration under contract to British and French colonies is mainly Indian, with a small percentage of Chinese in its ranks. Both the Indian and the colonial legislatures have taken great pains to prevent abuse of the system, and with considerable success, although there is evidence that constant watchfulness is necessary. Every step of the process, from the first solicitation of the labourer, until the ship carries him out of port, is regulated by the Indian government. The agents who collect the coolies, the depôts where they are lodged, the contracts they sign, the ships in which they embark, are inspected, licensed, supervised by government. Protectors of emigrants are appointed in Calcutta, Madras, and Bombay, from which ports only the emigration is lawful. In like manner the colonial governments have enacted regulations and appointed protectors, to secure to the coolie limitation of his task, sufficient food, suitable lodging, and medical care in sickness. The imperial government has intervened by conventions entered into with foreign governments, with France in 1861, with the Netherlands in 1870, to secure the fair treatment of the coolie in foreign colonies. That all this legislation is neither unnecessary nor unfruitful is proved by the case of Réunion. In 1880 M. Rougon reported to the French government that the coolies in this island 'were badly clothed, badly fed, badly paid, and badly cared for when sick.' The Indian government receiving similar reports, put in force a provision of the Emigration Act, and prohibited emigration to Réunion. The British consul at Cayenne reported that the coolies in French Guiana suffered 'barbarous and inhuman treatment;' and in 1876 emigration to that colony was stopped. According to the Indian Emigration Act of 1883, at present in force, emigration under contract is lawful to the following places: British colonies—Mauritius, Jamaica, British Guiana, Trinidad, St Lucia, Grenada, St Vincent, Natal, St Kitts, and Fiji; French colonies—Martinique, Guadeloupe; also to Dutch Guiana, and the Danish island, St Croix. In 1886 the Jamaica government suspended immigration from China and India to that colony. In Trinidad the coolies, about 55,000, are one-third of the population. They are usually well fed, not overworked, and are well treated in sickness. A large proportion elect to remain in Trinidad when they are entitled to a passage back to India; and of those who go, a large number take sums of money with them, and not a few, having gone back to India, return again to Trinidad. Some coolies, too, remain on particular estates for many years. Occasional cases of injustice or ill-treatment no doubt occur, but on the whole the coolie is well used (Governor Norman's report, 1885). On the other hand, there are unfavourable reports from Mauritius, where the Indian coolies number in round figures 150,000. There are about 25,000 in Natal, 13,000 in Jamaica, and 70,000 in the French colonies.

Coolie contract labour in India is regulated by the Inland Emigration Act of 1882, which relates to 'emigration from other parts of India to the labour districts of Bengal and Assam.' Its provisions are similar to those of the Indian Emigration Act of 1883. Every possible precaution which a government can take appears to have been taken;

nevertheless complaints of unfair and even cruel treatment of the coolies are heard from time to time. The coolie traffic between the southern ports of India and Ceylon is constant and mutually advantageous; about 70,000 go from India every year, of whom three-fourths return, and the rest settle in the island.

The islands of the Pacific have been the scene of a so-called labour trade, in respect to which Sir Arthur Kennedy, governor of Queensland, wrote in 1881: 'I have never concealed my opinion of the traffic in Polynesian savages, and I feel assured that scandals exist which do not reach the public. . . . I have had many years' experience in the West African slave-trade and the Chinese coolie-trade, and I cannot divest myself of grave fears that the Polynesian labour-trade partakes of many of the evils of both.' A Royal Commission of Inquiry was appointed in 1884; the existence of kidnapping was proved; and 404 kidnapped islanders (called 'Kanakas') were restored to their homes.

The literature of this subject consists chiefly of parliamentary papers and government reports. Besides those referred to above, the following may be named: Correspondence, Papers, or Reports on the Macao Coolie Trade (1871 to 1875); on Coolie Emigration from India (1874); on the Coolies in Assam (1867), in Surinam (1877), in Trinidad (1885); on Coolie Importation from India to French Guiana (1878); and on Chinese Immigration into the Australasian Colonies (1888). *The West Indies and Spanish Main*, by A. Trollope (1860); *The Coolie: his Rights and Wrongs*, by E. Jenkins (1871); *In Quest of Coolies*, by J. L. A. Hope (1872); Charles Kingsley's *At Last* (1872), and Churchyard's *Blackbirding in Southern Seas* (1888), may be consulted.

Coomassie, the capital of the kingdom of Ashanti, Western Africa, is situated about 120 miles NNW. of Cape Coast Castle. It occupies the side of a rocky hill, and is about four miles in circuit. The walls of the houses are mostly formed of stakes and wattle-work, the interstices being filled up with clay; the roofs are of palm-leaves. The king's palace was burned by Wolseley in 1874, but has been rebuilt (see ASHANTI). Pop. stated by natives to be 100,000; but other reports, including observations during the war, say 20,000. See Reade's *Coomassie* (1876).

Cooper, ASHLEY. See SHAFTESBURY.

Cooper, SIR ASTLEY, surgeon, was born, a clergyman's son, at Brooke Hall, Norfolk, 23d August 1768. In his seventeenth year he went to London, and became a pupil of Mr Cline, one of the most noted surgeons of his day. He devoted himself with ardour to his profession, and was a constant attender at the dissecting-rooms, and also at the lectures of the famous John Hunter. In 1789 he was appointed demonstrator of anatomy at St Thomas's Hospital; and two years after he assisted in the lectures on anatomy and surgery. In 1793 he was appointed lecturer on anatomy at the College of Surgeons, in 1800 surgeon to Guy's Hospital; and in 1813 professor of Comparative Anatomy in the College of Surgeons. Meanwhile, Cooper had been enriching medical literature by various contributions. An essay on the effects resulting from the destruction of the *membrana tympani* gained him, in 1802, the Copley medal of the Royal Society, of which he was elected a fellow three years afterwards. In 1804-7 appeared his great work on *Hernia*, with life-size illustrations, a contribution of the utmost value to medical science, though in a pecuniary point of view it proved very unprofitable to himself. The practical part of his profession was not neglected during this time. He was the first to attempt the tying of the carotid artery, an attempt which, though unsuccessful in his hands, has since proved effectual in the hands of other practitioners. His annual income, which in the

fifth year of his practice only amounted to £100, had in 1813 risen to the enormous sum of £21,000. In 1817 he tried what has been considered the boldest experiment ever attempted in surgery, the tying of the aorta, which did not prove successful. In 1820 Cooper removed a tumour from the head of George IV., who conferred a baronetcy upon him some six months after. In 1827 he was elected President of the College of Surgeons, in 1828 became sergeant-surgeon to the king, and in 1830 was made vice-president of the Royal Society. Other honours flowed in upon him. He was made a member of the French Institute, and corresponding member of the Royal Academy of Sciences, a D.C.L. of Oxford, and an LL.D. of Edinburgh. Ever busy with his pen as with his knife, he in 1822 published a great work on *Dislocations and Fractures*. His treatise on the *Anatomy and Diseases of the Breast* (1829-40) was characterised by all the care, research, and originality which distinguished his previous works; so likewise was his *Anatomy of the Thymus Gland* (1832). Cooper died 12th February 1841, and was buried in the chapel of Guy's Hospital. A colossal statue to his memory is erected in St Paul's Cathedral, London. As a teacher, Cooper possessed the faculty of communicating knowledge in a manner at once easy and agreeable; and he elevated medical surgery, the operations of which before his time had been described as a series of 'frightful alternatives, or hazardous compromises,' into a science. See his *Life* (2 vols. 1843).

Cooper, JAMES FENIMORE, an American novelist, was born at Burlington, New Jersey, September 15, 1789. His father, a man of wealth and Federalist member of Congress, was of Quaker descent. Copyright 1889 in U.S. by J. B. Lippincott Company. In 1790 the family removed to Cooperstown, New York, then in a wild frontier region of great natural beauty. Cooper entered Yale College in 1802, a boy of thirteen. After remaining there three years, he was dismissed for some minor act of alleged misconduct. In 1806 he shipped as a common sailor, and in 1808 entered the navy as a midshipman. He rose to the rank of a lieutenant, but in 1811 resigned his commission, and married Susan, a sister of Bishop De Lancey of New York. His first novel, *Precaution* (1819), was a failure; and the thirty-two tales which followed it were of extremely unequal quality. Among those which had signal merit we may name *The Spy* (1821), *The Pilot* (1823), *The Last of the Mohicans* (1826), *The Prairie* (1826), *The Red Rover* (1831), *The Bravo* (1831), *The Pathfinder* (1840), *The Deerslayer* (1841), *The Two Admirals* (1842), *Wing-and-Wing* (1842), and *Satanstoe* (1845). His other writings include a meritorious *Naval History of the United States* (1839; abridged edition, 1841), and *Lives of Distinguished American Naval Officers* (1846). His works of fiction have long enjoyed great popularity; and his best productions, in spite of conspicuous faults, well deserve all the favour they have received. His sea-tales and stories of frontier life are in all respects his best. Cooper's descriptive talents were of very high order; and some of his characters, such as 'Natty Bumppo,' 'Long Tom Coffin,' 'Birch,' 'The Big Serpent,' and especially 'Leather-Stocking,' are drawn with as much strength and life as almost any in the whole range of fiction. The peace of many of the later years of his life was much disturbed by literary and newspaper controversies and actions for libel, in nearly all of which he was successful. He conducted his own lawsuits, and usually pleaded his own cases with admirable tact and ability. One good result of these suits was to put upon the newspaper press of his own time and country some degree of restraint from the scandalously savage and virulent freedom of speech

which then prevailed. On either side of the Atlantic Cooper's own severity of language won him no small amount of personal unpopularity; yet no man loved his own country better than he; and his high regard for the nobler side of the English character, and his appreciation of the grand achievements of British history, found frequent expression in his writings. These writings, other than the best of his novels, contained much to excite opposition, and they brought upon him, not altogether undeservedly, the reputation of being a proud, contentious, and somewhat wrong-headed man; yet there was in his real character much sweetness, as well as great strength, purity and dignity, and unqualified honesty. His pride was large, but it was not mixed with personal vanity. It has been well said that his faults were those of temper and judgment, rather than of character. He died at Cooperstown, September 14, 1851. The best biography is by Lounsbury (1882).

Cooper, PETER, manufacturer and philanthropist, born at New York, 12th February 1791, assisted his father in his successive occupations of hatter, brewer, and brickmaker, and served an apprenticeship to a carriage-builder, 1808-12. He next made independent ventures as a machinist, cabinetmaker, and grocer, and established a glue factory on Long Island. He erected large iron-works in Baltimore in 1828, and in 1830 constructed there, from his own designs, the first locomotive engine ever built in America. He afterwards built an iron-wire factory in New York, and large blast-furnaces in Pennsylvania; and he was largely instrumental in bringing about the laying of the Atlantic cable. To provide the working-classes with educational advantages, of which he himself had enjoyed so few, he erected and endowed the Cooper Union (1854-59), one of the most useful institutions in New York, where free lectures, reading-room, art collections, and technical schools have been provided. In 1876 he received the Independent nomination for president. He died in New York, 4th April 1883. See *Life* by Mrs Carter (1889).

Cooper, THOMAS, the Chartist poet, born at Leicester in 1805, was apprenticed to a shoemaker at Gainsborough, taught himself Latin, Greek, Hebrew, and French, and became a schoolmaster at twenty-three, and at the same time a local Methodist preacher. After reporting for some of the newspapers in the Midlands, he became leader of the Leicester Chartists in 1841, and was an active editor of tracts. He lectured in the Potteries during the riots in August 1842, was arrested on a charge of conspiracy and sedition, and sentenced to two years' imprisonment in Stafford gaol. Here he wrote *The Purgatory of Suicides*, a poem in the Spenserian stanza, and *Wise Saws and Modern Instances*, a series of tales, which were both published in 1845. Next year appeared his *Baron's Yule Feast*, a *Christmas Rhyme*, and a series of papers headed 'Condition of the People of England' in *Douglas Jerrold's Newspaper*. In 1848 he began to lecture on history and politics in London, and set up the *Plain Speaker* and *Cooper's Journal*, two short-lived penny weeklies. He published two novels, *Alderman Ralph* (1853), and *The Family Feud* (1854), and about the end of 1855 relinquished the sceptical opinions he had held since his imprisonment, and became an active lecturer on Christian evidences. In 1867 a number of his friends purchased for him and his wife an annuity of £100. Cooper published his *Autobiography* in 1872, and an edition of his *Poetical Works* in 1878.

Cooperage, the art of making vessels of pieces of wood bound together by hoops. It is a very ancient art, such vessels having been in use

among the Romans at the period of the Christian era. The upright pieces forming the sides of a barrel or cask, or other cooper's work, are called *staves*; and as casks are usually larger in the middle than at the top and bottom, this swelling, called the *belly* or *bulge*, is formed by skilfully shaping each stave so that it shall form part of the required double conoid, and that, when all are built and hooped together, their edges shall coincide perfectly; for this purpose each stave is made broadest in the middle, and narrowed down in a curved line towards each end. A skilful cooper can work this curve so accurately, that no further fitting or alteration shall be needed when the staves are put together. The staves are made to meet at their inner edges, and by driving the hoops very hard, the inner part is compressed until the slight gaping outside is closed, and thus slight inaccuracies of fitting are remedied.

There are several branches of cooperage. The *wet* or *tight* cooper makes vessels for holding liquids. The *dry* cooper does inferior work, such as barrels for containing dry goods, where an inferior degree of accuracy is sufficient. The *white* cooper makes churns, pails, &c., which for the most part have straight sides.

The best work is made of oak, which must be thoroughly dried before being put together. In warm countries, the drying of the sun is sufficient, and casks are therefore mounted in summer only; but in Britain, artificial drying is commonly resorted to. The hoops are hammered down from the narrow to the wide part of the cask, by means of a mallet striking a piece of wood held against the hoop. Iron hoops are sometimes put on hot, in order that their contraction on cooling may bind the work together. Most ingeniously constructed machinery is now generally used in barrel-making.

Cooperage, on the North Sea, is that demoralising system of selling or bartering strong drink, tobacco, or other articles, to fishermen or sailors, from Dutch or other foreign vessels called *copers* (Ger. *kaufen*, Dut. *kopen*). They ostensibly cruise with the English fishing-fleets to sell foreign tobacco on which no duty has been paid, and what on shore would cost four shillings per pound is sold for eightpence. The trade began more than fifty years ago by foreign vessels from Dutch ports trading with English smacksmen in articles of clothing, which grew into the more profitable barter and sale of tobacco and spirits. An English smack, until the insurance company refused to insure her, has been known to take out £500 worth of grog and tobacco, and clear another £500 in two months in the traffic. To counteract the evils of the system, Mr E. J. Mather, in 1882, started a mission for the deep-sea fishermen, which in 1888 had at command eight mission ships, stored with good literature, woollen clothing, tobacco, and medicine, and a staff of twelve clergymen as honorary chaplains. The Customs Commissioners refused the necessary concessions for the sale of tobacco at a cheap rate in 1885, but granted the same in 1887, and now the ordinary drawings of a voyage may be £100 for tobacco. The Queen became the patron of the mission, and it is duly registered by the Board of Trade. As a result of an international conference at the Hague between the six fishing powers, a convention was signed in 1887, one of the provisions of which contemplated the absolute prohibition of the sale or barter of spirits on the North Sea. The North Sea Fisheries Bill (1888) gave effect (as far as Great Britain is concerned) to the recommendation of the convention. The sale of spirits to fishermen and others on board fishing-vessels is prohibited; fishermen are forbidden to buy spirits at sea; the exchange or barter for spirits of any article, especially the fish caught,

nets, or gear of the fishing-boat, is also prohibited. Vessels trading in provisions, &c. must be licensed, and penalties from £10 to £50 are exigible for offences against the convention. See E. J. Mather's *Norward of the Dogger* (1887).

Co-operation. In the social and economic sense of the word, co-operation generally means the association of work-people for the management of their own industrial interests, in store, workshop, or other undertaking, and the equitable distribution of profits among those who earn them. In Great Britain it has succeeded best in distribution, that is, in the form of co-operative stores for the supply of the domestic wants of the workmen's families; in Germany and Italy it has flourished chiefly under the form of people's banks, for furnishing mutual credit to workmen and also small tradesmen. Co-operative production has not yet made corresponding progress. The co-operative movement acquired vitality with the foundation of the Rochdale Society of Equitable Pioneers in 1844. Before that date there had been instances of co-operative industry among English miners, New England fishermen, and the Greek sailors of the Levant. In Great Britain there exist even yet co-operative societies, which were founded prior to 1844; one at Govan, said to have been established in 1777, and another at Hull, started in 1795. The earliest in England, however, was that founded in 1794 at Mongewell, in Oxfordshire, by Shute Barrington, Bishop of Durham. During the Owenite agitation from 1820 to 1845, the movement began to assume national importance, hundreds of societies rising up, which for the most part rapidly disappeared. By general consent it is agreed that the movement took practical and permanent form with the Rochdale Pioneers (1844). The founders were twenty-eight weavers, nearly all of whom were socialists of the Owen school and Chartists; and their original capital was £28, painfully collected by subscriptions of twopence, afterwards raised to threepence a week. With this capital they opened a store for supplying themselves with provisions, but at first they had only four articles to sell—flour, butter, sugar, and oatmeal. Their success, which was steady and rapid, was chiefly due to their device of limiting interest on shares to 5 per cent. and dividing profits among members in proportion to their purchases. By 1857 they had a membership of 1850, a capital of £15,000, and annual sales to the amount of £80,000. Their society, its organisation and methods of conducting business, became a model to the working-men in the north and centre of England, as also in Scotland. In this way the movement rapidly spread, and the societies are now over 1400 in number, with nearly a million members. In 1864 the Wholesale Society for the supply of commodities to the various stores was established at Manchester, and a second at Glasgow in 1869; but the two work in harmony, and may be considered as one institution. In 1871 the *Co-operative News* was started as the organ of the co-operators. Since 1869 national congresses of co-operative societies have been held every year in one or other of the large towns of Great Britain. These may be regarded as the annual parliaments of co-operators. The efforts after organisation culminated in the consolidation of the Co-operative Union with a regular constitution drawn up in 1873. Subject to the congress, the Union is governed by a United Board of twelve members, representing the six sections into which the union is divided. The sectional boards have monthly meetings of their own. The Central Co-operative Board, consisting of all the members representing the six sections, comes together for business only at meetings of congress.

Having thus sketched the general development

of English co-operation, we shall now more specifically indicate the rules and organisation of the societies. Any one may become a member on paying an entrance fee of one shilling, and members may pay up their shares at the rate of threepence a week. Shares are usually one pound each, and one or two of these shares, transferable but not withdrawable, constitutes all the capital a member is required to hold. The other share capital that a member may hold is withdrawable. The interest on capital is limited to 5 per cent. Goods are sold at the prices current among respectable shopkeepers in the neighbourhood, and after paying expenses the nett profits are distributed quarterly among the members in proportion to their purchases. These dividends may be allowed to accumulate in the store, but no member is permitted by law to hold more than £200. The general rule is that payments be made in ready money, a system to which co-operation largely owes its success, but which is not yet universal. At the congress of 1888 complaints were made that the credit system is to some extent permitted. Irrespective of the amount of his investments, each member has only one vote. The members elect a committee for the management of the business. The committees have frequent meetings, and control the employees of the store. *The members themselves hold quarterly and in many cases monthly meetings. The Wholesale Society is a federation of retail societies, which have to take up shares, and they participate in the management in proportion to their membership. The Wholesale is a large and growing organisation for the supply of goods to the various societies composing it, with purchasing and forwarding depôts not only in England and Ireland, but in New York, Hamburg, Copenhagen, Calais, and Rouen. It owns five steamships, which ply between England and the Continent. It has also extensive productive works, as boot and shoe factories at Leicester, soap-works at Durham, woollen-cloth works at Batley, &c. Besides the productive works thus conducted by the Wholesale Society, there are a number of societies for production alone, societies for working corn-mills, and a number of retail societies which carry on corn-mills and various branches of domestic production. The annual production by societies adhering to the Co-operative Union may probably be estimated at about £5,000,000. In addition to the societies already mentioned, there is a co-operative fire and life insurance society, and the *Co-operative News* Society, started in 1871 for carrying on the organ of the co-operators. It should also be mentioned that the societies spend considerable sums in education.

Statistics of English Co-operation, taken from the report of the Co-operative Congress for 1888: Connected with the Co-operative Union, were (in 1887) 1432 societies, with a membership of 945,619, a share capital of £10,012,048, and sales to the amount of £34,189,715, on which profits to the amount of £3,193,178 were made. In these figures, however, are included the returns of three Civil Service associations, which have joined the Co-operative Union. In 1888 the weekly circulation of the *Co-operative News* was 35,800. The above statistics show that nearly 1,000,000 families, or about one-sixth of the population of Great Britain have their wants in whole or in part supplied through co-operative stores.

Co-operation in England is thus already one of the established institutions of the country, the importance of which has been recognised alike by statesmen and economists. Though essentially a workmen's movement, it should be said that it owes much to the enlightened and philanthropic guidance of men of other classes, and Robert Owen,

Maurice, and Kingsley. Messrs Neale, Holyoake, Hughes, Ludlow, and the Marquis of Ripon have also powerfully aided in promoting it.

In the *United States of America* co-operation has not made such progress as might have been expected from the energy and spirit of initiative prevalent among the people. Though co-operation had previously existed among the fishermen of New England, the Brook Farm (q.v.) experiment may be regarded as the starting-point of the movement. Co-operative business in New England in 1886 reached the following figures: In distribution, £400,000; productive co-operation, exclusive of dairies or creameries, £170,000; creameries, £100,000; banks, £700,000—in all, about £1,400,000. In Philadelphia, co-operative building societies have provided the workmen with from 80,000 to 100,000 homes. The same form of co-operation flourishes in other parts of the country. A notable and thoroughly successful effort in productive co-operation has been made in the coopering trade at Minneapolis since 1874. In 1882 the students of the university of Harvard formed a co-operative society for supplying themselves with books, stationery, and other articles. The movement has been a success, and has been imitated by the universities of Yale and Michigan. The general result, however, of a study of co-operation in America is that while the experiments have been numerous, varied, and in many cases successful, its influence has been on a limited scale. The rewards offered to every kind of exceptional capacity in private enterprise are so enormous, the scope for the development of individual energy in all directions is still so great, that the workmen have not yet widely realised the necessity for industrial association among themselves. Many important firms have, however, successfully introduced the system of sharing profits with their work-people. Complaints are made that the laws of some of the states do not offer reasonable facilities for the formation of co-operative societies.

In *France* the industrial partnership system, by which the capitalist gives his workmen a share in his profits, has made greater progress than the co-operative movement properly so called. At the revolution of 1848 the government gave some scanty subsidies to co-operative production, but only a few of the societies prospered. Even yet co-operative stores, co-operative banks, and societies for co-operative production have only had a limited success.

In *Germany* co-operation has flourished greatly in the form of people's banks. These originated in 1849 under the auspices of Schulze-Delitzsch, at the little town of Delitzsch in Saxony. In 1885 there were 3822 societies belonging to the Schulze-Delitzsch system, of which 1965 were credit societies, 678 for distribution, 493 for the purchase of raw material, &c. The societies had an aggregate membership of 1,500,000, a share and reserve capital of £15,000,000, a loan capital of £25,000,000, and did an annual business of £150,000,000. Since 1859 they have held annual congresses. Schulze-Delitzsch was salaried counsellor (*amvult*) or general manager of the societies till his death in 1883. In 1885 there were 145 productive associations in Germany. While there were in 1873 only 6 co-operative dairies in Germany, there were 226 of them in 1885. In addition to all these, in 1884 there were 800 societies (called after Raiffeisen, their founder), whose function it is to provide mutual credit for the small farmers of Germany.

Austria had, in 1883, 1565 societies on the Schulze-Delitzsch system. In 1881 the kingdom of Hungary possessed 357 societies.

In *Italy* co-operation is making great progress,

chiefly in the form of people's banks. In 1883 there were 250 such banks. At the end of 1885 their number had increased to 423, with £2,500,000 of share capital and about £13,000,000 of loan capital. Co-operation in other forms also is rapidly making way. In 1885 there were about 250 co-operative dairies, and besides there are many co-operative bakeries, established with a view to checking the ravages of the Pellagra (q.v.) by the supply of wholesome bread. Such institutions receive the active support of the Italian government.

In *Belgium* the co-operative movement has established itself on a very considerable scale at industrial centres such as Ghent, in stores, bakeries, and in co-operative fisheries.

In *Denmark* co-operative dairies have recently been making wonderful progress (see DAIRY).

The various Professional and Civil Service stores are simply a result of the application of the co-operative system for the supply of the wants of the middle classes, especially the professional classes and clerks, begun in 1884; and these stores now do a very large business, the largest being the Army and Navy Stores in Victoria Street, London. The salient difference between this middle-class co-operation and that of the working-men is that the former admits of the system of privileged shareholders, whereas all the benefits of the latter are open to every one who pays an entrance fee of one shilling.

From the above facts it will be apparent that the purpose and tendency of the co-operative movement is that the workmen, through the principle of associated industry, by means of a joint capital, should equitably manage their own affairs so far as they can. Such management, we have seen, has been applied on a large scale to distribution and to people's banks, and has had a considerable success also in various forms of domestic production, as in corn-mills, bakeries, boot and shoe factories, dairies, &c. In the large and staple branches of manufacture it has as yet done very little. But so far as it has gone, the movement has been a real and effectual training for the intelligence, business capacity, and moral character of the workmen. It has taught them thrift, foresight, self-control, and the habit of harmonious combination for common ends; and it has opened up an unlimited field for peaceful, hopeful, and successful effort in the future.

See Holyoake's *History of Co-operation* (2 vols.), and his *Self-help a Hundred Years Ago* (1888); the reports of the Co-operative Congress; *Working-men Co-operators*, by A. H. D. Acland and B. Jones (1884); *Reports on Co-operation in Foreign Countries*, a blue-book issued in 1886; *English Associations of Working-men*, by Dr Baernreither (1888). See also *History of Co-operation in the United States*, published under the auspices of Johns Hopkins University (Baltimore, 1888).

Cooper's Hill, a ridge on the borders of Berks and Surrey, commanding a beautiful view of the Thames valley. It was the scene of a famous poem by Denham (q.v.), and is now known in connection with the Cooper's Hill College, an important institution established in 1870 for the education of engineers for the Indian Works Department, to which an important forestry school is attached.

Co-ordinates. See GEOMETRY (ANALYTICAL).

Coorg (a corruption of *Kodagu*, 'steep mountain'), a province under the government of India, lying below the western Ghats and Mysore. It contains 1583 sq. m. Pop. (1871) 168,312; (1881) 178,302. The capital is Merkara (pop. 8383). Coorg is mainly within the basin of the Kaveri River; a great part of its area is 3000 feet above the sea. The yearly fall of rain amounts to 122 inches, and hence the temperature is humid, but comparatively low and equable. Nearly the whole of this rugged

region is covered with forests, which form the main natural wealth of the country, though gold and iron are found. The natives, a branch of the Dravidian stock, speaking a language akin to Kanarese, are handsome and athletic mountaineers. Agriculture is limited to the valleys. Coffee (injured recently by disease), cardamoms, and cinchona are grown. Polyandry used to be the rule. Cairns and dolmens are common, and the country is intersected by earthen ramparts, which are from 15 to 25 feet in height, with deep ditches.

Coot (*Fulica*), a water-bird in the same family as the rails (*Rallidae*), and in the old order *Grallae*. The members of the genus are well marked by a scalloped fringe round the long toes, which thus show an approach to the webbed condition. The beak is straight and short, but expands in a curious swollen patch on the front of the forehead. The tail is very short. The coots are essentially aquatic, almost always afloat, and especially frequent still waters. They feed on water-plants and small animals. The European species generally migrate southwards in winter.

The Common Coot (*F. atra*) is widely distributed in Central and South Europe, and in Western Asia. It is about 16 inches in length, and has a

Common Coot (*Fulica atra*).

predominantly slaty black colour, with a narrow white band across the wings. The bill and the bald forehead expansion are bright white, the feet more or less green. Coots make a large rough nest of water-plants and stems among the rushes, or on a rock in the middle of the stream. They are not much esteemed for eating, but are readily and often shot in large numbers when congregated thickly on the mud-banks. In the north of Scotland the coot is only a summer bird, but in the south of England they stay all the year. The American Coot (*F. americana*) is common in all parts of North America.

Coote, SIR EYRE, soldier, born in County Limerick in 1726, entered the army at an early age, and from 1754 to 1762 served in India. It was by his arguments that Clive was induced to risk the battle of Plassey, and for his services in this and other engagements, Coote was in 1759 given the command of the newly-raised 84th regiment. In this year he gained the great victory of Wandiwash; and his capture of Pondicherry in 1761 completed the downfall of the French in India. Coote returned to England, and was knighted in 1771. In 1779 he assumed the command-in-chief in India, with the rank of lieutenant-general, and in 1781 he routed Hyder Ali at Porto Novo; his victory here, with the successes that followed, a second time saving the presidency. He died at Madras, 26th April 1783.

Cootchill, a town in County Cavan, Ireland, 88 miles NW. of Dublin. Pop. 1789.

Copaiba, or COPAIVA, BALSAM OF, a valuable drug, consisting chiefly of a resin (resin of copaiba) and a volatile oil (oil of copaiba). It flows from incisions in the stems of various species of *copaifera* trees, natives of the American tropics, which belong to the natural order Leguminosae. When these trees become old or surcharged with copaiba, it is no unusual thing for the stems to burst with a loud booming sound. The balsam has a peculiar, aromatic, but not disagreeable odour, which, however, is highly persistent, while its taste is decidedly acrid. It has stimulant properties, is diuretic, laxative, and in large doses often an active purgative. It is, however, mostly on account of its powerful action on the mucous membrane that it is used, and it is accordingly much employed in affections of the urino-genital system, in chronic catarrhs, &c. The resin itself has been found efficacious given in the form of a cough-pill. Balsam of copaiba is sometimes adulterated with castor-oil or volatile oils. The former of these is readily detected if any milkiness is produced when the balsam is shaken with ten times its volume of petroleum benzin. The volatile oils may be recognised by shaking the balsam with a little alcohol, when, being more soluble, they are removed first.

Copais, LAKE. See BÉOTIA.

Copal, a resinous substance used for a variety of purposes in the arts. It appears in commerce in smooth rounded masses, colourless or lemon-yellow, translucent or transparent, rather brittle, and in a cold state, almost without smell or taste. It is readily fusible and inflammable, is insoluble in water, and only partially soluble in alcohol and oil of turpentine, but becomes entirely soluble in them when it has been for a short time melted. Various useful pale-yellow or almost colourless varnishes and lacquers are made by dissolving melted copal in alcohol, oil of turpentine, or boiled linseed-oil. The chief sources of copal are the East Indies, Africa, and South America, but the varieties derived from these countries differ in their origin. The East Indian is the exudation of a large tree, *Valerica Indica*, and possibly also of different species of *Hymenaea*, which probably yield the Brazilian variety. Much copal is obtained from West Africa, where it is found in rounded masses, embedded in sandy soil. *Gum Animé* is the name applied to a copal of this nature.

Copalchi Bark, a bark resembling Cascarella Bark (q.v.) in its properties, and produced by a shrub of the same genus, *Croton nireus*, a native of Central America (see CROTON). The bark is in quills a foot or two in length, and has a thin corky epidermis. Copalchi Bark is much used as a substitute for cinchona in Mexico, where it goes by the name of *Quina blanca*, and is imported, although not to a large extent, into Europe. It contains a minute proportion of a bitter alkaloid resembling quinine.

Copan, an Indian village in the south-western corner of the Central American state of Honduras, in a mountainous region, the site of a city still populous at the time of the conquest, and of which magnificent ruins still remain, first described by Stephens.

Coparcenary, an estate in England originating in descent to two or more persons, called thence coparceners or parcenars. It generally arises under the rule of law which makes the daughters of one dying without male heirs inherit equally, but it may also arise by local custom, as in the case of Gavelkind (q.v.). Although the property remains undivided, yet each parcenar is entitled to a dis-

inct share of it, and consequently there is no benefit of survivorship as in joint-tenancy, but the right of each descends to his or her heirs. The rule of descent is also *per stirpes*, so that the heirs of one who has predeceased the common ancestor take only the share which would have come to their immediate ancestor had he or she survived, and thus in the rare case of gavelkind a grandson of the common ancestor will also exclude his own sisters. Division may be carried through by voluntary agreement, or by a suit in Chancery. Such parts of the property as cannot be divided (such as the manor-house, &c.) pass to the eldest sister or her issue, but an equivalent in value is assigned to the remaining sisters. These principles resemble closely the law of common property in Scotland, as to which the right of individual management extends only to necessary operations, not to extraordinary use of the subject. Each *pro indiviso* owner may sell his right, and, except in the case of conjunct rights to husband and wife (which are considered indivisible), may insist on an action of declarator and division. If the subject is naturally indivisible, as a brewery, it may be sold and the price divided. In the case of heirs-portioners in Scotland, also, such things as a peerage, a public office, or a mansion-house with accessories form a *præcipuum* for the eldest sister. Where the *præcipuum* comes under a settlement, compensation is generally due to the younger sisters. An Advowson (q.v.) is exercised in turns, according to seniority.

Co-partnery. See PARTNERSHIP.

Cope (Lat. *cappa*, *pluviale*), an ecclesiastical vestment worn in the Latin Church during processions, solemn lauds and vespers, and other

solemnities, but not by the celebrant at mass. The Greek form of the cope (*manudus*) is restricted to archimandrites and bishops. The cope of the former is plain, that of the latter with a pattern of wavy stripes. The Armenians alone use the cope as the vestment for mass. In the Church of England the cope was allowed as an alternative to the vestment or chasuble by the Common Prayer-book of 1549. Both were forbidden by that of 1552, but legally revived under Elizabeth in 1559. By Canon xxiv. of 1603, the principal minister at the Holy Communion in cathedral or collegiate churches, together with the epistoler and gospeller, is directed to wear the cope, and at Durham it was so worn till Bishop Trevor's episcopate (1752-71), when one of the prebendaries disused it, finding it interfered with his wig. The cope, however, has been customarily worn by the clergy officiating at coronations; while some further revival of its use has taken place of late years. The cope was originally a cloak worn for ordinary purposes. In form it is a semicircle, without sleeves and with a hood. It is fastened across the breast with a clasp or morse. Copes soon began to be ornamented with embroidery, and even with jewels; and so early as the 13th century they became the most magnificent and costly of all the vestments of the priesthood.

Cope.

revival of its use has taken place of late years. The cope was originally a cloak worn for ordinary purposes. In form it is a semicircle, without sleeves and with a hood. It is fastened across the breast with a clasp or morse. Copes soon began to be ornamented with embroidery, and even with jewels; and so early as the 13th century they became the most magnificent and costly of all the vestments of the priesthood.

Cope, CHARLES WEST, R.A., subject-painter, was born at Leeds in 1811, the son of a landscape-painter. He attended the schools of the Royal

Academy, and studied for two years in Italy. He began to exhibit in the Academy in 1833, and produced a long series of sacred, historical, and domestic subjects. In 1843 his cartoon, 'The First Trial by Jury,' gained a £300 prize at the Westminster Hall competition; and in 1844 he was selected to execute, in the House of Lords, a mural painting of 'The Black Prince,' which was followed by 'Prince Henry,' and in the Peers' Corridor a series of eight subjects from the Civil War, completed about 1865. He was elected an A.R.A. in 1843, and an R.A. in 1848; and from 1867 to 1874 he held the professorship of Painting. He retired in 1883. He was an original member of the Etching Club, and his plate of 'The Life Class of the Royal Academy' (1865) ranks as one of the most vigorous figure-subjects ever etched by an Englishman.

Cope, EDWARD DRINKER, American naturalist, born in Philadelphia, 28th July 1840, was professor of Natural Sciences at Haverford College, 1864-67, and afterwards appointed paleontologist to the United States Geological Survey. His numerous papers and works on paleontology are highly valued; and to the discussion of the theory of evolution he has contributed over a dozen works of importance. He is a member of numerous scientific societies in America and in Europe, and among other recognitions of his services to science, he, in 1879, received the Bigsby gold medal of the Royal Geological Society.

Cope, SIR JOHN, an English general, was a cornet in 1707, and, having been made a Knight of the Bath, in 1742 commanded the troops sent to the assistance of Maria Theresa. On the landing of Prince Charles Edward in 1745, Cope was appointed commander-in-chief of the government forces in Scotland. After a fruitless march to the Highlands, he returned with his troops by sea to Dunbar, and on 21st September was totally defeated at Prestonpans. His defeat is celebrated in the Jacobite song, 'Hey, Johnnie Cope, are ye waukin' yet?' Cope died 28th July 1760.

Copec. See KOPECK.

Copenhagen (Dan. *Kjøbenhavn*, 'Merchants' Haven'), the capital of Denmark, and headquarters of the national commerce, literature, and art, is situated on the low-lying eastern shore of the island of Zealand, in the Sound, which is here about 12 miles broad; an outlying portion, Christianshavn, stands at the north end of the island of Amager or Amak, which is separated from Zealand by a narrow arm of the sea. The channel forms a fine and capacious harbour, which is bridged over so as to connect Christianshavn and the main part of the city at two points. The fortifications on the land side have been removed since 1863; so that the city has now practically incorporated the suburbs Österbro, Nørrebro, Vesterbro, and Frederiksberg. The total population in 1735 was 60,000; in 1835, 120,000; in 1880, 235,254; and in 1885 it was, with suburbs, 285,700. Copenhagen is still defended by the old citadel of Frederikshavn and by forts on the seaward side; and in 1887 new fortifications were in course of construction. The business quarter stretches from its noble harbour in a north-east direction towards the principal and central square, Kongens Nytorv, which in itself forms the focus of the life of the city. Farther north and east of this point lies the aristocratic quarter, with the handsome Amalienborg Square and its royal and ministerial palaces; this district is bounded in the extreme north by the citadel, and the adjoining public gardens and walks on the shores of the Sound.

Amongst its few buildings of historical interest or intrinsic beauty, the metropolitan cathedral

church, known as Vor Frue Kirke, rebuilt after the bombardment of 1807, possesses statues of Christ and the Apostles, and a baptismal font, designed and in part executed by Thorwaldsen. Trinitatis-kirke is remarkable for its round tower, which is ascended by a winding causeway instead of steps; and Holmens' Kirke contains interesting monuments to the great naval heroes, Juel and Tordenskjöld. An English church, built at a cost of £10,000, was consecrated in 1887. The royal palace, called Christiansborg, was rebuilt between 1794 and 1828, but was never remarkable for architectural beauty. The principal part of the vast building was destroyed by fire in 1884, when many precious works of art were destroyed. Happily most of the pictures in its great art gallery were saved. The castle of Rosenborg (1610-24), where the regalia are kept, contains interesting collections of objects of art; and the palace of Charlottenborg (1624) is now used as an academy of arts. The university was founded by Christian I. in 1479, has five faculties, 40 professors, and is attended by 1200 students. Connected with the university are a surgical academy, an observatory, a botanical garden, a zoological museum, a polytechnic institution, and a library of 250,000 volumes, containing also a great collection of ancient Persian MSS., and another of ancient northern MSS. Copenhagen is the centre, not only of Danish, but of northern literature and art, and is the seat of a number of societies for the advancement of these in all their branches, amongst which the most important are the Royal Society, founded in 1742; and the Royal Society for Northern Antiquities, founded in 1825; as well as agricultural, geographical, and other societies. The royal library contains 500,000 volumes, besides great treasures of Sanskrit and other MSS. The Museum of Northern Antiquities in Prindsens Palais, is unrivalled in its kind, having been made what it is mainly by Worsaae. The Thorwaldsen Museum, opened in 1846, consists of works of art by that sculptor himself, and others left by him to the Danish nation, for which a separate building has been erected. Copenhagen contains also a number of well-supported benevolent institutions, banks, theatres, an exchange, &c. There are statues of several of the Danish kings, of Tycho Brahé, and of the poets. The chief exports of Copenhagen are grain, rape-seed, butter, cheese, beef, cattle, wool, hides, bones, and grain-spirit. Porcelain, pianos, clocks, watches, mathematical instruments, chemicals, sugar, beer, and tobacco are manufactured.

About the middle of the 12th century, Copenhagen was but a fishing-village, in the neighbourhood of which Bishop Axel, or Absalon, built a castle. In 1254 the village obtained the privileges of a town, and in 1443 King Christopher made it the capital of the kingdom. It was several times attacked by the Hanseatic League; was besieged by the Swedes in the 17th century; was bombarded by the English, Dutch, and Swedes in 1700; suffered grievously by fires in 1728, 1794, and 1795; witnessed a great sea-fight in its roads on 2d April 1801, when the English, under Sir Hyde Parker, with Nelson as his second in command, destroyed the Danish fleet; and (to prevent the Danish fleet from falling into the power of Napoleon) was bombarded by the English from the 2d to the 5th of September 1807, when great destruction was wrought, both in houses and public buildings, and hundreds of persons lost their lives (see DENMARK). In 1888 an international exhibition was held here.

Copenhagen Fields, in North London, noted as the meeting-place of an immense gathering of labour unionists on 21st April 1834, with the object

of overawing the ministry. But the crowd, seeing the military and other preparations made to receive them, dispersed quietly without attempting to carry out any of the violent designs with which they were credited. Since 1885 the site has been occupied by the Metropolitan Cattle Market.

Cope'poda, an order of minute marine and fresh-water crustaceans, belonging to the Entomostraca (q.v.).

Coper'nicus, NICOLAS, founder of the modern astronomy, was born 19th February 1473, at Thorn, in West Prussia, lately belonging to the order of the Teutonic Knights (q.v.), but then a part of Poland. His father, a Polish subject, was apparently a Germanised Slav, and his mother of pure German extraction. Copernicus seems to have spoken German as his mother-tongue; but Poland and Germany still dispute with each other the honour of producing him. Brought up under the guardianship of his uncle Lucas, prince-bishop of the great Prussian diocese of Ermland, he matriculated at Cracow 1491, and there studied mathematics, optics, and perspective. Leaving without taking a degree, he enrolled himself in 1496 in the 'Natio-Germanorum' of Bologna University as a student of canon law, and was next year appointed canon of Frauenburg, the cathedral city of the diocese of Ermland, standing on the shores of the Frisches Haff. The year 1500 he spent at Rome, where he lectured on astronomy, and (6th November) 'observed an eclipse of the moon.' The following year he began the study of medicine at Padua, medicine in that age being essentially dependent on astronomy, and was at Ferrara, in 1503, invested with the doctorship of canon law. In 1505 he left Italy never to return to it, and settled in his native Prussia. 'Scholasticus' of Breslau till 1538, and canon of Frauenburg, yet Copernicus never became a priest. Appointed permanent medical attendant on his uncle, he lived with him from 1507 till 1512 in the princely castle of Heilsberg, 46 miles from the town of Frauenburg, where, besides thinking out his new astronomy, he had toilsome administrative and other duties to perform, involving him in frequent journeys. After his uncle's death in 1512, he lived at Frauenburg with an income as canon calculated at about £450 of present money, not merely to study the stars in his tower *Curia Copernicana*, but to execute difficult and multifarious offices as bailiff, military governor, judge, tax-collector, vicar-general, and physician. These offices he fulfilled with vigour and success, even while his difficulties were increased by the intrigues and wars which ultimately led to the restoration of West Prussia to the Teutonic Knights, and its incorporation with the Protestant state of Brandenburg. The coinage having been grossly debased by the Teutonic Knights and the three leading commercial towns of Prussia, Copernicus set himself strenuously to the task of its reform, and advocated the establishment of a single mint for the whole of Prussia. In 1523 he was appointed administrator-general of the diocese. The *De Revolutionibus* he completed in 1530, but could not be prevailed on to give it to the press till just before the end of his life. In 1542 he was seized with apoplexy, accompanied by paralysis on the right side. On the 24th May 1543 the first printed copy of the work arrived at Frauenburg, and was touched by his dying hands only a few hours before he expired. His memory gone, and his faculties all obscured, it could only be said he seemed to know what it was he touched.

Besides the *De Revolutionibus*, Copernicus wrote and published at Cracow a Latin translation of the Epistles of the Byzantine author Theophilactus Simocatta, and a treatise on trigonometry. His

life was written by Gassendi; more recently by Von Hipler (1873), and Polkovski (Warsaw, 1873). By far the most complete account of Copernicus's life and labours is, however, the great biography by Dr Prowe (2 vols. Berlin, 1883; volume of documents, 1884). Copernicus's family name of *Koppernigh* is derived from a village so called in Silesia, and was Latinised by himself as *Copernicus*, and indeed by him generally so spelt.

THE COPERNICAN SYSTEM is that which represents the sun to be at rest in the centre of the universe, and the earth and planets to move round it as a centre. It got its name from Copernicus, who (although some vague general notion of the system seems to be due to Pythagoras) first distinctly drew the attention of philosophers to it, and devoted his life to its demonstration. For the rest, the glory of developing on the lines he broadly laid down, belongs to Kepler, Galileo, and others, and to Newton, who finally marked out the form of modern theoretical astronomy. Many who reverence the name of Copernicus in connection with this system, would be surprised to find, on perusing his work, how much of error, unsound reasoning, and happy conjecture combined to secure for him in all times the association of the system with his name; yet, with all its faults, that work marks one of the greatest steps ever taken in science.

Entitled *De Revolutionibus Orbium*, and dedicated to Pope Paul III., it consists of six books. The first contains the following propositions: 1. That the universe is spherical. This is established by such arguments as that the sphere is the most perfect figure, &c. 2. That the earth is spherical, which flows from the same kind of considerations. 3. That the earth and sea make one globe. 4. That the motions of all the heavenly bodies must be uniform and circular, or compounded of uniform and circular motions. Here, again, we meet with singular reasons. A *simple* body must move circularly, and nothing but circular motion could give periodicity to phenomena. 5. That, supposing the distance of the stars to be immense, there is no reason why the earth should not have a motion round its axis as well as a motion in its orbit. 6. That the sphere of the stars is immensely distant. The proof is fanciful, and shows he had no notion of a universe of stars pervading space. 7 and 8. The ancients were wrong in placing the earth at the centre of the universe. The arguments under this head are as fanciful as those which they were designed to refute. The falling of a body to the earth he deduces from the assumption, that it is only given to wholes to move circularly, while it is of the nature of parts, separated from their wholes, to move in right lines. That there must be a *centrum mundi*, an entity unknown to modern science, is admitted, the question being as to its position. 9. It is possible for the earth to have several motions. 10. He establishes the order of the planets, and draws a diagram of the system much as it is now represented. Following the old systems, such as the Ptolemaic, he lays down a *sphere* for the fixed stars. It is clear, also, that he had no idea of the motions of the planets other than that they were such as would be caused by their being fixed in immense crystal spheres revolving round the sun.

The sum of Copernicus's astronomical achievements is, mainly, the shifting of the centre of the solar system from the earth to the sun, and the consequent explanation of the alternation of day and night by the earth's rotation round itself, and of the vicissitude of the seasons by the earth's revolution round the sun. This complete transformation in astronomy was due in the first

instance to the sense of order in Copernicus's own mind, which, ever more clearly, protested against the inverse conception of a much smaller body at the centre, and a far greater at the circumference, and all the repugnant notions regarding the movements of the planets which such a conception involved. Discriminating motion as an attribute of matter, and space as the scene but not the subject of motion, Copernicus explained how the celestial sphere was but a limitation of space, and its movement only apparent; and how the 'backward loopings' of the paths pursued by the planets were only the perspective result of their real movements in conjunction with the real movements of the earth. Such was the comprehensive scheme of astronomy conceived by Copernicus; but it was impossible for him, with the instruments and ascertained facts then at his disposal, to master all the details. Instead of grasping the idea of elliptic orbits, he still abode by that of uniform circular motion, and had therefore to retain the 'epicycles' to account for 'irregularities,' though he reduced this apparatus of checks and balances to the number of thirty-four. It was reserved for Kepler to dispense with the epicycles (see PROLEMAIC SYSTEM, ASTRONOMY, KEPLER). Catholic churchmen received Copernicus's work with much favour; the only theological objections came from the Protestants. Luther denounced Copernicus as an arrogant fool who wrote in defiance of Scripture, and Melancthon urged the suppression of such mischievous doctrines by the secular power. The conduct of the *De Revolutionibus* through the press having been delegated by Copernicus's friend, George Joachim von Lauchen (Rheticus) to Osiander (q.v.), the latter, by way of conciliating existing prejudices, foisted on the work a preface (*Prefatiuncula*) quite foreign from Copernicus's intentions, in which the doctrine of the earth's rotation is represented as a mere hypothesis, which has been attributed wrongly to Copernicus himself.

Coplapo, capital of the Chilian department of Atacama (q.v.).

Copland, JAMES, physician, was born at Deerness, in the Orkneys, in 1791. He graduated M.D. at Edinburgh in 1815, and settled to practice in London in 1820, where he soon began to make his name known by his papers in the medical journals on yellow-fever, hydrophobia, cholera, and the like. His largest work was the *Dictionary of Practical Medicine* (3 vols. 1832), a monument of enormous industry; others were on palsy and apoplexy (1850), and on consumption (1861). He died 12th July 1870.

Copley, JOHN SINGLETON, R.A., portrait and historical painter, was born 3d July 1737, at Boston, U.S. His parents, both of English extraction, had emigrated from Ireland in the previous year. It has usually been asserted that Copley was a self-taught artist; but Mr W. H. Whitmore of Boston has shown that he was instructed by his stepfather, Peter Pelham, the portrait-painter and engraver, and probably also by John Smibert. At the age of sixteen he was executing portraits of considerable merit; and in 1755 Washington sat to him. In 1766 and 1767 he sent over works for exhibition in the rooms of the Society of Incorporated Artists; and in June 1774 he left for Europe. In London he was well received by Reynolds, West, and Strange, and he was commissioned to paint the king and queen for General Wentworth. Passing to the Continent in August, he studied in Italy, returning to London in the end of 1776. His first important subject-picture was the 'Youth rescued from a Shark,' presented by the artist to Christ's Hospital School; which was followed by 'The

Death of Chatham' (1779-80), an impressive subject, in which the portraits of the peers were carefully studied from life, and the still finer 'Death of Major Pierson' (1783). Both are in the National Gallery; the former was engraved by Bartolozzi, the latter by Heath. In 1789-90 he executed the immense 'Siege and Relief of Gibraltar,' now in the Guildhall. Among his numerous other popular works may be named 'The Surrender of Admiral de Windt to Lord Duncan,' 'Charles I. demanding the Surrender of the Five Members,' now in Boston; 'Charles I. signing Strafford's Death-warrant,' and 'The Assassination of Buckingham.' Till the end of his life he was unwearied in the pursuit of his art. In August 1815 he was attacked by paralysis, and died on 9th September, leaving a son, the future Lord Lyndhurst.

Copley's historical subjects are more original, spirited, and realistic than those of his friend and countryman West, with whom he is commonly classed; and they are distinguished by far richer and finer colouring. His composition is simple and effective, and his draftsmanship careful and accurate. In religious and poetical subjects he was less successful. His portraits, full of individuality, excellent in modelling and colour, are in themselves enough to justify a great reputation; and in artistic qualities the finest of them may be said to approach the works of Reynolds and Gainsborough. See Lives by Perkins (1873) and Mrs Amory (1882).

Copper. This appears to have been the first metal employed by man both in war and the peaceful arts. Like gold and silver, it is found native, but, except in one or two districts, only to a small extent. It can, however, be extracted from its ores at a comparatively low heat, and it is not altered by exposure to dry air; although in moist air, in the presence of carbonic acid, it soon takes on a coating of the green carbonate of copper. The use of copper by ancient nations is well known, through the weapons and other objects of Bronze (q.v.)—that is, copper mixed with a small quantity of tin, &c.—which have been so largely collected by archaeologists. Some prehistoric implements are, however, of unalloyed copper. It was obtained by the ancients from various places, but especially from Cyprus—whence the name. Copper has a characteristic fine red colour and takes a brilliant polish. It is nearly nine times heavier than water, its specific gravity being from 8.8 to 8.95. Next to silver it is the best conductor of heat and electricity, hence its many useful applications. Its point of fusion lies between silver and gold, but unlike these metals, it absorbs oxygen when strongly heated in the air, and scales of black oxide form rapidly on its surface. Copper is moderately hard, and is highly malleable, ductile, and tenacious, although not so strong as iron. When held, in the form of sheet or wire, in a flame, it communicates to it a highly characteristic green colour. Whereas steel is hardened by being heated to redness and suddenly cooled in cold water, copper is softened by the same process. Copper forms two important compounds with oxygen—cuprous and cupric oxides.

Cuprous Oxide (red oxide, sub-oxide), Cu_2O . This is obtained by heating to redness the black oxide with nearly its own weight of finely divided copper in a well-covered crucible, to protect the mixture from the oxidising action of the air. It is got as a hydroxide by adding grape-sugar to a solution of sulphate of copper, and then caustic soda, till a blue precipitate, which is first formed, is redissolved. The solution, on being gently warmed, deposits the hydroxide as a rich orange-yellow powder. On continuing the heating till the liquid has reached the boiling-point, and maintaining the ebullition for some time, the powder changes into

the red anhydrous oxide. This oxide is used in colouring glass a fine ruby tint. It is not acted on by air or moisture, and for this reason is produced on copper surfaces as a bronze to keep the metal itself from becoming stained. The salts of this oxide are generally colourless, but they are liable to absorb oxygen and pass into the blue-coloured cupric salts. Cuprous chloride is the most important salt, being used for absorbing carbonic oxide in gas analysis.

Cupric Oxide (copper monoxide, black oxide), CuO , is the scale or rust of copper which peels off the surface of the metal when heated. It is got for chemical purposes by heating nitrate of copper to redness in a crucible with occasional stirring, and carefully avoiding any possible admission of coaly matter. By the use of cupric oxide Liebig established the method by which the composition of all organic substances has been determined, as it readily gives up its oxygen at a red heat to carbon and hydrogen, converting them, respectively, into carbonic acid and water, from the weight of which the composition of the organic body is calculated. This oxide is used for staining glass, to which it imparts a green colour; and its solution in ammonia has the remarkable property of dissolving cotton fibre. The *Hydroxide*, $\text{Cu}(\text{OH})_2$, is obtained as a blue precipitate by adding caustic soda to sulphate, or other salt, of copper, which, as in the case of the cuprous oxide, becomes anhydrous on boiling, the blue precipitate becoming black and granular. The salts of cupric oxide are readily obtained by dissolving it in the necessary acids; for example, in sulphuric acid for the sulphate, and in nitric acid for the nitrate of copper.

Cupric Sulphate (sulphate of copper, blue vitriol), CuSO_4 , occurs native in veins of copper and iron pyrites, and is manufactured on a large scale by gently roasting native copper sulphide (copper pyrites), when oxygen is absorbed from the air, the anhydrous sulphate thus obtained being dissolved in water, and from this solution the salt as found in commerce crystallises out. The crystals are large, transparent, and have a fine blue colour. They are much used by the dyer and calico-printer, in electroplating, and in the preservation of organic materials.

Cupric Nitrate, $\text{Cu}(\text{NO}_3)_2$. The crystals of this salt are of an intense blue colour and deliquescent. It is much used in calico-printing as an oxidising agent.

Cupric Cyanide, CuCy_2 , along with cyanide of potassium, gives the solution from which copper is deposited on an iron surface. It is not, however, necessary to prepare pure cupric cyanide, as the sulphate in excess of potassium cyanide serves the purpose.

Cupric Arsenite, CuHAsO_3 (Scheele's green), is a well-known green pigment, got by adding an alkaline arsenite to cupric sulphate, and washing the precipitate till free from sulphate, and drying. This colour has been much used for wall-papers, but has been supposed to have insanitary effects. See ARSENIC.

Copper Acetate, $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2$, is got by adding copper hydroxide, or carbonate, to acetic acid. It forms dark blue prisms. If acetic acid is allowed to act on metallic copper in the presence of air and moisture, a basic acetate is slowly formed termed *verdigris*; this has less acetic acid than the previous compound, and is much less soluble. It has a bluish-green colour. Verdigris and arsenious acid boiled together in water form the fine colour termed *emerald green*—an aceto-arsenite of copper.

Copper Stearate is obtained by adding stearate of soda to sulphate of copper in hot solutions. It is a light bluish-green powder used for colouring candles.

The pigment, *Brunswick green*, used in the arts, is an oxychloride of copper.

Copper in any liquid is easily discovered by placing in it a plate of polished iron, when it will be observed coating the metal with its well-known reddish tint, making its appearance over the part of the plate immersed in the fluid. If the quantity of copper is very small, the liquid should be concentrated till it half fills a watch-glass, and a bright steel needle used in place of an iron plate. Solutions of cupric salts have a blue or greenish-blue colour, but this on addition of ammonia in excess becomes an intense purplish blue.

Native Copper, although frequently met with wherever copper ores occur, is yet rarely discovered in sufficient quantity to admit of its being systematically worked. It is found crystallised in cubes and in modifications of this form; also in arborescent pieces, in thin laminae, and in irregular lumps or masses. Sometimes it forms a nucleus with first a layer of red oxide and then a second layer of carbonate of copper around it. The largest masses of native copper are obtained from mines in Russia and from copper-bearing strata in the neighbourhood of Lake Superior. One mass was mined at Minnesota in 1859, weighing 500 tons, which required the work of forty men for a year to extract it. The largest yet obtained was got in 1866 at the Central mines, Lake Superior, and weighed 800 tons.

The ores of copper are numerous. *Cuprite*, *ruby copper*, *cuprous oxide*, or *red oxide of copper*, is the richest ore. It contains, when pure, nearly 90 per cent. of copper. *Malachite* (q.v.), or *green carbonate of copper*, consists, when pure, of 57 per cent. of the metal. This ore occurs largely in Russia, South Australia, and in some localities in South America. *Chrysotile*, *azurite*, or *blue carbonate of copper*, in a pure state contains 55 per cent. of copper. *Chalcoprite*, *copper pyrites*, or *yellow copper ore*, a sulphide of copper and iron, is, from its abundance, the most important of copper ores. Although containing, when pure, 35 per cent. of copper, yet on account of impurities, what is mined in England does not yield, on an average, more than 8 per cent. of the metal. Some of the auriferous copper pyrites of the western states of America and elsewhere is worked as an ore of gold (see GOLD). *Erubescite*, or *purple copper ore*, is also a sulphide of copper in which the proportion of the metal varies from 60 to 70 per cent. *Tetrahedrite*, or *gray copper ore*, is a sulph-antimonite of copper of very variable composition, but often containing from 30 to 40 per cent. of copper, &c. *Atacamite* (q.v.) is an oxychloride of copper mined in Chili, and found in other countries. *Melaconite*, or *black oxide of copper*, and *Chrysocolta*, a silicate of copper, are sometimes smelted as ores of the metal.

COPPER-SMELTING.—In practice, the process of smelting copper from ore (copper pyrites) like the Cornish is somewhat complicated, but in theory it is comparatively simple. The main impurities of the ore are quartz, iron, sulphur, and very commonly arsenic. The process is conducted with the view of separating the iron and quartz as a fusible slag, and of dissipating the sulphur and arsenic, by converting them into sulphurous and arsenious acids, through oxidation in the furnace. At Swansea, which is the chief seat of copper-smelting in this country, reverberatory furnaces are used, and these are of two kinds, called respectively calciners and melting furnaces. Gas, along with Siemens' regenerative apparatus, is now to some extent used in different parts of the world for supplying heat to copper furnaces, but at some places it has been given up, after a short trial, owing to the costly repairs which it causes. There are never fewer than six operations in the Welsh process of copper-smelting, and when so limited, a favourable

admixture of ores, such as copper pyrites and copper carbonates, is necessary. In the *first*, the ore is calcined in a furnace for at least twelve hours, by which time the greater part of the sulphide of iron is decomposed, and much sulphurous and other acids have formed and escaped in fumes—i.e. a partial oxidation of the iron and sulphur

Fig. 1.—Section of a Reverberatory Copper-melting Furnace:

A, fireplace; B, fire-bridge; C, bed of sand; D, melted copper.

takes place. In the *second*, the calcined ore is melted along with siliceous slags obtained in later stages of the process. Here a fusible slag, consisting in great part of silicate of iron, is formed, and the sulphides of iron and copper are run off as a regulus, termed *coarse metal*, and granulated in water. A section of a melting furnace is given in fig. 1. In the *third*, the coarse metal is calcined again for twenty-four hours, during which time most of the sulphide of iron is converted into oxide. In the *fourth*, the calcined coarse metal is melted with slags rich in oxide of copper, and also with rich ores, as oxide and carbonate. These oxidise any sulphide of iron remaining, and a regulus called *white metal* is formed, consisting almost entirely of sulphide of copper, and containing about 75 per cent. of the metal. In the *fifth*, called 'roasting,' the regulus is very slowly melted, so as to allow of the gradual and thorough reduction of the sulphide by heated atmospheric air through the formation of oxide of copper. When oxide and sulphide of copper are heated together, they decompose each other, the sulphur escapes as sulphurous acid, and impure metallic copper, called *blister copper*, is produced, while other foreign bodies are for the most part removed in the slag. In the *sixth*, the copper from the previous operation is refined. To effect this, it is melted in a furnace, and exposed to the oxidising influence of the air for from fifteen to twenty hours, by which time it is full of dioxide, and this is in turn reduced by throwing pure coal on the surface of the molten metal, and then stirring it with a pole of green birch-wood.

At those smelting works where the sulphurous acid produced in the calcining or roasting of copper pyrites is saved for the manufacture of sulphuric acid, peculiar furnaces, such as Gerstenhöfer's, Hasenclever and Helbig's, and Maletta's, are used for roasting the ore. Shaft or cupola furnaces, instead of those of a reverberatory kind, are used in some countries, for smelting copper ores where these are highly ferruginous, or oxidised, or comparatively poor. Coke, anthracite, or charcoal is used as fuel in cupola furnaces, which require a blast of air at a moderate pressure.

Wet Copper Extraction Process.—Soon after iron pyrites (sulphide of iron) began to be used about thirty years ago as the source of sulphur for the manufacture of sulphuric acid, it was thought desirable to recover the copper, amounting to a small per cent. of the pyrites used. The burnt pyrites, consisting chiefly of oxide of iron, along

with 4 or 5 per cent. of copper, is mixed with from 12 to 15 per cent. of crushed rock-salt and the mixture properly calcined, when the whole of the copper is converted into a soluble chloride. The roasted mass is then lixiviated, and the copper contained in the solution thrown down as metal by scrap iron. This precipitate contains about 75 per cent. of pure copper, and is mixed with the copper of the later stages of purification got in the dry process.

APPLICATIONS OF COPPER.—The metal is used for a great variety of purposes. It is most largely consumed along with zinc in the production of Brass (q.v.). To a less, but still considerable extent, it is made into bronze and gun-metal, in which it is alloyed with tin and other metals (see BRONZE). Alone it is employed for boilers, stills, cooking vessels, seamless and other pipes, wire and wire-cloth, nails, and spikes. In the form of thin plates it has long been in demand for engraving and etching upon, and in the shape of strong rollers it is extensively employed for a like purpose by the calico-printer. Copper does not cast very well, but it is admirably adapted for producing works of art in electro-deposit instead of casting them. This process is extensively employed, and does even for objects as large as life-sized statues. In this way engravings and pages of type are also copied for the printing-press. For its use in coating other metals, see BRONZING. Copper is the metal usually chosen for lightning conductors. Writing-pens are made of an alloy consisting for the most part of copper, and for some purposes are better than those made of steel, as they do not corrode nearly so soon. These pens are usually white in colour. An alloy of copper, 'yellow metal,' is used for sheathing the bottoms of timber ships, so as to prevent molluscs and seaweeds from encumbering them. Copper, owing to its ductility, may be made into pipes, tubing, &c., by high pressure alone, without heat.

The copper-mines of the United Kingdom appear to have first risen into importance in the early part of the 18th century. According to Sir C. Lemon (*Journal of the Statistical Society*, vol. i.), the produce of the Cornish mines in 1771 was 27,896 tons of ore, yielding 3347 tons of copper. In 1856 (Hunt's *Mineral Statistics for 1856*) the returns were—Cornwall, 163,245; Devon, 42,025 tons of ore; together yielding 13,500 tons of metallic copper. Since 1860, the year of their maximum yield, the quantity of copper obtained from mines of the United Kingdom has steadily and rapidly declined from 236,696 tons of ore, and 15,968 of metal, to 18,205 and 1386 tons respectively in 1886.

The copper ore mined in other parts of the country besides Cornwall and Devon is comparatively trifling. Copper is chiefly smelted at Swansea and its neighbourhood, but to some extent also in Lancashire. The English smelting works are now most largely supplied with ore from Spain, South Africa (see CAPE COLONY, Vol. II. p. 735), Venezuela, the United States, and Australia (q.v.). The entire quantity of metallic copper smelted and refined in the United Kingdom in 1887 was 57,503 tons.

The production of copper in the United States has increased rapidly since 1872. In that year the quantity of this metal obtained was 12,500 tons, while in 1885 it was as much as 76,000 tons, and the United States is now the largest producer of copper. The richest mine in the world is said to be that at Calumet (q.v.), on Lake Superior, in which region copper was mined by the ancient Indian or pre-Indian inhabitants. The territories of Arizona and Montana are also productive; but copper occurs in several other parts of the Union. A very large quantity of copper wire is used in

that country for electrical purposes. The enormous increase in the output of copper between 1880 and 1884, and its fall in price, led to the formation of a powerful syndicate to regulate the total production and control the price; which till 1889 had largely succeeded in its aims.

Copperas is the commercial term for the sulphate of iron, and is used extensively in dyeing black, in making ink, and has been found useful as a dressing for crops. See IRON.

Copperhead (*Trigonocephalus contortrix*), a venomous serpent, closely allied to the rattlesnake, found in eastern North America, from New England to Florida. It has a thick body from 2 to 3 feet long, with a short tail without rattles, and is slow and clumsy in its movements; but, lurking in dark and moist places, and giving no warning of its proximity, it is more dreaded than the rattlesnake. The term was applied by the Federals to the peace party during the American civil war, as suggesting insidious foes.

Coppermine River, so named, in common with the Copper Mountains to the west of it, from the metallic products of the vicinity, runs through the North-west Territory of Canada, and after a course of 250 miles, enters a bay of the Arctic Ocean about 68° N. lat., and 116° W. long. It was discovered by Hearne in 1771. Its course is continually interrupted by falls and torrents.

Copperplate Printing. See ENGRAVING.

Coppet, a village of Switzerland, 8 miles N. by E. of Geneva by rail, with a château, where Necker and his daughter, Mme. de Staël, are buried, and where the latter spent much of her life.

Coppice. See COPSE.

Copra, or COPPERAH, is the commercial name for the kernel of the cocoa-nut broken into small pieces and dried in the sun. From 500 lb. of copra 25 gallons of cocoa-nut oil should be obtained. See COCOA-NUT.

Coprolites (from Gr. *kopros*, 'dung,' and *lithos*, 'a stone') are the fossilised excrements of animals found in Palæozoic, Mesozoic, and Tertiary strata. Their true nature was first inferred by Dean Buckland (1829), from their occurrence in the bodies of several species of Ichthyosaurus, in the region where was situated the intestinal tube. It has been since shown that they are the voidings chiefly of saurians and of sauroid fishes. They often contain portions of scales, bone, teeth, and shells, the indigestible parts of the food on which the animals lived. Occasionally, they may be found exhibiting the spiral twisting and other marks produced by the conformation of the intestinal tube, similar to what is noticed in the excrement of some living fishes. These peculiar markings obtained for them the name, when their true nature was unknown, of 'larch-cones' and 'bezoar-stones.' Coprolites are found to contain a large quantity of phosphate of lime; and as this forms a valuable manure, the deposits containing them have since 1846 been largely quarried by the manufacturers of artificial manures.

Copse, or COPPICE, a natural wood or plantation, of which the trees are cut over from time to time, without being allowed to attain the size of timber-trees, sending up new shoots from their roots or stools. Some kinds of trees—as the firs—are incapable of being treated in this manner, refusing to send up new shoots; but many—as the oak, birch, chestnut, ash, elm, maple, alder, hazel, and willow—very readily do so, at least if they have not been allowed to attain too considerable a size before being cut over. Copse-woods are sometimes planted chiefly to vary and beautify the landscape, but more generally with a view to profit.

It often happens that, owing to scantiness of soil or to unfavourable subsoil, oaks and other trees, after growing vigorously for a number of years, are arrested, and remain almost stationary in their growth. In such circumstances, it is advantageous to cut them over early, and to treat the plantation as a copse. Oak is much planted as copse-wood, in consequence of the demand for its bark: in some parts of Herefordshire, the trees are cut over every twelve years; but in the Highlands of Scotland, twenty-five or thirty years are often necessary for sufficient growth. The largest pieces of the wood are used for making wheel-spokes, and for other purposes of timber; the smaller portions for charcoal and firewood. Ash-coppice is serviceable for handles of implements, hurdles, hoops. Chestnut coppices are planted in England to supply hop-poles. Hazel is in great demand for making crates, &c. Besides the cultivation of different kinds of willow or osier for basket-making, in which they are cut over annually, some of the species are cultivated as copse, and cut every five, six, or seven years, for hoops, crates, &c. (see *WILLOW*). In some countries, copse-wood affords a valuable supply of fuel.

Coptis, a genus of *Ranunculaceæ*. *C. trifoliata*, called Gold Thread on account of the appearance and colour of its rhizomes, is a native of swamps in the colder northern regions of both hemispheres. It has ternate leaves and solitary white flowers. The bitter rhizomes are used in America as a tonic, and as a yellow dye. That of *C. teeta* of Assam is used in India as a bitter tonic.

Copts, the Christian descendants of the ancient Egyptians. The name (in Arabic, *Kubt*) is most probably derived from the same root as *Egypt*. The Copts are in number about 300,000, only one-eighteenth of the population of the country. A large proportion live in Cairo, but there are numerous populous settlements of Copts in Upper Egypt, notably at Girga, Negâda, Luksor, Asyût, Dendera, and Ikhmim, where 40,000 are said to reside. They are essentially townsmen, engaged as clerks on account of their undoubted mathematical talents; or employed in the finer handicrafts, such as goldsmithery; and their occupations account for their paleness as compared with their Moslem neighbours. The few Copts who work in the fields do not differ perceptibly from the Moslems, and the resemblance to the ancient Egyptians is visible in both, though the inbreeding of the Copt has perhaps retained the ancestral lineaments more faithfully. They are of middle stature, have black eyes, and black curly hair; dress like the Moslems, but are generally distinguished by a black or blue turban; the women are veiled. Their character is in general gloomy, deceitful, and avaricious; they are ignorant, drunken, and sensual. In religion they are Monophysites (q.v.) of the Jacobite sect; but a few are united to the Greek and Roman Catholic churches. When the Council of Chalcedon in 451 pronounced the Jacobite opinion heretical, some of the Copts supported the verdict, and bitter jealousies ensued between these 'royalists' and the Jacobite Copts. The latter did not scruple to welcome the Moslem conquest in 640 in order to expel the Greek faction. They ascribe their conversion from heathenism to St Mark, whom they regard as the first patriarch of Alexandria. Their highest dignity is the patriarch of Alexandria, whose residence, however, is in Cairo. Their other orders of clergy are twelve bishops, and archpriests, priests, deacons, and monks. The patriarch is named by his predecessor, or chosen by lot from among the monks of the convent of St Anthony. He is not permitted to marry, and when he sleeps it is necessary to waken him every quarter of an

hour. He nominates the metropolitan of Abyssinia (see *ABYSSINIA*).

The Copts are very strict in some of their religious observances, and hate other Christian sects even more than they hate the Moslems. They maintain the seven sacraments—baptism by trine immersion; confirmation; penance or confession; orders; matrimony; unction; and the eucharist, administered in both kinds to all, even young children, and formed of leavened bread which has been dipped in wine. They keep Wednesday and Friday with great strictness as fast-days, and have besides an onerous fast of Nineveh, lasting fifty-five days, and lesser fasts of the Nativity, the Apostles, and the Virgin. Each fast is followed by a feast. Pilgrimage to Jerusalem is prized highly. Priests may be married to one virgin provided the ceremony takes place before ordination; if the wife die, he may not marry again, nor may the widow of a priest remarry. The Copts seldom marry outside their own sect; the wedding ceremonies are very peculiar, and may be read in L. Oliphant's *Land of Khemi*; the bride is expected to remain at home until confined, or for a year if barren (see Lane's *Modern Egyptians*). The Coptic ritual, liturgy, vestments, &c. are specially interesting as preserving unchanged very ancient Christian forms. The churches, of which the most celebrated are those built in the Roman fortress of Babylon at old Cairo, and those in the Nitrian valley, are remarkable for peculiarities of construction and plan, and for exceedingly beautiful carved ivory screens. An admirable account of them is given by Mr Butler. They have many schools, but only for boys, who learn the psalms, gospels, and apostolic epistles in Arabic, and then the gospels and epistles in Coptic. The Coptic, however, is not grammatically taught, and is not now a spoken language, having been everywhere supplanted by the Arabic. It has not been spoken in Lower Egypt since the 10th century, but lingered for some centuries longer in Upper Egypt. It is, however, still used by the Copts in their religious services, but the lessons, after being read in Coptic, are explained in Arabic. The Coptic language is the descendant of the ancient Egyptian, but the alphabet is Greek uncial, probably introduced soon after their conversion to Christianity. 'The romance of language could go no further than to join the speech of Pharaoh and the writing of Homer in the service-book of an Egyptian Christian' (Butler). There are two principal dialects of the language—the Sahidic or Upper Egyptian, and the Memphitic or Lower Egyptian, which is sometimes exclusively called Coptic. A third dialect, the Bashmuric, of which only a few remains exist, was spoken in the Delta, and is interesting from its points of resemblance to the language of the hieroglyphics. The literature is wholly religious. See the article *EGYPT*; and *The Ancient Coptic Churches of Egypt*, by Alfred J. Butler (2 vols. Oxford Clarendon Press, 1884).

Copula (Lat., 'a band') is a term employed in logic to designate the word which unites the two notions of a sentence—the subject and predicate—into one judgment or thought.

Copyhold, a species of estate or right of property in land, in Ireland and England, nearly resembling in many particulars the feu-rights of Scotland. Copyhold is expressed technically as 'tenure by copy of court-roll, at the will of the lord, according to the custom of the manor.' This means that it is tenure of land, being part of a manor, the title being evidenced by the court-rolls of the manor, and the right of the owner being in conformity with the immemorial customs of the manor. The addition, 'at the will of the lord,'

serves only as a memorial of the derivation of this species of estate from the estates granted in old times to the bondsmen or *Villeins* (q.v.), which were of course resumable at the pleasure of the lord. But the will of the lord is now absolutely controlled by the custom of the manor, which forms the law of the tenure; and as this custom must be immemorial—i.e. extending to the reign of Richard II.—no copyhold can now be created.

The custom of each manor may vary in important particulars. In some the lands are held for life only; generally, however, with a customary right to renewal or to appoint the successor; in some they descend according to particular rules; in most, however, they descend according to the ordinary rules of succession. But the custom, whatever it may be, cannot be altered. The tenant cannot, for instance, entail his land unless the custom warrants him. The freehold remaining in the lord includes a right to minerals and timber, but in the absence of special custom he cannot remove these without the consent of the tenant. The tenant also in the general case cannot lease his land for more than one year. This tenure makes the intervention of the lord necessary in every act of alienation, which therefore resembles the Scottish procedure of resignation of a feu, and is called a surrender and admittance.

Various money-payments are due by the copyholder to the lord. These are divided into the *rents*, an annual payment of the nature of the Scottish feu-duty; *fines*, payments on particular occasions, such as alienation or succession, like the Scottish composition to the inferior; and *heriots*, or the best piece of personal property, to which, on the death of the copyholder, the lord becomes entitled. As to fines, it may be observed that the courts of law have fixed the extreme amount that can be exacted at two years' rent of the land.

In the case of an heir succeeding there is no surrender, but there is admittance only upon payment of the customary fine, and it is enforced by a customary penalty. A mortgage is effected by a surrender, upon condition that the money is repaid, and the admittance takes place only in event of failure of payment. A copyhold may, in like manner, be devised by will, the devisee being admitted on the death of the deviser.

The inconveniences and loss accruing through the variety of customs to which copyright lands are subject have led the legislature to make provision for their gradual extinction. By the copyhold commissioners all the services due to the lord of the manor may be commuted for a fixed rent. The lord is also authorised to enfranchise or convert into freehold the lands by agreement with their owners. Since 1853 either the lord or the tenant so admitted may compel enfranchisement on payment, either of a fixed sum where it is at the instance of the lord, or of an annual rent where it is at the instance of the tenant, fixed in both cases by the commissioners. The copyhold commissioners are now incorporated with the Inclosure Commissioners and the Tithe Commissioners, under the name of the Land Commissioners for England, who publish an annual blue-book. Upwards of 16,000 enfranchisements have been made, the compensation amounting to considerably above £2,000,000.

Copying is a term in general use for a great many different processes, but may be described generally as the reproduction, usually either on an enlarged or reduced scale, of any drawing, map, or other work of art. A few of the methods employed may be shortly described. If the copy is to be the same size as the original, the easiest way is to trace it. A piece of tracing-paper (which may be bought at any stationer's) is put over the drawing, and the

principal lines gone over with pencil. The back of the tracing is then rubbed with black lead or ruddle, and put on the clean paper on which the copy is to be made; the traced lines are gone over with a hard point, and thus indicated faintly on the paper. Guided by the traced lines, the copy can then be drawn in. It is usual to have the ruddle or black lead on a separate piece of thin paper, and interposed between the tracing and the paper. When the copy is required of a different size from the original, the simplest way is to sketch it by hand and eye, but where more mechanical accuracy is required, the method of squares is very useful. The original is covered with squares of any convenient size by pencil lines or threads; a piece of paper for the copy is prepared with a corresponding number of squares, of a smaller or larger size, according as the copy is wanted smaller or larger. These squares must bear the same proportion to the squares on the original, as the copy is to bear to the original. It is then a comparatively easy matter to copy in each square the part of the original in the corresponding square. To avoid confusion if the squares are small, it is well to number them along each side of the drawing. If it is not convenient to cover the original drawing with pencil lines, or to tie threads over the face of it, a very good way is to draw the squares on a piece of tracing-paper, and put that over the original; the same tracing-paper will do any number of drawings. A pair of proportional compasses (see COMPASSES) will be found very useful for fixing the proportional size of the squares. Any drawing consisting principally of straight lines, such as a plan, can be conveniently reduced by constructing a scale to suit the reduced size required. The lines of the original are measured by its scale, and the same proportion of the smaller scale gives the necessary measurement. The Pantograph (q.v.) is another means of making a reduction or enlargement, but is very seldom used now. It is only accurate in a general way. Perhaps the simplest and most exact method is to get the original photographed to the required size; the copy can then be traced on to clean paper as already described.

The copying of letters and other documents for commercial purposes is usually done by means of the ordinary copying-press, which is so familiar in every counting-house as to need no detailed description. A letter written with specially prepared ink is transferred to another piece of paper by means of damp and pressure. Common ink thickened with a little sugar will serve as copying-ink. Many modifications of this arrangement have been devised for producing a number of copies of circulars, &c. from one written copy, and are known as 'graphs' (hektograph, &c.). A document written with the ink prepared for the purpose is transferred by pressure with the hand to a gelatinous slab, from which as many as fifty or sixty copies, more or less distinct, can be retransferred by rubbing with the hand. A very useful method of manifold writing is largely employed in telegraphic news work, and for duplicating invoices by retail tradesmen. Carbonised paper is put between two or three or more sheets of thin paper ('flimsy'), and thus, whatever is written on the top sheet by a hardish pencil is duplicated on the others. When an indefinite number of copies of any drawing or other subject is required, there are many printing processes which may be employed. Letters or circulars, if written with lithographic ink, can be transferred to stone, and any number printed. Engineers' or architects' drawings, or any other drawing executed in *line*, can be very successfully reproduced in any size by the photo-lithograph process, which will be described under LITHOGRAPHY. If required for block or letterpress printing, then

any of the zincotype processes may be employed. By this process, also, plates to reprint steel-engravings can be produced from any printed engraving (see ENGRAVING). For reproducing drawings executed otherwise than in line, photographs from nature, or paintings, there are many processes which will also be described in the same article.

Copying in photography, that is, the method of copying pictures and other drawings by the camera, will be described under PHOTOGRAPHY.

Drawings for wood-engravings are now seldom made directly on the wood, but executed on paper or cardboard, and copied by photography on to the wood. By this means the drawing need not be so minute as the required engraving, but may be of any convenient size. The process employed will also be described under PHOTOGRAPHY.

Copyright is the exclusive right to multiply copies of a written or printed composition, or of a work of art. Such rights were claimed by authors even before the introduction of printing. After the invention of the printing-press, the right to publish books became the subject of licenses and patents. In Chambers's *Domestic Annals of Scotland*, under date November 9, 1699, may be seen a warrant of the Privy-council authorising George Mossman, stationer in Edinburgh, 'to print and sell the works of the learned Mr George Buchanan, in one volume in folio, or by parts in lesser volumes, and forbidding all others to print, import, or sell the whole or any part of the said Mr George his works, in any volume or character, for the space of nineteen years.' Similar privileges were granted in England; but all such monopolies were regarded with suspicion by common lawyers. The common law affords a certain measure of protection to works unpublished, or published only for a limited purpose. The writer of a letter, for example, transfers his property in it to the receiver; but the receiver has no right to print it for sale or distribution without the writer's consent. The copyright in published works is the creation of statute: the first Copyright Act was passed in 1709, and by virtue of its provisions authors acquired the sole liberty of printing their books during a term of fourteen years from first publication, and, if the author should be living at the end of that time, during a further term of fourteen years. While this act was in force, Thomson sold the copyright of his poems to Millar, a London bookseller. Millar claimed the right to prevent the issue of reprints by Donaldson (of Edinburgh) and others, even after the statutory term had expired, on the ground that an author had, at common law, the sole right of printing his works. Out of this dispute arose the famous cases of *Millar v. Taylor*, and *Donaldson v. Beckett*, which led to a remarkable difference of opinion among the judges. The House of Lords decided that, if any common-law right existed, it had been taken away by the statute.

At the union with Ireland, the Copyright Act was extended to that country, and the trade in cheap editions, printed in Dublin and secretly imported into Great Britain, came to an end. In 1814 the term of copyright was extended to twenty-eight years, and the residue of the author's life if he were living at the end of the term. The impetus given to literature at the beginning of the present century, and especially the popularity attained by the works of Scott and Byron, greatly increased the market value of copyright, and ultimately led to further legislation in the interest of authors and publishers. The basis of the existing law is the Copyright Act of 1842, commonly known as Talfourd's Act or Lord Mahon's Act. Macaulay's speech in the House of Commons on the second reading of this measure is one of his most successful

parliamentary efforts. The law of copyright is still far from being settled; the acts which relate to the subject are extremely ill drawn. In 1878 a Royal Commission recommended 'that the law on this subject should be reduced to an intelligible and systematic form.' Pending the execution of this useful design, the provisions of the existing law may be summarised as follows.

Books.—The term of copyright in books is forty-two years, or the life of the author and seven years, whichever of the two terms is the longer. No copyright can be enjoyed in seditious or immoral publications, or in books first published out of the United Kingdom. A register of proprietors of copyright is kept at Stationers' Hall, in which the owner of a copyright may make an entry on payment of a fee of 6s. Assignments may be made by entry in the register. Non-registration does not affect the copyright, but only the right to sue in respect of the infringement thereof. In case of infringement, the owner of copyright may obtain an injunction from the High Court (in Scotland, an interdict from the Court of Session) to restrain the issue of unauthorised copies; he may also bring an action and claim damages. In such proceedings the defendant frequently pleads that he has made only a fair use of the plaintiff's work. The question, what is a fair use, is a question of common sense, rather than of law. An author may resort to previous works for facts and ideas; he may extract or abridge the copyright composition of another, provided he does not actually copy it, or an unreasonably large part of it, into his own book. Authors complain that the law as it stands does not sufficiently protect them against unfair use of their materials and ideas. The crown is said to have the sole right to authorise the printing of Bibles, copies of the Book of Common Prayer, the Westminster Confession of Faith and Catechisms, and acts of parliament. The universities are permitted to enjoy perpetual copyright in works bequeathed to them. For government publications, see BLUE-BOOKS.

Encyclopaedias and Periodicals.—Articles contributed to publications of this class, and books published in parts or series, belong to the proprietor. But the proprietor may not publish them separately without the writer's consent, and after twenty-eight years the copyright reverts to the author.

Dramas and Musical Pieces.—These, if first published in book-form, are subject to the same rules as books. But if they are performed in public before appearing in print, the author retains the sole right of permitting them to be represented during the term of copyright; and this right is distinct from the copyright he acquires if his drama or piece is published as a book. By an Act of 1882 the proprietor of a piece of music, desiring to reserve the right of performance, must give notice to that effect on the cover. Verses may not be taken from a copyright work and set to music, for sale, without permission. A novel may be dramatised without the author's permission; but if copies of the drama are published containing passages borrowed in substance from the novel, the author of the adaptation is liable to an action. In the 'Little Lord Fauntleroy Case' (1888), the right to dramatisate was admitted, but it was held that the authoress could restrain the publication of copies containing passages which were taken from the novel without alteration. Even distribution of copies to the Lord Chamberlain and the actors was held an infringement of her rights; so that the right to dramatisate can only be exercised with precautions which must greatly restrict it in practice.

Lectures and Speeches.—If a person delivers an address to the general public, he has probably no cause of action against any one who publishes a report of what he says. But a person addressing a

limited audience for a limited purpose (as e.g. a professor instructing his class) may prevent the publication of unauthorised reports. See the case of *Caird v. Sime*, which was decided by the House of Lords in 1887. An Act of 1835 imposes penalties on persons printing and issuing spoken addresses without the consent of the author; but the act is so drawn that its scope and effect are somewhat doubtful.

Letters.—The copyright in a letter, as already mentioned, is retained by the writer, unless he indicates his wish that it should be published. In the absence of such indication, the receiver has no right to publish or even to sell it as a curiosity.

Newspapers registered under the Copyright Acts are copyright, but, in practice, news and even editorial matter are copied with great freedom from one newspaper into another. The adoption of an existing newspaper title, or the colourable imitation of it, is a good cause of action.

Engravings, Maps, &c.—Copyright in these is secured by several acts: the term is twenty-eight years. Each plate and print must bear the name of the proprietor. Copyright in paintings, drawings, and photographs is secured to the artist during his life and seven years after by an Act of 1862. A register of proprietors of copyright in paintings, &c. is kept at Stationers' Hall, and no action can be maintained in respect of anything done before registration.

Colonial Copyright.—The Act of 1842 extended the copyright of books printed in the United Kingdom to all the colonies thereof. Complaints were made as to the operation of this rule, and in 1847 the Foreign Reprints Act enabled the colonies to import foreign reprints of British books, on making due provision for the rights of authors. So far as authors and owners of copyright were concerned, the act proved a failure. In 1874 the Canadian Copyright Act (confirmed by the imperial parliament in 1875) enabled a British author to obtain copyright in Canada for twenty-eight years, provided his work should be published or republished in the colony. This right is concurrent with and in addition to the rights given by the imperial Act of 1842.

United States.—The American law permits authors, designers, &c. to acquire copyright for twenty-eight years; a further term of fourteen years may be secured by the author, if alive, or by his widow or children. Copyright can only be acquired by a citizen of, or permanent resident in, the United States. British authors have much reason to complain of this state of the law; and American authors are injured by having to compete with cheap unauthorised reprints of British works. American authors have endeavoured to secure copyright by simultaneous publication in America and England; but the legal effect of this is somewhat doubtful. In the present work, many of the articles, written by United States citizens, are copyrighted in the United States. There was at one time an understanding that the American publisher who first placed a British work on the market obtained copyright by courtesy; and considerable sums have been paid for 'advance sheets' in order to obtain this advantage. But the 'courtesy of the trade' has of late been disregarded. Authors and publishers have for some time been disposed to acquiesce in legislation for the protection of British authors; but the American printers objected. A bill was in 1888 presented and passed through the senate, which would have enabled a foreigner to obtain copyright in the States, provided his work was printed there, before being copyrighted there or elsewhere. This bill, which was as alarming to British printers as previous proposals were to the American printers,

did not become law. The United States did not join the Bern Conference (1885). See also *BOOK-TRADE*, Vol. II. p. 316.

International Copyright.—An act was passed in 1844 which enables foreign authors and artists to secure copyright in Britain for their works, provided due protection has been secured by the country in which such works were produced for the benefit of those interested in similar works published in Her Majesty's dominions. An international conference was held at Bern in 1885. The conference comprised Britain, Germany, France, Spain, Switzerland, and Sweden and Norway; and an Act of 1886 empowered the Queen to accede to the convention then prepared in draft.

Foreign Laws.—It is not possible here to give details of the formalities required by foreign copyright laws. But the term of literary copyright has been so much discussed that it may be interesting to note the provisions of foreign laws on this point. The term in France is life and fifty years; in Belgium, life and twenty years; in Germany, life and thirty years; in Italy, life and forty years (with a further term of forty years, during which the proprietor is entitled to a royalty). In Russia, Spain, and Portugal the term is life and fifty years; in Holland, life and twenty years.

The policy of the copyright laws and the amendments required are discussed in the Report of the Royal Commission of 1878. See also Jerrold's *Handbook of English and Foreign Copyright*, and the works of Scrutton, Copinger, Shortt, and Bowker, on the laws of copyright; and Constant, *Code Général des Droits d'Auteur* (1888).

Copyright in designs is protected by the Patents Act of 1883. See the articles *DESIGN*, *PATENT*, *TRADE MARKS*.

Coquelin, BENOIT CONSTANT, actor, born in 1841 at Boulogne, where his father was a baker, was admitted to the Conservatoire in 1859, and having gained the second prize for comedy, made his debut at the Théâtre Français, December 7, 1860, as Gros-René in the *Dépit Amoureux*. For over a quarter of a century he played here with unbroken success, both in classical pieces and in rôles created by himself; in the broader aspects of comedy, standing without a rival. He left the Théâtre Français in 1886, and appeared in 1887 in London, in 1888 in South America and the United States.

Coquerel, ATHANASE LAURENT CHARLES, an eloquent minister of the French Reformed Church, was born in Paris in 1795. He studied theology at Montauban, and became in 1818 minister of the French church in Amsterdam, but came to Paris in 1830, on the invitation of Cuvier, and preached here until his death, 20th January 1868. In 1848 he was elected a delegate to the National Assembly by the department of the Seine. His writings, all marked by earnestness and liberal sympathies, include a reply to Strauss (1841), six collections of sermons (1842-56), and *Christologie* (1858).—His son, **ATHANASE JOSUE LAURENT**, also a Protestant pastor of liberal tendencies, was born at Amsterdam in 1820. A still more 'advanced' theologian than his father, he found himself at variance with the Protestant Consistory and the predominating influence of Guizot in his somewhat rigidly orthodox old age. He died at Fismes, in Marne, 25th July 1875. Among his works were an edition of Voltaire's letters on toleration (1863), and *Jean Calas et sa Famille* (1857).

Coquilla Nut, the fruit of a Brazilian palm, *Attalea fimifera*. On account of their large size (3 to 4 inches long) and the hard texture and beautiful mottling of their dark brown endosperm, they are imported by button-makers and turners.

Coquimbo, also called LA SERENA, capital of a province of Chili, stands near the mouth of the river Coquimbo, on three terraces. It is a handsome town, with a new cathedral, seminary, lyceum, and hospital. Pop. 14,000. The port of Coquimbo is on a bay, 6 miles SW., and has a population of 5000. It exports copper, silver, and manganese ores, wool, cattle, hay, and cobalt.—The province of Coquimbo occupies the entire breadth of the country from the sea to the Andes. Its area is 12,855 sq. m.; pop. (1885) 176,244. The rainfall is small, save in the south, where some farming is carried on. The main occupation is mining of copper, as also silver and gold. See CHILI.

Coqui'to (*Jubea spectabilis*), a beautiful Chilian palm, of which the sap is boiled down as syrup (*miel de palma*).

Coracias. See ROLLER.

Coracle, CURRACH, or COURACH (Celt. *corrag*, *curach*; Lat. *curuca*, *carroccium*, *carabus*), the name given in the British Islands to a canoe or boat made of a slender frame of wood or wicker-work, and covered with skins. Skiffs of this sort, as well as canoes hollowed out of the trunks of oaks, were in use among the Britons in the earliest times of which we have record. Julius Cæsar, who built some of them after the British model, tells us that the keel and gunwales were of light wood, and the sides of wicker covered with hides. The first occurrence of the name seems to be in Gildas, who wrote in the 6th century; he speaks of the coracle as in use among the Scots and the Picts. A long voyage in the North Sea, made in a coracle, during the same century, by one of the companions of St Columba, is commemorated by Adamnan, who died in 704. In 878 three Irish missionaries sailed in a coracle from Ireland to Cornwall; the voyage occupied seven days; and the size of the coracle is indicated by the remark that it was one of two skins and a half. An old Life of St Patrick speaks of a coracle 'of one skin, with neither helm nor oar.' The coracle of a larger size had a mast and sail. The coracle still continues to be used on the Severn, and on many parts of the Irish coast, especially on the shores of Clare and Donegal. The last coracle known to have been used in Scotland is in the museum at Elgin. It was employed on the Spey towards the end of the 18th century. Shaw's *History of Moray* (1775) describes the coracle, which had then become rare, as 'oval in shape, near 3 feet broad and 4 long; a small keel running from the head to the stern; a few ribs placed across the keel, and a ring of pliable wood around the lip of the machine. The whole is covered with the rough hide of an ox or a horse; the seat is in the middle; it carries but one person, or, if a second goes into it to be wafted over a river, he stands behind the rower, leaning on his shoulders. In floating timber, a rope is fixed to the float, and the rower holds it in one hand, and with the other manages the paddle. He keeps the float in deep water, and brings it to shore when he will. In returning home, he carries the machine on his shoulders, or on a horse.' One who figures in the *Duncead*—Aaron Hill the poet—by showing the Strathspey Highlanders how to make their timber into a navigable raft, hastened the disappearance of the coracle from Scotland. A boat of bison skin, essentially the same with the

Coracle.

British coracle, is in use among some of the Indians of North America.

Coracoid, an important paired-bone in the breast-girdle, forming along with the scapula the articulation for the fore-limb, and always lying ventrally. In the lower fishes the entire girdle is cartilaginous; in the bony fishes distinct coracoids first appear; they are well seen in Amphibia and in all reptiles except snakes; they are very large and strong in birds; but become mere processes of the scapula in mammals. They very often exhibit a special anterior portion known as the pre-coracoid. See BIRD, SKELETON, Huxley's *Anatomy of the Vertebrates*, and such comparative anatomy text-books as those of Gegenbaur and Wiedersheim (translated by Professors Bell and Parker).

Corais (Fr. CORAY), ADAMANTIOS, a learned Hellenist, was born at Smyrna, 27th April 1748. He early abandoned hereditary mercantile pursuits to devote himself to letters at Paris, where he lived till his death, 6th April 1833. He published editions of many ancient Greek authors, as the *Æthiopica* of Heliodorus, and laboured all his life to promote Greek learning and the feeling for Greek patriotism. His *Atakta, ou Mélanges sur la Littérature Grecque Moderne* (5 vols. Paris, 1828-35) is a work of great value. His autobiography was published at Paris in 1829-33; his posthumous papers and letters at Athens (5 vols. 1881-87).

Coral, a term loosely applied to any animal in the class Coelenterata which forms a hard skeleton. The tubular organ-pipe coral, the noble or red coral of commerce, and the reef-building madreporé corals, are familiar examples. Presuming an acquaintance with the general features of the class, as summed up in the article COELENTERATA, we may notice at the outset the fact that the formation of hard supporting structures is exhibited in very varied degrees, in manifold styles of architecture, and in widely separated forms.

Different Kinds of Coral.—(1) Among the Hydrozoa the skeletal investment of the polyp

Fig. 1.

A, branch of Dendrophyllia; B, part of a stock of red coral, with (a) fully extended polyp, and (b, b) two polyps, partly extended.

types, when present, is usually horny. In one subdivision, however, the supporting framework is limy, and to these forms—Millepores (q.v.) and Stylasterids—the title Hydrocorallina is fitly applied. (2) It is, however, in the other sub-class

of Coelenterates—the Actinozoa—that the formation of coral structure becomes emphasised and perfected. In many simple and in most colonial forms, a skeleton is formed, as isolated spicules or continuous. When continuous it may be horny, or limy with an organic basis, or to all appearance entirely limy. (a) Among the Alcyonaria, of which Alcyonium (q.v.) is a convenient type, Tubipora, with the spicules united to form tubes and crossing platforms; Corallium, with a branched axis of fused spicules; Isis, with a jointed axis alternately limy and horny; Heliopora, with limy cups inclosing the individual animals, and traversed as they grow by successive horizontal floors at slight intervals, are examples of different forms of coral occurring in distinct groups. (b) Among the Zoantharia, of which Actinia or any sea-anemone is a familiar example, the Actinaria have no skeleton, and therefore include no coral forms; the Antipatharia have a varied non-calcareous supporting skeleton, and include some forms known as 'black corals'; the third subdivision, the Madreporaria, always have a continuous limy skeleton, and include the best-developed corals. Most madreporae are colonial, and the common connecting skeleton is either solid (apart from mere gaps) or perforated by canals which establish community of life between the individual members. Hence it is usual to distinguish two sections of Madreporae as Aporosa and Perforata. (3) The earliest corals of Palaeozoic strata—the Rugosa or Tetracoralla—are distinguished by four primary partitions.

General Structure.—In discussing further the general structure, it will be convenient to leave the widely separated Hydrocorallina out of account. The most general fact that can be stated at the outset is, that with the possible exception of the sea-pens, the cells which form the skeleton are at least originally epidermic. Free spicules, connected lattice works, solid cups, illustrate various degrees of lime deposition; while supporting axes, ensheathing tubes, and what look like tolerably

complete casts of the entire animal, are the main types of coral architecture. In detail, however, those main types vary widely, and in the cup-corals especially, the structure is often very complex. In a simple madreporae coral, representing a single individual, the following structures are at once obvious. The main cup-like mass, known as

Fig. 2.—*Caryophyllia borealis*, single individual.

the *theca*, is usually attached by its base to some foreign object. A terminal depression—the *calyx*—contains the animal, the soft parts of which extend more or less over the lips. Within the cup, when the animal has died away, radial partitions are seen, forming various systems of *septa*. Some of these often meet in the middle of the cup to form a central pillar or *columella*. When the coral is colonial, as is generally the case, complications arise by the fusion of individuals. The deeper parts of growing corals are sometimes separated off by cross partitions (*tabulae*), but this is rare in the Zoantharia. In large masses of madreporae certain portions of the skeleton are often left behind by the animals, and being exposed to the water,

become corroded and altered. In regard to the development of corals, it is hardly possible yet to make any useful general statements. For the animals themselves, it must be enough here to refer to the articles on ALCYONIUM and ANEMONE, which, though not themselves 'corals,' are good examples of the two sub-classes to which most corals belong.

General Life.—Corals are predominantly passive forms, and are much modified by their environment (currents, &c.); the great majority are permanently fixed, except in embryonic life. Flabellum may be noted as an instance of a coral-cup which becomes free as an adult. The limy material which forms the skeleton seems, in many cases at any rate, to be derived not from the water, but from the minute animals which constitute the food. The great majority are colonial, yet cases of division of labour are very rare. Many corals are richly coloured, but the meaning of the numerous pigments is still imperfectly known. Masses of corals furnish browsing ground for crowds of animals, not a few of which intrude into the colonies, while others have become established parasites. Some corals also include parasitic Algae (see SYMBIOSIS). Semper describes some very interesting cases of the constant association of worms and corals, and notes how the guest has permanently modified the host (see COMMENSALISM). It is interesting to notice, apart from actual modification of form, how various worm-organisms act upon the 'sea-meadows of coral' much as earth-worms do upon land-meadows (see Huxley's *Invertebrates*, p. 171).

In most corals the sexes are separate, and even the colonies may be entirely male or female. In Corallium, hermaphrodites may occur, or different branches be of either sex. As is common in sessile passive organisms, asexual or vegetative reproduction is a marked feature. Semper considers the budding of the Fungia colony as illustrating 'alternation of generations.'

Distribution.—Of the madreporae corals, the 'solitary' forms, which never form great masses, are for the most part widely distributed deep-sea animals, while the reef-builders are as markedly dwellers in shallow water, from the low-tide mark to about 20 fathoms, and are limited to warm waters. They are not found on the western coasts of Africa and America. In the waters of the Central Pacific reef-corals are found in greatest profusion and variety; but those of the Red Sea, Indian Ocean, and East Indies are not far behind. Over eighty fossil genera of the Palaeozoic Rugosa are known, and of the other Actinozoan corals, about 1800 fossil, and as many living species. Of these, the vast majority are madreporae, and only a small number Alcyonarian. Both sets begin in Silurian times, but were for long outnumbered by the Rugosa. Most existing genera date only from the Tertiary period. The 'areas of past distribution of coral-reefs in no way correspond with those distinctive of the modern seas.' See Heilprin, *Distribution of Animals* (1887).

Important Forms.—The most important corals are the reef-builders (Porites, &c.). The delicate colour, exquisite architecture, and labyrinthine complexity make the limy skeletons beautiful objects. Yet more beautiful, however, is the wealth of colour often exhibited by the living forms. Caryophyllia is a simple and solitary cup-coral found on the south coast of England. Bathyactis and Deltocyathus are almost world-wide. Antipathes—the black coral—has a valuable hard axis like ebony. Fungia is worth noting on account of its flat mushroom-like shape and Semper's observation (see above) in regard to alternation of generations; among Alcyonarian

forms may be noted the blue coral (*Heliopora cerulea*) of many Pacific coral-reefs, the horny and beautifully coloured sea-fan (*Gorgonia flabellum*), and the familiar organ-pipe coral (*Tubipora musica*).

More important, however, in practical interest is the red coral (*Corallium rubrum*) of commerce. In this coral the limy spicules are fused to form the familiar solid axis. The most important banks are those of Algiers and Tunis, and off the Sardinian, Sicilian, and Balearic islands. Great quantities are fished near Naples, and at Sciacca in Sicily. The coral is roughly dredged, freed from its rind, assorted according to colour, and manufactured in Naples, Leghorn, Genoa, &c. Pale rose-coloured coral, not spoilt by the boring of worms and other intruders, has fetched £12, 10s. per ounce. The industry is a very important one, though in recent years it has seriously declined. The most important markets are in Asia, Africa, parts of Russia, Japan, and South America.

CORAL ISLANDS is the name given to certain low islets which are composed for the most part of the calcareous skeletons of various kinds of corals. An *atoll* or typical coral island consists of a somewhat ring-shaped reef inclosing a lagoon. Such reefs vary in size from less than a mile up to 90 miles long and may be 10 miles wide—the breadth of the annular reef being on an average about a quarter of a mile. *Barrier-reefs*, which have a similar breadth, are found surrounding islands or bordering mainlands, from which they are separated by a navigable channel. *Fringing-reefs*, on the other hand, extend outwards from the shore, with no separating lagoon-channel. In the case of atolls and barrier-reefs there is generally a navigable passage through the reef into the lagoon or lagoon-channel, which is kept open by the scour of the tide. It is upon atolls or barrier-reefs that islands occur. Only very rarely, however, are these islands co-extensive with the reef—generally they appear as longer or shorter belts, forming a series of islets straggling along its surface. As reef-building corals do not flourish in water having a lower temperature than 68° F., they are necessarily restricted to tropical and subtropical seas—from many regions of which, however, they are excluded by the presence of cold currents coming from extra-tropical latitudes, by the muddy character of the water opposite the mouths of large rivers, and by other causes.

The rock of a coral-reef is a white limestone composed chiefly of masses of corals, coral debris, and sand, together with the hard parts of molluscs, echinoderms, bryozoans, and calcareous algae. Not infrequently this rock has been changed by the chemical action of percolating water into a compact or crystalline mass, which has lost all, or nearly all, trace of its organic structure. Chamisso (q.v., known also as a poet), the naturalist who accompanied Kotzebue the Russian navigator in his voyage of discovery into the South Sea in 1815-18, appears to have been the first to show how such reefs are converted into dry land. He describes how the polyps cease to grow when they reach the surface of the sea, and how the reef, exposed at low-tide, by and by becomes disintegrated, while broken coral debris is heaped up by the action of the breakers so as eventually to form a high bank which can only be covered during spring-tides. This bank of coral blocks and debris solidifies in time, and remains exposed to the fierce heat of the sun, so that the mass shrinks and cracks, and flakes are detached from it, and raised one upon another by each returning tide. 'The always active surf throws blocks of coral (frequently of a fathom in length and 3 or 4 feet thick) and shells of marine animals between and upon the foundation-stones; after this the calcareous sand lies undisturbed, and offers to the seeds of trees

and plants cast upon it by the waves a soil upon which they rapidly grow to overshadow its dazzling white surface. Entire trunks of trees, which are carried by the rivers from other countries and islands, find here at length a resting-place after their long wanderings: with these come small animals, such as lizards and insects, as the first inhabitants. Even before the trees form a wood, the real sea-birds nestle here; strayed land-birds take refuge in the bushes; and at a much later period, when the work has been long since completed, man also appears, builds his hut on the fruitful soil formed by the corruption of the leaves of the trees, and calls himself lord and proprietor of this new creation.' According to Professor L. Agassiz, the large blocks torn off by the breakers are loosened not by shrinkage under the sun's heat, as Chamisso supposed, but by the innumerable perforations of various boring molluscs.

The origin of coral-reefs is a question which has at various times given rise to discussion. According to Chamisso, the corals commenced to grow on shoals in the sea—on the tops of submarine mountains in short. The circular form of the atoll and its basin-shaped lagoon he believed to be due to the natural growth of the coral. The most vigorous growth took place upon the outward edges of the reef, where the largest and most massive corals flourished. In the interior the coral growth was hindered by the accumulation of shells, coral debris, and sand swept forward by the waves. The reef, therefore, as it approached the surface would gradually assume a basin-shape—the outer edges, or peripheral and actively growing portion, forming the reef—the interior part, where growth was retarded or prevented by sediment, &c., forming the lagoon. Other writers attempted to account for the annular form of atolls by supposing that the reefs had grown upwards from the crests of submarine volcanic craters. The not infrequent occurrence of volcanoes and volcanic islands in the coral regions of the Pacific Ocean was thought to favour this supposition, but the enormous diameter of many atolls seemed to preclude the possibility that these larger atolls, at all events, could be founded on the lips of submarine craters. And when at length it was discovered that reef-building corals flourish only in comparatively shallow water, this hypothesis was rejected, since it was extremely unlikely that so many submarine volcanic mountains should rear their summits just to the limits within which the corals could begin their superstructures.

Darwin, during the famous voyage of the *Beagle*, was naturally fascinated by the problem of the origin of these remarkable reefs, and while he admitted that certain atolls might very likely have been formed in the manner described by Chamisso, yet he could not believe it possible that a broad mountain-summit lay buried at the depth of a few fathoms beneath every atoll, and nevertheless that throughout the immense areas occupied by many of those reefs not one point of rock should project above the surface. The theory of subsidence which he subsequently advanced seemed to account for all the phenomena, and until recently it commanded nearly universal assent. According to Darwin, each atoll has passed through the successive stages of fringing-reef and barrier-reef. Since reef-building corals do not thrive at greater depths than 100 feet or thereabout, it is evident that the foundations of a coral reef could not have been laid in deeper water. And as such moderate depths occur only round islands and off the shores of continents, the reef-builders would begin their work by forming at first a fringing-reef. Slow subsidence of the sea-bottom is supposed to have supervened; but while the foundations were being carried down, the corals continued to grow upwards, the

rising of the reef keeping pace with the sinking of the sea-bottom. Thus by-and-by the fringing-reef is converted into a barrier-reef. We have now only to suppose that the movement of subsidence and the labours of the corals continue until the reef-encircled island disappears below the waves, and a complete atoll will be the final result. Darwin's views were illustrated and strongly supported by Professor J. D. Dana, who accompanied the Wilkes exploring expedition round the world in 1838-42, while M.M. Couthouy and Beete Jukes likewise upheld the hypothesis of subsidence. The researches of Professors L. Agassiz and Le Conte amongst the reefs of Florida have shown that Darwin's views are there inapplicable. They attribute the formation of the southern portion of Florida, which consists of a series of concentric barrier-reefs, to the natural growth of the coral alone aided by the mechanical action of the sea—a view which, stated generally, is the same as that held by Chamisso. Professor Karl Semper likewise, after examining the reefs of the Pelew Islands, came to the conclusion that the form of these reefs had been determined by the natural growth of the corals, modified by local conditions, which is just Chamisso's explanation. But Darwin had already expressly stated that some reefs might have originated in the manner suggested by Chamisso; and geologists apparently recognised that the conditions of the great Florida reef were hardly analogous to the isolated atolls which rise from profound depths in the open ocean.

In 1880, however, Dr John Murray, one of the naturalists of the *Challenger* expedition, published another explanation which has given rise to considerable discussion. He returns to the old views of Chamisso, maintaining that reefs have grown up from the tops of submerged and partially submerged banks and mountains. To the objection that it is hard to believe that so many banks and cones should occur just at the proper depth from the surface, Dr Murray replies that it is not necessary to suppose that all the submarine eminences were of equal or nearly equal height. Some may have risen at first above the level of the sea, and subsequently have been reduced by the waves and breakers to the condition of shoals; while others that did not reach to the limits within which reef-builders live may have been brought up to that zone by the accumulation upon them of the hard parts of pelagic organisms. For these forms of life flourish in extraordinary numbers in the surface-waters of the tropics where reefs abound, and as they die, their hard parts falling to the bottom will accumulate there along with the exuviae of creatures living at such depths, until they come to form considerable deposits. This levelling-up of submarine banks to the zone within which coral-builders thrive is the most marked feature in Dr Murray's hypothesis. His further account of the mode in which atolls and barrier-reefs have been formed is a more particular and scientific development of Chamisso's explanation. The growth of a reef is regulated by the food-supply of the corals; those growing on the external parts of the reef are most favourably placed in this respect, consequently they thrive best, and have the advantage over those that are growing in the centre of the reef; and this difference in the rate of growth of the outer and inner areas will be intensified as the reef approaches the surface. Eventually the corals of the interior die, and the dead coral rock is gradually removed by the solvent action of the sea-water which contains carbonic acid. In this manner the reef assumes a basin-shaped form. Fringing-reefs, according to Dr Murray, are converted into barrier-reefs by the simple outward growth of the coral upon a talus of its own debris, forced off from the

edge of the reef by the breakers. The lagoon-channel that eventually separates the reef from the land is formed in the same way as the lagoon of an atoll—namely, by the dissolution and removal of dead coral rock. Professor A. Agassiz published in 1882 an account of his detailed examination of the Tortugas and the Florida reefs, in which he shows how the bottom of the sea in those regions has been gradually raised by the accumulation of the exuviae and skeletons of massive organisms which flourish in prodigious numbers on the sea-floor, forming the submarine plateaus known as the Florida, Yucatan, and San Pedro banks. He thinks it is by the gradual upward growth of such accumulations that the sea-bottom was eventually raised to the zone in which reef-builders thrive. He thus arrived independently at the same general conclusion as Dr Murray.

As recently as 1887 Dr Guppy (q.v.) has given the result of his investigations in the Solomon Islands, and has vigorously supported the hypothesis advocated by Murray. He shows that in those islands we have elevated reefs which exhibit the very structure which we should expect to find if the new view of coral-reef structure is correct. He found some of those islands largely composed of earthy calcareous deposits having the same character and origin as the various volcanic muds and organic oozes which the *Challenger* expedition dredged at depths varying from 100 to 2000 fathoms. These deposits reached to heights of over 1000 feet, and in some cases denudation had exposed an underlying nucleus of volcanic rock. The earthy calcareous beds were covered with a comparatively thin crust of true coral rock. The phenomena described by Dr Guppy thus lead to the belief that many other atolls may have a similar structure. Dr Guppy thinks that the various agencies insisted upon by Semper, Murray, and A. Agassiz—such as currents and tidal scour, solution and the distribution of food-supply, the repressive influence of sediment and the action of the breakers—have each played a part in determining the form of coral reefs. To the objection that some lagoons are deeper than the zone in which reef-corals live, Dr Guppy replies that where the submarine slope is moderate, the water clear, and breakers of no great size, reef-corals may be found flourishing at depths of 50 and even 60 fathoms. Whether the explanation advocated by Murray and Guppy is destined to lead to the total collapse of Darwin's hypothesis, is likely to remain for some time an unsettled question—some writers holding that while Murray's view may be the true explanation of the origin of many atolls and barrier-reefs, it does not forbid the possibility or, as others would say, the probability that many other reefs may really have been formed, as Darwin supposed, during slow subsidence of the bottom.

See COELENTERATES, ANEMONE, ALCYONIUM; text-books of Zoology—Huxley, Claus, &c.; Darwin, Dana, Murray, Guppy, &c. on Coral-reefs, and Semper's *Animal Life*; Moseley and Quelch *Challenger* Rep., vols. ii. and xvi.; for skeleton, Von Koch, *Morphologisches Jahrbuch* (1879-86); for red coral, Lacaze-Duthiers, *Histoire Naturelle du Corail* (1864); for fossil forms, Zittel's *Palaeontologie*; systematic works—Dana, *Zoophytes* (1848-49); Milne-Edwards and Haime, *Hist. Nat. des Coralliaires* (1857-60); Koren and Danielssen, *Nye Alcyonider, Gorgonider og Pennatulider* (1883); Koch, *Monograph on Gorgonida* (Naples Station, 1887).

Coral Fishes (*Squamipennes*), a name applied to a family of bony fishes in the spiny-rayed or Acanthopteroous order. They are tropical forms, abundant about coral-reefs, usually small, with short, deep, often brightly coloured bodies. The family includes the Archer-fish (q.v.), the very beautiful Chetodons, the genus *Chelmo* with

peculiarly elongated snout, and other interesting forms.

Coral Flower, or **CORAL TREE** (*Erythrina*), a tropical and subtropical genus of papilionaceous trees and shrubs, with long racemes of beautiful flowers of a rich dull crimson or a scarlet colour, resembling coral. Some species are thorny, and are hence used for hedges, notably *E. corallodendron* in the West Indies, and *E. indica* in the East. The wood is so light and spongy that it is used not only for portable objects, such as ladders, but even as a substitute for cork.—*Jatropha multifida*, a totally different plant, of the order Euphorbiaceæ, is also sometimes called Coral Tree.

Coralline (*Corallina officinalis*), a limy seaweed, exceedingly common on British coasts, where it adds much to the beauty of the rocky pools. It is a hardy perennial plant, and envelops the rocks and almost any object between tide marks with its beautiful branching fronds. In spring it appears as a thin crust, with a fresh delicate pinkish or purplish colour. With the increasing sunshine it grows into prettily jointed and branched tufts, spreading like brushwood over the surface of the rock. Its purple colour increases in depth, till the plant grows old and begins to die; then the brightness pales, and the limy incrustation finally remains as a white skeleton. The purple colour soon fades on exposure; a bright white light is produced by holding a piece of the alga in a candle flame; an unpleasant smell lingers for years about the dried specimen. The coralline was formerly regarded as an animal, 'since all lime,' Linnaeus said, 'is most truly a product of animals.' But neither for this, nor for its supposed medicinal (vermifuge) virtues was there any warrant. Technically, the common coralline, along with a few other species, forms a genus of alga in the family Corallinaceæ, the section Rhodospirææ, and the group Floridææ. Melobesia is an allied form of similar stony character. It is sometimes used for manuring fields, and is said to have been one of the principal constituents in the mortar of Iona cathedral. The name coralline is sometimes extended vaguely to certain Zoophytes or Hydroids (q.v.). See Landsborough's *British Seaweeds*, Harvey's *Phycologia Britannica*, Johnston's *British Sponges and Corallines*.

Portion of Branch of *Corallina officinalis* magnified.

(From Landsborough.)

Coralline Crag. See CRAG and PLIOCENE.

Coral Rag, or CORALLIAN, a group of the Oxford or Middle Oolites. See JURASSIC SYSTEM.

Coral Sea is that section of the Pacific which stretches between Australia on the west and the New Hebrides on the east. In 1874 the *Challenger* expedition found parts of it to be 14,700 feet deep. See PACIFIC.

Coral Snake (*Elaps*), small venomous snakes in the same family (Elapidae) as the Cobra (q.v.). The typical species (*E. corallinus*) frequents woods and thickets in South America. Their very small mouth makes them less dangerous. The usual colour is rich red with black and yellow transverse bands, and it is an interesting fact that besides the venomous Elaps, at least two other genera occur which are quite harmless. These, Mr Wallace suggests, probably derive advantage from their close resemblance to the venomous forms.

Coram, THOMAS, philanthropist, was born at Lyme Regis, Dorsetshire, in 1667 or 1668. He was

bred a seaman, and rose to be a merchant captain. Already in 1694 we hear of him as settled at Taunton, Massachusetts, and engaged in benevolent work of various kinds. A few years after he seems to have returned to sea, and to have settled in London, after suffering shipwreck off Cuxhaven in 1719. In London he interested himself in the settlement of Georgia, and in planting English artisans in Nova Scotia; but he soon began his long agitation for the foundation of a foundling hospital. Children were first admitted in 1741. Coram's portrait was painted by Hogarth, a warm patron of his scheme. More thoughtful for others than for himself, Coram fell into poverty, from which he was relieved in 1745, by an annuity of £161 contributed by his friends. He died 29th March 1751.

Cor Anglais, a wind-instrument of the reed species, similar in construction to the Oboe (q.v.), to which it has the same relation as the Bass-horn (q.v.) has to the Clarinet (q.v.). It is usually made in the key of F, a fifth lower than the ordinary oboe, and has the same range—viz. from E in the bass stave to B₄ above the treble stave.

Corato, a large town in Southern Italy, on a fertile plain, 25 miles west of Bari. Pop. (1881) 30,428.

Corban, properly an offering to God in fulfilment of any vow. This might either be of some possession devoted to God, redeemable by an equivalent in money, or it might be a pledge to deprive one's self of something lawful in itself, as wine, for a longer or shorter period. A man might so interdict himself by vow, not only from enjoying anything himself, but also from giving it to others, and thus many of the old Jews juggled their consciences into getting rid of natural responsibilities, as the support of decayed parents, and the like. It was this miserable selfishness, under the thin garb of religious hypocrisy, that our Lord rebukes in the Scribes and Pharisees (Matt. xv. 5; Mark, vii. 11).

Corbell, a town in the French department of Seine-et-Oise, on the Seine, 21 miles S. of Paris by rail, with manufactures of clocks, cotton, and paper, and large flour-mills and granaries for the supply of Paris. Pop. 7541.

Corbel, in Architecture, a projection of stone or wood from the face of a wall, used for supporting pillars or other superincumbent weights. Corbels proper were originally plain on the sides and carved on the front only. Such were the Romanesque corbels, which are so numerous and so richly ornamented. The carving at first resembled the end of wooden beams, but gradually all sorts of figures were introduced, chiefly heads of men and animals. Corbels of great size were likewise used to carry the projecting parapets of castles.

Corbel:
Kirkstall Abbey.

Corbet, RICHARD, poet and bishop, was born in 1582, son of a gardener in Ewell, Surrey. From Westminster School he passed to Broadgates Hall (now Pembroke College), next to Christ Church, Oxford. He took orders, and had already enjoyed preferments at Cassington, Oxfordshire, and Stewkeley, Berkshire, as well as a prebend in Salisbury,

when in 1620 he was made Dean of Christ Church at thirty-seven. In 1624 he was appointed to the see of Oxford, and translated to that of Norwich in 1632. Here he died in 1635, and was buried in his cathedral. Corbet's poetry reflects the cheerful and genial temper of the man. His longest piece is *Iter Boreale*, an account of the holiday-tour of four students; the best, as well as the best known, is the *Fairies' Farewell*, a singularly sweet and graceful little poem. Corbet was famous throughout life for his conviviality and wit.

Corbie-steps, or CROW-STEPS, the stepped slopes of gables. This is a Scottish term, derived

Corbie-steps, from a house formerly in the Castle-wynd, Edinburgh.

no doubt from the *corbelled* or projecting character of the steps, and afterwards corrupted into crow-steps from the resemblance of corbelled to corbie or crow. The origin of this mode of finishing a gable probably arose from the steps used for passing from one side of the roof to another—the parapet

defending the passage being stepped in conformity with the slope of the stairs. Crow-steps were the almost invariable finish of Scottish gables from the 14th to the 17th century, and they were also much used on the Continent, especially in the Low Countries.

Cor'chorus, a genus of Tiliaceæ. *C. olitorius* is widely diffused in tropical countries, being cultivated both as a pot-herb (Jew's Mallow) and on account of its fibre. More important, however, in the latter respect, is the closely allied *C. capsularis*, which has long been cultivated for its fibre in China ('Chinese Hemp'); also in India for making *Gunny Bags* (q.v.), and is now of great importance in European manufactures as Jute (q.v.). The Japanese shrub, common in gardens on account of its pretty double yellow flowers, and still frequently called by gardeners *C. japonicus*, really belongs to the Spiræa family of Rosaceæ, and is correctly known as *Kerria japonica*.

Corcyra is the ancient name for Corfu (q.v.).

Corday d'Armans, MARIE CHARLOTTE, known as CHARLOTTE CORDAY, was born at St Saturnin, near Sées (Orne), 27th July 1768. The descendant of a noble family, with Corneille's blood in her veins, she yet welcomed the Revolution, for from Voltaire she had imbibed 'philosophic' theories, from Plutarch ideas of antique heroism. But she was horrified at the monstrosities of the Jacobins; and her hatred of their acts was intensified by converse with a party of proscribed Girondists, who had fled to Caen in Normandy. She resolved to rid her country of one of the heads of the Jacobins, and came with that view to Paris. Whether to slay Robespierre or Marat was an open question; but while she debated the matter with herself, a demand of the latter for two hundred thousand more victims, marked him out for her weapon. Twice she failed to obtain an audience, but on the evening of 13th July 1793 she was admitted on the plea that she had important

news from Caen to communicate. She found Marat in his bath, and her pretended denunciation of the fugitive Girondists, some of whom were her own friends, called forth the remark: 'They shall receive their reward; I will have them all guillotined at Paris.' Straightway she drove her knife to his heart; he died with a stifled cry. Charlotte was at once arrested, and brought before the Revolutionary Tribunal, where she gloried in the act. In the Conciergerie she sat to the artist Hauer; on the evening of 17th July she was guillotined. The executioner held up her head to the multitude, and slapped it; in the sunset the beautiful dead face seemed to blush. See Vatel, *Charlotte Corday et les Girondins* (3 vols. 1872).

Cordeliers ('cord-wearers'), the name applied in France to the strictest branch of the Franciscans (see OBSERVANTISTS) on account of their wearing a girdle of knotted cord. During the Revolution the name was applied to the members of a political club which was instituted in 1790, and assembled in the chapel of a Franciscan monastery. Its leaders included Danton, Hébert, Camille Desmoulins, and Marat, and for a time it rivalled the more famous club of the Jacobins (q.v.). The height of its influence was the period of Camille Desmoulins' journal, *Le Vieux Cordelier*. Soon after the fall of Danton, the Cordelier club lost its influence, and it was insignificant when closed by the Convention in August 1795.

Cord-grass (*Spartina*), a genus of grasses of which one species, *S. stricta*, found in muddy salt-marshes, is used for making ropes, on account of the toughness of its fibre; in the United States it is greatly relished by cattle. *S. cynosuroides*, a prairie-grass of North America, is used in European gardens as a decorative plant.

Cordia'cea are simply drupaceous Boraginaceæ. Some species are valued for their fruit, notably *C. sebestena*, the Sebesten plum, of the West Indies, *C. myxa* of Egypt; others for their timber, as *C. gerascanthus* and *C. scabia*, Spanish elm, princewood, &c. of the West Indies.

Cordierite, DICHOITE, or IOLITE, a natural silicate of magnesia, alumina, and ferric oxide. It crystallises in stout orthorhombic prisms, and is of various shades of blue, sometimes with a tinge of gray or brown. It exhibits the property of dichroism very clearly, often appearing deep blue when viewed in the direction of the vertical axis, but red or yellow when seen by transmitted light at right angles to that direction.

Cordille'ras (lit. 'chains'), a name applied in America to various chains of mountains. The Cordilleras of South America are described under ANDES; and the Rocky Mountains are the Cordilleras of North America. Those of Central America extend from Darien to the north of Mexico, and gradually increase in elevation from the Isthmus of Panama, until they form magnificent plateaus, and reach a height of more than 17,000 feet in Mexico. See AMERICA, MEXICO.

Cor'doba, a central province of the Argentine Republic, mostly pampa land, rising to the Sierras de Cordoba and de Pocho in the west. Area, 55,350 sq. m.; pop. (1887) 380,000. Copper and silver are mined, but cattle-raising and (to a small extent) agriculture are the chief industries. The climate is healthy, but very dry; the temperature ranges from 18° to 107° F.—The capital, Cordoba, lies in the valley of the Rio Primero, 246 miles WNW. of Rosario by rail. It is regularly built, with open water-courses running through the streets, has over 10 miles of tramways, a cathedral with a fine Moorish exterior, 10 other churches, a handsome city-hall, the old university

building, with walls from 4 to 6 feet thick, a national observatory, and noble baths. The university (1613) sank greatly after the expulsion of the Jesuits (1767), until in 1870 several German professors settled here. The town possesses also a national college, a school of art, and an academy of sciences, which publishes a valuable *Boletín*. Founded by Cabrera in 1573, the town was famous during the Spanish occupation as a seat of learning and the centre of the Jesuit missions in South America. It was afterwards falling into decay, but the opening of the railway in 1870, with the transit trade which this brought, has greatly restored its prosperity. In the hot months of December, January, and February, however, the place is a very trying residence. Pop. (1869) about 28,500; (1888) 68,000.

Córdoba, a town of Mexico, 66 miles WSW. of Vera Cruz by rail, in a fruitful valley, 3045 feet above the sea. Formerly important, it sank greatly after the revolution; but in later years it has in some degree recovered its trade. It is surrounded by rich coffee-plantations. Pop. (1880) 11,302.

Cordon, in military operations, is a line of sentries within sight of each other inclosing or guarding any particular space of ground, to prevent the passage of unauthorised persons. If intended to guard against contagious diseases, it is called a *cordon sanitaire*.

Cordon Bleu, originally the 'blue ribbon' which in France supported the insignia of the Order of the Holy Ghost; but playfully transferred to good cooks, who after examination received a medal, also suspended from a 'blue ribbon.'

Córdoba, or CORDOBA, a city of Spain, capital of the province of Cordova, 81 miles ENE. of Seville by rail. It stands on the right bank of the Guadalquivir, here crossed by the Moorish 'Puente Viejo' of sixteen arches, and occupies a slope connected with the Sierra Morena. The old turreted walls inclose gardens and vineyards; but the interior shows narrow and dirty streets. Cordova was from the 9th to the close of the 12th century a Moorish town of the first rank, renowned for its rich mosques and palaces, and still more for its university. Among the principal buildings is the cathedral, built as a mosque in the 8th century, the most magnificent Mohammedan temple in Europe, and converted (1236) into a Christian church. Cordova was at one time celebrated for its manufacture of goat leather, called *cordovan*, whence the term *cordwain*, but that industry is now almost entirely gone from it. Cordovan, still prepared in the Levant, is used in bookbinding and for finer boots and shoes. Cordova has a bishop's palace, a lyceum, a theatre, a fine casino, museum, &c. It manufactures silverware, silk fabrics, paper hats, &c. Called by the Carthaginians the 'gem of the south,' Cordova was (152 B.C.) founded by the Romans as Corduba. Taken by the Goths in the 6th century, it fell (711) to the Moors, in whose hands it remained till 1236, when Ferdinand III. of Castile struck it a blow from which it has never recovered. In 1808 Cordova was taken and plundered by the French. Cordova was the birthplace of the poet Lucan, and the philosophers Seneca and Averroes. Pop. (1885) 48,711.—The province of Cordova has an area of 5190 sq. m., and a pop. (1877) of 401,660. See ANDALUSIA.

Corduroy, a ribbed kind of fustian, a cotton stuff made after the fashion of velvet. See FUSTIAN.

Corea (native name *Chosin*, 'Morning Calm'), a kingdom on the east coast of Asia, stretching as a peninsula from 34° 30' to 43° N. lat., and from 124° 30' to 130° 30' E. long., between the Sea of Japan

and the Yellow Sea, and separated by the Strait of Corea from the Japanese Islands. It has a coastline of about 1740 miles, and a total area of about 90,000 sq. m. The north boundary line is formed by the river Tu-man flowing north-east, and the Am-nok flowing south-west from the watershed of Paik-to-san. The Tu-man, for the last 5 miles of its course, separates Russian Asia from Corea. A belt of land, 5600 sq. m., on the north side has for the last three centuries been constituted a neutral zone between Corea and Manchuria, but is now being gradually encroached upon both from the Chinese and Korean side. The east coast is high, monotonous, and but slightly indented, with very few islands and harbours. The south and west shores are deeply and manifoldly scooped, and beset by numberless picturesque islands. From these island-fringed shores, especially on the west coast, mud-banks extend out to sea beyond sight. While the tide on the east coast is very slight—only 2 feet at Gensan—it increases on the south and west coast in a north direction, rising to 33 feet at Chemulpo. The rapid rise and fall of tides and the vast area of mud left bare at low-water cause frequent fogs, and render the numerous inlets little available except for native craft. On the west coast the rivers are frozen in winter, but the east coast is open the whole winter through. Quelpaert, the largest island, 40 by 17 miles, lies 60 miles S. of the mainland. Port Hamilton, between Quelpaert and Corea, was for a time an English possession, but in 1886 was given to China. The Russians have been credited with a desire to possess the magnificent harbour of Port Lazaref, on the Korean mainland. See the map of CHINA.

Occupying about the same latitude as Italy, Corea is also like Italy hemmed in on the north by alpine ranges, and traversed from north to south by a branch chain. From the north the chain runs close to the coast, till, about the 37th parallel, it trends inland. The chain rises in elevation from the north to the centre, throwing out feelers to the west which break up the country into a series of narrow valleys debouching on the sea. Precipitous on the east, the chain slopes towards the broader west side, which is accordingly the more developed part; though Kyōng-sang province in the south-east is one of the richest in Corea. Corea is on the whole very mountainous. Among the summits are Hien-fung, measured from sea at 8114 feet high, though later travellers deem this height an exaggeration; Mount Popoff, at 37th parallel; Coxcomb, north-east of Seoul (Sŏul), rises to 4800 feet. The mountains are mostly of primary rock; those of Hwang-hai-do are, however, mesozoic, and about the centre are lava and volcanic rocks. The chief rivers on the west coast are Keum, navigable for boats drawing 4½ feet 30 miles up; Han, navigable to a little above Seoul, 80 miles; Tai-dong, navigable to Phiyōng-yang, 75 miles; Am-nok, far the greatest, navigable to above Wi-wōn, 175 miles. Flowing through beautiful well-timbered mountains, the Am-nok has many affluents, and in the summer floods its waters rise to full 40 feet even where a mile or more wide. In the south-east the Nak-tong is navigable for boats drawing 4½ feet for 140 miles up.

The climate is healthy, bracing in the north, but colder in winter and hotter in summer than in corresponding European latitudes. The heat is tempered by sea-breezes, but in the narrow inclosed valleys becomes very intense. The Han is frozen in winter so as to be available at Seoul, where it is 400 yards broad, for cart traffic three months in the year. The Tu-man is usually frozen five months in the year. Various kinds of timber-trees abound, except in the west, where wood is scarce, and is sparingly used; and in other parts the want of coal

has caused the wasteful denudation of many hill-sides. The fauna is very considerable, and besides tigers, leopards, deer, includes pigs, tiger-cats, badgers, foxes, beavers, otters, martens, and a great variety of birds. Among the products are rice, wheat, beans, cotton, hemp, maize, millet, sesame, perilla. Ginseng grows wild in the Kang mountains, and is also much cultivated about Kai-sŏng, the duties upon it, notwithstanding much smuggling, yielding about half a million dollars annually. The domestic animals are few. The cattle are excellent (the bull being the usual beast of burden), the ponies very small but hardy, fowls good, pigs inferior. Iron ores of excellent quality are mined; and there are copper-mines in several places. The output of silver is very small; in 1886 the customs' returns showed the value of gold exported that year to be 503,296 dollars. The principal industries are the manufacture of paper, mats woven of grass, split bamboo blinds, oil-paper, and silk. The total value of the foreign imports in 1887 was £469,260, two-thirds representing cotton goods; the native exports reached £136,666, chiefly beans and cowhides. The foreign vessels entering the treaty ports in 1886 were 557 of 161,901 tons, and clearing 560 of 162,434 tons. Three-fourths of the trade is with Japan, and over a fifth with China; British goods go by way of these countries. Business has hitherto been done chiefly by barter, imports being exchanged largely for gold dust, and Japanese silk piece goods being a current exchange for trade inland; but in 1888 the mint at Seoul was approaching completion, and a beneficial effect on commerce is anticipated from the introduction of a convenient and sufficient coinage. Seoul is connected with Taku and Port Arthur by telegraph.

The population is variously estimated at from eight to ten millions, of a mainly Mongolian type, though some assume that there is a Caucasian element in the stock. Hair not quite black, and even blue eyes and an almost English style of face are met with. The language is intermediate between Mongolo-Tartar and Japanese, polysyllabic and agglutinating. It has an alphabetic system of its own; but Chinese characters have taken the place of Korean in official writing and correspondence. A grammar and dictionary by Ridel were published at Yokohama in 1879. The philosophy of Corea is Confucian, but in spite of great restrictions on Buddhism there are numerous Buddhist monasteries. Evidence of other religion exists in the *miriok*, half-length human figures carved in stone. The government is an hereditary and absolute monarchy, and carried on through three ministers, besides whom are ministers of six departments. Caste is very powerful, and no office of even only local importance is held by others than a noble. There is strictly no well-to-do middle class, those who are not officials being cultivators. In some districts the lower classes live in a very squalid condition, and mud-hovels thatched with straw are the usual houses everywhere; but beggars are rare, and absolute distress is seldom met with. Corea is divided into eight provinces or Do; three on the east and five on the west coast. Seoul, the capital, has a pop. of about 240,000. P'yŏng-yang, 36 miles from the sea, on the Tai-dong, has a pop. of over 20,000. It is the centre of a silk industry, and 20 miles off, at Keum-san, are gold-washings. Kai-sŏng is important as the capital of the old dynasty, and for its cultivation of ginseng.

The earliest records of Corea carry us back to 1122 B.C., when Ki-tze with 5000 Chinese colonists brought to Corea Chinese arts and politics. Down to modern times Corea has remained perfectly secluded. Almost the first knowledge of Corea obtained by Europe was through the shipwreck of some Dutchmen on the coast in 1653. The mis-

sionary De Cespedes had, however, entered Corea at the end of the 16th century, and from 1777 other missionaries followed. In 1835 M. Maubant gained a footing in Corea, but in 1866, after thousands of converts had been put to death, the only three Catholic missionaries left had to flee for their lives. To avenge the death of the Catholics the French sent an expedition, which was, however, repulsed, while a stranded American schooner was burned with her crew in sight of P'yŏng-yang. In 1871 the United States was baffled in the attempt to obtain redress. Japan was the first to effect a footing in Corea in 1876, when a treaty was concluded between the two countries. Corea followed this up by treaties with China and the United States in 1882; with Germany and Great Britain, 1883; with Italy and Russia, 1884; and with France, 1886. The three ports opened to foreign trade are Chemulpo, Fusan, and Gen-san. The new policy has led to discontent; and there was an insurrection in 1884. A rumour that Russia was about to establish a protectorate over Corea in 1888 was officially denied.

See Dallet, *Histoire de l'Eglise de Corée* (Paris, 1874); Oppert, *A Forbiddén Land* (Lond. 1880); J. Ross, *History of Corea* (Lond. 1880); Griffis, *Corea, the Hermit Nation* (New York, 1882); and *Corea, Without and Within* (1885); Lowell, *Chosŏn* (Lond. 1886); W. R. Carles, *Life in Corea* (Lond. 1888).

Coregonus, a genus of fishes in the salmon family, including numerous species found in fresh water and sometimes in the sea, especially near the coast. The body is compressed, the scales are of medium size, the teeth small or degenerate. They inhabit Arctic and north temperate regions, ranging from North America to Siberia. Their haunts are in deep water, except at spawning time; they feed principally on small crustaceans. They are good for eating. *C. oxyrinchus* in the Baltic and the south-east of the North Sea, *C. lavaretus* in the Baltic, *C. fera* in most Swiss lakes, *C. clupeoides* in British lakes (the 'fresh-water herring' or 'powan' of Loch Lomond), *C. pollan* (the 'pollan') in Ireland, *C. lucidus*, &c. (the 'herring-salmon'), and *C. sapidus* or *albus* (the much-esteemed 'white fish') from North American lakes, are common representatives of the genus.

Corelli, ARCANGELO, surnamed 'Il divino,' an Italian musical composer, was born at Fusignano in the Bolognese in 1653. He visited Paris and Germany as a violin-player, but ultimately settled at Rome, where he was warmly befriended by Cardinal Ottoboni. His compositions, including concertos, sonatas, and minor pieces for the violin, mark an epoch in chamber music, and had great influence on later composers, as Bach. A selection of his sonatas was edited by Joachim. He died 18th January 1713.

Corentyn, a river of South America, rising in 1° 50' N. lat., and flowing northward to the Atlantic between British and Dutch Guiana. It forms an estuary 25 miles wide, and for 150 miles is navigable for boats. See GUIANA.

Corfe Castle, a village-borough of Dorsetshire, in the 'Isle' of Purbeck, 4 miles SE. of Wareham. Its famous castle, dating from early Norman times, is the traditional scene of the murder of King Edward the Martyr, by his step-mother Elfrida (979); and more than twenty knights, 'most noble and valorous in arms,' were done to death within its walls by King John. In 1643 it was gallantly defended by Lady Bankes for six weeks against 600 Roundheads. Taken through treachery two years later, it was dismantled; and its beautiful ruins, with their 'hanging towers,' cover nearly 3½ acres. Pop. of parish, 1777. See histories of Corfe Castle by G. Bankes (1853) and T. Bond (1884).

Corfu, the most northerly and largest of the Ionian Islands, at the entrance to the Adriatic Sea, separated from the coast of Albania by a channel from 2 to 12 miles broad, is 40 miles long from north-west to south-east by $\frac{3}{4}$ to 20 miles broad; area, 270 sq. m.; pop., mostly Greeks, 78,024. The island is traversed by mountains, bare and rocky in their upper slopes, culminating in Pantocrator, 2997 feet high, at the north-east end. The surface is largely covered with luxuriant groves of olive, cypress, and ilex. The winters are rainy, the summers hot and dry. The principal products are olives and wine, oranges, citrons, figs, carob, silk, and honey. Maize is the chief cereal, but yields only about a quarter of the consumption. Goats are numerous, but there are no cattle and so no butter, the substitute for which is olive-oil, the principal export of Corfu. Wine is also exported to Austria-Hungary and Italy. There is no proper agriculture. Fishing, too, is left to the Albanians and Italians. The minerals are sulphur, salt, coal, and marble. The principal town, Corfu, having 16,515 inhabitants, is finely situated on the east coast, and has a good harbour in direct steam communication with Alexandria, Athens, Trieste, Italy, and England. Corfu is the seat of a Greek archbishop and of a Catholic bishop, and has a royal palace, an Ionian academy, founded by Lord Guildford in 1823, with a library of 35,000 volumes, a gymnasium, theatre, &c. The town underwent great improvements during the British protectorate, but there is still room for improvement. The ancient name of the island is *Coreyra*, but from its shape it was also called *Drepane*, or 'sickle.' It has been incorrectly identified with the Homeric *Scheria*. About 734 B.C. the Corinthians planted a colony here, which, by its commerce, growing rich and powerful, fought with the mother-country (665 B.C.) the first sea-battle on record. After many vicissitudes, Corfu fell under the Roman dominion (229 B.C.). For the more modern history, see IONIAN ISLANDS.

Cori, a town of South Italy, 30 miles S.E. of Rome, with a population of 5500. It preserves the name and occupies the site of *Coræ*, one of the oldest cities of Latium. The ancient remains still existing include those of the old walls, temples of Hercules and of the Dioscuri, and a fine bridge.

Coriander (*Coriandrum sativum*), an annual plant of the natural order Umbelliferae, with branching stem, 1 to 2 feet high, the lower leaves bipinnate, the upper leaves more compound, and globose fruit. It is a native of the south of Europe and of the East, and has long been cultivated for the sake of its fruit; and has thus become naturalised in some parts of England, although its fruit (coriander seed) is much less used in Britain than in Germany and some other European countries. The whole plant, when fresh, has a very offensive smell; but the ripe and perfectly dry fruit has an agreeable aromatic smell and a sweetish aromatic taste. It is used in medicine as a carminative, and as a corrective of certain purgatives; also in domestic economy as an aromatic, being very often mixed with bread in the north of Europe; spirituous liquors are flavoured with it; and confectioners cover it with sugar to make a well-known kind of comfit. In the south of England it is common to sow coriander and caraway together, the coriander yielding a crop in the first year, and the caraway in years following. Coriander delights in a rich soil, and is much cultivated and used in India.

Corigliano, a town in the Italian province of Cosenza, on the slopes of a castle-crowned hill, 4 miles from the Gulf of Taranto. Pop. 12,271, mostly employed in cultivating the vine and corn.

Coringa, a seaport in Godavari district, Madras, stands at the northern mouth of the Godavari River, 8 miles S. of Cocanada. It has declined much owing to the obstruction of its harbour by a bar, and to its having been twice overwhelmed by a tidal wave—in 1787 and 1832. Pop. 4397.

Corinna (surnamed *Musa*, 'the fly'), a Greek lyric poetess, a native of Tanagra, in Boeotia, who flourished about 500 B.C. She is said to have instructed Pindar, and to have vanquished him in a poetic contest. Only a few fragments of her work remain, collected by Bergk in his *Lyric Poetæ Græci* (Leip. 1843).—Madame de Staël's *Corinne* was an Italian improvisatrice. For her, see Vernon Lee's *Studies of Italy in the 18th Century*.

Corinth, a city of Greece, celebrated in antiquity, situated on the rocky isthmus of Corinth ($\frac{3}{4}$ miles wide, and 262 feet high), which connects the Peloponnesus with the mainland. The city lay under the northern declivity of the mountain (1886 feet high, and forming one of the strongest natural fortifications in the world) on which stood its citadel (Acrocorinthus), and had three harbours, Lechaëum, to the west, on the Gulf of Corinth; Cenchreæ and Schœnūs, to the east, on the Saronic Gulf. Its position, midway between the Ægean and Adriatic Seas, was exceptionally advantageous for trade. It was as easy to transport goods across the narrow isthmus—called by Pindar 'the bridge of the untiring sea'—as it was difficult to round the Peloponnesus. In its western harbour lay the ships of Italy, Sicily, and Spain; and to Cenchreæ came Egyptian papyrus, Libyan ivory, Syrian perfumes, Phœnician dates, Eubœan fruits, and Phrygian slaves. The exports of Corinthian manufacture were chiefly productions of art, such as statues, pictures, vases, pillars, and vessels of metal and earthenware. Syracuse, Molycræ, Solium in Acarnania, Ambracia, Anactorium, Leucas, Coreyra, Epidamnus, Apollonia, and Potidæa were among the colonies of Corinth. At its most flourishing period it is said to have had a population of 300,000, with more than half a million slaves employed in the fleet and in the colonies in the Mediterranean. It was at Corinth that the first triremes were built, and the first naval battle of the Greeks was fought between the fleets of Corinth and its colony Coreyra (see CORFU).

According to legend, the city of Corinth (anciently called *Ephyre*) was founded about 1350 B.C. by the Æolian Sisyphus, whose descendants ruled the country round till conquered by the Dorians under the Heraclid Aletes in 1074. Monarchy was abolished in 748, and an oligarchy of 200 families lasted till 657, when it was overthrown by Cypselus. He and his son Periander (629–585) greatly extended the city's industry and trade. In 582 the old Dorian constitution was restored. Corinth, which had formerly been the ally of Athens, after the Persian wars became jealous of the increasing power and commerce of the Athenians, and joined the league of the Dorian states. It waged an unsuccessful war on Athens in 458, and incited the Peloponnesians to begin (431) the Peloponnesian war (see GREECE). In 395, at the instigation of Persia, it entered into an alliance with Thebes, Athens, and Argos against Sparta, and the 'Corinthian War' began, which ended with the Peace of Antalcidas (387), dividing the supremacy of Greece between Persia and Sparta. Timophanes made himself master of Corinth in 366, but was overthrown and murdered by his patriotic brother Timoleon. The assemblies of the Greeks that appointed Philip and Alexander of Macedon the leaders against Persia, were held at Corinth in 338 and 336. Under the Macedonian supremacy it was occupied by a strong garrison. After the expulsion of the Macedonians it

joined the Achaean league (243), of which it formed part down to 146 B.C., when it was utterly destroyed by the Romans under Mummius. Exactly a century afterwards Corinth was rebuilt by Julius Caesar, new-named *Colonia Julia Corinthus*, and peopled with veterans and the descendants of freedmen; and under Augustus and his successors it quickly became once more 'the citadel and star of Greece.' It reached almost its old importance as a trading and manufacturing town, and centred in itself the traffic that had formerly belonged to Athens and Delos. About sixty or seventy years before its completion by Hadrian, it was visited by St Paul, who, during a sojourn of a year and a half, planted a Christian church in Corinth, to which he addressed two of his epistles. The city was (from 27 A.D.) the seat of the pro-consul of the Roman province of Achaia, and the restoration of the Isthmian Games brought to it multitudes of Greeks from all parts of the Roman empire.

The Corinthians were devoted to the worship of the deities of love and of the sea. Aphrodite's temple was the oldest and the holiest in Greece. In her rites at Corinth, Phœnician influence is distinctly traceable. According to Strabo, in the most flourishing period of the city more than 1000 *hierodouloi* were kept there—'a source of much danger to strangers as of lustre and credit to the service of the goddess.' It was at Corinth, where unbridled licentiousness received such religious consecration, that the Apostle Paul wrote his description of heathen corruption in the Epistle to the Romans. Nowhere in the Hellenic world was licentiousness so prevalent. 'The vices of the Greeks were notorious in the Roman empire, the Corinthian vices even in Greece.' With all the artistic skill and culture of the Corinthians, and the lavish expense at which they adorned their wealthy city, they showed but little creative power in art, and 'among the illustrious writers of Greece, not a single Corinthian appears.' Yet Corinth produced the painters Ardicus, Cleophantus, and Cleanthes; the statesmen Perianther, Phidon, Philolaus, and Timoleon; Arion, the inventor of the dithyramb; and was the abode in his later life of the cynic philosopher, Diogenes.

Corinth was spoiled by Gothic hordes at the end of the 3d century, by Alaric in 396, and by the Slavs in the 8th century. In 1205 it was taken by the Franks, and from them it fell back into the hands of the eastern emperors, from whom in 1459 it was wrested by the Turks. It was held by the Venetians from 1699 to 1715, when it was retaken by the Turks, under whom it sank to a miserable village. After being delivered from Turkish domination in 1822, Corinth slowly increased from 1830 till the 21st February 1858, when it was utterly destroyed by an earthquake. The town has since been rebuilt in a more convenient position, 3 miles to the north-east. Its population is now 3000. A mile and a half east-north-east of New Corinth, on the Gulf of Lepanto (anciently Gulf of Corinth), is the western mouth of the canal through the isthmus. Two new towns have been laid out at its east and west mouths, the eastern named Isthmia, the western Posidonia. See CANAL, Vol. II. p. 699.

Corinth, capital of Alcorn county, Mississippi, on two railways, 93 miles E. by S. of Memphis. Here General Rosecrans gained a decisive victory over the Confederates, October 3-4, 1862. Pop. 2275.

Corinthians, FIRST AND SECOND EPISTLES TO THE, two writings forming part of the New Testament Canon, addressed by the Apostle Paul to the Christian church which he had founded at Corinth (q.v.) during his sojourn there, in part of

52, the whole of 53, and part of 54 A.D. Paul had been succeeded at Corinth by Apollos, and Apollos by certain Judaizing teachers, and the church had become divided into four parties (1 Cor. i. 12). The First Epistle—which contains a reference to another epistle which preceded it, but has not been preserved (1 Cor. v. 9, 10)—was written from Ephesus in the spring of 57 or 58, and was occasioned by the reports which Paul had received from 'those of the household of Chloe' (1 Cor. i. 11) about these divisions. It was intended also to correct various abuses, and answer certain questions which the Corinthian Church had asked him by letter (1 Cor. vii. 1; viii. 1; xii. 1; &c.).

The reports brought by Titus of the condition and disposition of the Corinthian Church, and of the impression made on it by the previous epistle, induced Paul to write the *Second*. In this he appears to many scholars to refer to a second visit he had paid to Corinth (2 Cor. xii. 14; xiii. 1) some time between the first visit and our First Epistle—though by others this supposed second visit is much disputed—urges a collection for the mother-church at Jerusalem (2 Cor. viii. and ix.); endeavours to remove certain scandals that still existed, and to re-establish his apostolic authority, which had been contested by the schismatic teachers; and expresses his intention to pay another visit to Corinth. The epistle was written from Macedonia in the autumn of the same year (57 or 58 A.D.). The two epistles are unquestionably genuine, and show in the clearest light the personal character of the writer and the inner life of the primitive Gentile Church. 'We are here,' says Stanley, 'and (as far as the epistles are concerned) here only, allowed to witness the earliest conflict of Christianity with the culture and vices of the ancient classical world. . . . It is the Apostle of the Gentiles, as it were, in his own peculiar sphere—in the midst of questions evoked by his own peculiar mission—watching over churches of his own creation.'

The best of the special commentaries on both epistles are those of Meyer (6th ed. 1881), Holsten, *Das Evangelium des Paulus* (vol. i. 1880); Godet (English trans. in Clark's Series, 2 vols.); Stanley (5th ed. 1882); and Beet (3d ed. 1885); on the First Epistle singly, those of Heinrici (1880) and Lias (1886); and on the Second, that of Klöpffer (1874).

Coriolanus, CAIUS or CNÆUS MARCIUS, a Roman patrician, surnamed *Coriolanus* from his heroism at the capture of the Volscian town of Corioli (493 B.C.). Of a proud and haughty spirit, he was strongly opposed to the plebeians, who refused to elect him when a candidate for the consulship. After this, during a time of famine, he argued in the senate against a gratuitous distribution of the corn which had arrived from Sicily, unless the plebeians should give up their tribunes, but lately instituted. For this he was impeached, and banished. He took refuge among the Volscians, whom he aided in their war with the Romans. His victories at the head of his Volscian troops alarmed the Romans, who, on his approach to their city, sent a variety of deputations to plead with him. He was deaf to every entreaty. At last, the noblest matrons of Rome, headed by his old mother Veturia, and his wife Volumnia, leading her two children, came to his tent. (Shakespeare follows Plutarch in calling the mother Volumnia, while the wife is Virgilia.) Their tears cooled his fierce desire to be revenged on those who had dishonoured him, and he led back the Volsci to their own territories. Shakespeare's *Coriolanus* is a stately and impressive drama, its hero a magnificent creative realisation of the haughty but noble aristocrat of Plutarch's story.

Cork (Span. *corcho*, from Lat. *cortex*) is the extraordinarily developed corky layer (see below, and article BARK) of the bark of the Cork-tree or Cork-oak (*Quercus suber*) of the Mediterranean. Spain and Portugal chiefly supply the world with cork. The cork-tree is not of great size, generally 20 to 60 feet high, the trunk often 3 feet in diameter, much branched, with ovate-oblong evergreen leaves, entire or serrate. The acorns are edible, and resemble chestnuts in taste. The tree is usually twenty or twenty-five years old before it yields a gathering of cork, and attains an age of 150 years. The first produced (Virgin Cork) is of little value, but is removed in order that the next production may be better, for every successive formation is superior to that which preceded it, and it is not till the third gathering that cork of the highest quality is obtained. About every eight or ten years a crop is taken; but the improvement is being introduced of leaving the loosened cork-layer for some months as a protective jacket upon the tree. The cork-cambium is thus protected from the sun and the attacks of insects, and the new growth is thus both more rapid and of finer quality. In stripping off the cork, longitudinal and transverse incisions are made to the proper depth, and each piece is then cut away from the tree by a curved knife with two handles, like that of a cooper. The pieces are soaked in water, pressed flat, dried, and superficially charred, to remove decayed parts and conceal blemishes, before they are packed in bales for the market. Besides the use of cork for stopping bottles, casks, &c., it is much used, on account of its lightness, for floats of nets, life-belts, &c.; and on account of its impermeability to water, and its being a slow conductor of heat, inner soles of shoes are made of it. All these uses are mentioned by Pliny; but the general employment of corks for glass bottles appears to date only from the 15th century.

The *Spanish Black* used by painters is made by burning cork-parings in closed vessels. Cork-waste is also utilised for many objects, and most largely in the manufacture of linoleum.

The cork-tree is occasionally planted in England; it has been found to do well in some parts of the United States.

The wood of some trees possesses the cellular sponginess, lightness, and elasticity of cork in such a degree as to be sometimes substituted for it in many of its uses, as that of the *Anona palustris* (Corkwood or Alligator Apple) in the West Indies, &c.

As already mentioned under BARK (q.v.), cork is by no means botanically the exceptional product it seems from the practical or popular point of view. The epidermis being usually only a single layer of definitely formed cells, it is insufficient either for covering or protection in almost all conditions of continuous growth and exposure to climate (the mistletoe being rather a less developed type than a true exception among woody plants, since its deeper ordinary epidermic cells never lose the power of multiplication). In sections of the young shoots of

dicotyledonous trees or shrubs this provision for replacing the epidermis can be beautifully traced; a layer of cells just outside the cellular envelope, the so-called cork-cambium, is seen to have already formed an appreciable thickness of cork-cells, easily recognised by their prismatic shape, tolerably regular vertical series, and thin walls. As the stem grows older the epidermis wears off and the cork-layer thickens, while the access of air to the living cellular envelope below is permitted by the occurrence of spaces empty or filled only with looser tissue, the *Lenticels* (q.v.), which, of course, become represented by the deep air-channels so obvious in the inferior quality of cork.

CORK-CUTTING.—The bark, after being cut into square pieces or sheets, is pressed to remove its natural curvature and flatten it. If it is found that simple pressure has not flattened it sufficiently, it is heated on the convex side, and the contraction thus produced straightens it. It is then cut into slips, and these slips into squares, according to the required size of the corks. These are rounded by the cork-cutter by means of a broad sharp knife; the cork is rested against a block of wood, and the knife pushed forward, its edge at the same time being made to describe a circular curve. The knife requires continual sharpening; the workman has a board before him on which the knife is rubbed on each side after every cut. But cork-cutting is now largely done by machinery; in the United States the process has been carried to great perfection. Corking-machines are ingeniously contrived to force the cork into the neck of the bottle, and, if necessary, to wire it down. For *rock cork*, see ASBESTOS.

Cork, a maritime county in Munster, the south-most and largest of the Irish counties. Greatest length from east to west, 110 miles; greatest breadth, 70; average, 34. Area, 2890 sq. miles. Cork is hilly, with great variety of surface. The west part is rocky, mountainous, wild and boggy; the east and south, rich, fertile, and picturesque. The ranges run east and west, except the Boghra Mountains, between the Lee and Blackwater. The coast is bold and rocky, and from its indentations, 250 miles long; the bays, which run 3 to 25 miles inland, admitting large vessels. The chief bays are Bantry, Dunmanus, Baltimore, Glandore, Clonakilty, Kinsale, Cork Harbour, and Youghal. There are many isles off the coast, including Cape Clear Island, which lies in 51° 25' N. lat., and 9° 30' W. long., and, with the exception of a rock 4 miles to the SSW., is the southmost point in Ireland. In the west, Cork is divided from Kerry by a range of Silurian clay-slate running north-east and north, the chief points being 1200 to 2240 feet high. This range sends offshoots to the east, which divide the county into the parallel basins of the three chief rivers of Cork, the Blackwater, Lee, and Bandon: the lower parts of these basins are well cultivated and productive. The Lower Carboniferous limestone forms the largest lowland tracts and valleys of the county. Part of the Munster coalfield occupies 400 sq. m. in the north-west. Cork has many small lakes in the west. One of these lies at the source of the Lee, amid wild, picturesque scenery, with the ruins of a chapel on an islet frequented by pilgrims. The chief mineral productions are coal and iron, copper, barytes, limestone, fine dark-gray and also red marble rich in fossil shells, fullers' earth, brick-clay, marl. There is a thermal magnesian spring at Mallow. The climate is moist, but genial. The soils are calcareous, loamy, and moory. The dairies are extensive, and Cork butter stands in high estimation. The cattle are small in size, but yield large quantities of milk. Of the total area, about 30 per cent. is under crops. The chief manufactures

Formation of Cork in a branch of Black Currant, one year old (mag. 350 diameters):

e, epidermis; b, bast-cells; pr, cortical parenchyma; k, the cork-cells formed from c, cork-cambium. (Sachs.)

are leather, tweed, whisky, porter; and the chief exports provisions. Pop. (1841) 854,118; (1851) 653,180; (1871) 517,076; (1881) 495,607, of whom 90·8 per cent. are Catholics. Formerly Cork county sent two members to parliament, besides two for the city, and four for minor boroughs. Since 1885 the county returns seven members, the city two; and Bandon, Mallow, Kinsale, and Youghal have been absorbed in the county. The antiquities of Cork are stone circles and altars, two round towers, circular earthworks or raths; ruins of abbeys and churches, chiefly built by descendants of the English invaders under Henry II.; and many ancient castles or square towers.

Cork, a city and parliamentary borough of Ireland, capital of County Cork, and a county in itself, on the Lee, 11 miles above its mouth, and 166 SW. of Dublin by rail. Standing in the centre of a picturesque valley, it is built in part on an island, or group of islands, formerly a swamp, which the word *Cork*, *Corcock*, or *Corraig* implies; in part, on the north and south slopes of the river-banks. The houses are generally of old red sandstone. Nine bridges cross the river to the central islands. There is a spacious public park of about 400 acres, the chief use of which is as a racecourse, and a walk known as the Mardyke, above a mile long, lined by noble elms, on the west of the city. There is also a beautiful public cemetery. Cork has a pleasant picturesqueness from its uneven ground, irregular streets, intersecting river, and overhanging heights. The chief buildings are St Anne Shandon's Church, with a tower 170 feet high; the Protestant Cathedral, Early English in style, erected since 1865 at a cost of £100,000; several Catholic churches; 4 monasteries; 2 nunneries; the bishop's palace; the Queen's College, a fine Tudor-Gothic quadrangular building, opened in 1849; the Schools of Science and Art, erected mainly through the munificence of a citizen, Mr W. H. Crawford. The banks of the Lee above and below Cork are richly planted, and studded with villas. The Lee in both branches is navigable to about a mile above the city, and a large sum has been expended on the improvement of the navigation by the harbour commissioners. The extent of the quays is now above 4 miles, and ships of 2000 tons reach them. Cork harbour, noted for its size and safety, is a basin of 10 sq. m., formed by the estuary of the Lee. It could contain the whole British navy, and has been the main source of the rise and progress of the city. It is the port of call for the transatlantic steamers plying between Liverpool and New York, the vessels of seven different lines touching each week to embark or discharge mails and passengers. The estuary contains several large isles, rising abruptly and high above the water, with narrow channels between them. The entrance is by a channel two miles by one, defended by batteries. Carlisle Fort on the east side, and Camden Fort on the west, while Spike Island, now called Fort Westmoreland, commands the entrance. In these forts some of the heaviest ordnance in the kingdom may be found, Camden in addition possessing a torpedo and submarine battery of immense destructive power. Spike Island has ceased to be a convict establishment, and is used now as a military dépôt. Adjoining the island of Haulbowline, on which are erected extensive government stores, is a large government dock, where vessels of the British fleet may be repaired. On the shores of the estuary are the towns of Passage and Queenstown, formerly Cove of Cork. Cork harbour is much frequented by wind-bound ships and ships waiting orders. In 1880-85 from 2880 to 2500 vessels, with a total tonnage of 735,000 to 680,000 tons, annually entered the port; and from 2750 to

2400, of from 685,000 to 682,000 tons, annually cleared. The chief manufactures are leather, iron, gloves, gingham, friezes, flour, malt liquors, and whisky. The chief exports are grain, provisions, butter, live-stock, leather, and tweeds, valued at several millions sterling yearly. Pop. (1871) 78,642; (1881) 80,124; parliamentary borough, 104,496, of whom five-sixths are Roman Catholics. Cork returns two members to parliament.—Cork grew up around an abbey founded in 600 by St Finbar. The Danes in the 9th century built the city walls. Dermot MaccCarthy, king of Cork or Desmond, surrendered it to Henry II. in 1172. Cromwell besieged and took it in 1649, and Marlborough in 1690. James II. landed at Cork in 1688. In Cork, William Penn, the founder of Pennsylvania, became a Quaker. There is a statue of Father Mathew (q.v.), who laboured here many years. See Miss Cusack's *History of the City and County of Cork* (Dublin, 1875). For the Earls of Cork, see BOYLE.

Corkwing (*Crenilabrus melops*), a species of Wrasse (q.v.).

Corleone, a town of Sicily, 21 miles S. of Palermo. Pop. (1881) 15,441.

Corm (Gr. *kormos*, 'a stump')—sometimes called a *solid bulb*—the short and bulb-like subterranean stem of many monocotyledonous plants, e.g. crocus, gladiolus, tuberose, and arising through the annual storing of starch to be consumed by the next year's bud and flower. In functions, as in general appearance, the corm resembles the Bulb (q.v.); a vertical section, however, shows that while in each we have indeed a stem and leaves, the thickening is confined in the former case to the stem, in the latter to the leaves. Transitional forms occur, indeed, in most bulbs; the thickened leaves arise from a more or less thickened and shortened—i.e. corm-like—base. While a section of a corm shows the origin of its usually membranous leaves, and many corms produce new subterranean buds in the axils of their leaves, in either case they arise on the upper surface or sides of the parent corm, and there thicken as new corms. When borne on the upper surface, the new corms then gradually approach the surface of the ground as in crocus.

Cormorant (Gr. *Phalacrocorax*, 'bald-headed raven'), a genus of web-footed birds in the order Steganopodes, beside pelicans, solan-geese, and frigate-birds. They are familiar birds, frequenting islands in most parts of the world. They vary

Cormorant.

greatly in size, but have the following characters in common. The head is relatively small, and is naked behind the eyes and at the root of the beak. At the breeding season some forms exhibit a crest

and wattles. There is a dilatable membrane beneath the lower jaw, showing incipiently what becomes exaggerated in the pelicans. The bill is moderately long, straight, rounded above, and strongly hooked at the end; the nostrils are linear and inconspicuous. The neck is long, snake-like, and naked on the throat. The wings are of moderate length; the tail is rather short and rounded, but with stiff feathers, which are used as aids in progression. The unfeathered lower leg is very short; all the toes are united in a web; the middle claw is serrated and apparently used in trimming the plumage.

The numerous species live on the shores of islands, or sometimes inland by rivers—e.g. the Danube—and lakes. They feed exclusively on fishes, and are proverbial for their voracity. They do not dive when in flight, but from the surface of the water. The smaller of the two British species has been caught in a crab-pot at a depth of 120 feet. When the prey is inconveniently seized, it is often tossed in the air and more adroitly recaptured. Eels are said to form a favourite prey. Their haunts are often peculiarly dirty. The nests are usually built of seaweed, and are strong though rude; they are sometimes found on mangrove and other trees. The egg is bluish-green, but the colour is much obscured by thick incrustations of lime. When attacked, the larger species, at any rate, fight vigorously and to purpose. The flesh is dark and fishy, but that of the young birds of some species is said to be eatable.

The Common British Cormorant (*P. carbo*) is an almost cosmopolitan bird about 3 feet long, for the most part of a blackish-green metallic colour, with brownish feathers on the shoulder region. When in full breeding plumage it has a crest on the head, white plumes on the throat, and a white patch on the lower flanks. The bill is black, the face yellow, the feet also black. It was formerly trained in England, as still in China, for fishing purposes. At first a ring is put round its neck to keep the bird from swallowing the fish it catches, but it soon learns to bring its prey to its master, being afterwards allowed to fish on its own account. The smaller species (*P. cristatus* or *granulus*) found on our coasts has a more decided green colour. The Dwarf Cormorant (*P. pygmaeus*), from South-eastern Europe, North Africa, Southern Asia, and the Florida Shag (*P. floridanus*) are other well-known species. Along with the genus *Urile*, the cormorants form a family (Phalacrocoracidae) including about three dozen species.

Corn, a general term for the seeds of cereal plants, thus including all the kinds of grain which form the food of men or horses. But it has also a specific sense, and denotes in any country that grain which furnishes the prevalent bread-stuff of the people. Thus, in England, corn generally means *wheat*; in the United States, *maize*; and in Scotland, *oats*. The word not only occurs in all the Teutonic tongues, but is seen also in Lat. *granum*, and Russian *zerno*. See CEREALS, and special article WHEAT, &c. See CORNS for a different word.

Cornaceæ, the cornel or dogwood order, are calycifloral dicotyledons, nearly allied to Umbellifere, containing about eighty species, mostly trees and shrubs, chiefly natives of the north temperate zone. The fruits of some are eatable; the bark and leaves of some are medicinal; some are valued as ornamental plants. See CORNEL, DOGWOOD, ACURBA.

Cornaro, the name of a Venetian noble family, of which the most illustrious members were: (1) Caterina (1454–1510), married King James II. of Cyprus in 1472, after whose early death she was kept in mild imprisonment by the Venetians until

1489, when she set up a kind of court for poets and scholars at Assolo, near Bassano.—(2) Luigi, born 1467, an instructive example of temperance. Delicate by constitution, at forty he found his health so much impaired by his intemperance that an immediate change of life was absolutely necessary. He at once adopted strict rules of temperance both in meat and drink, by which means he prolonged a cheerful old age almost to a hundred years, dying in 1566. At eighty-three he published his famous *Discorsi della Vita Sobria* (Padua, 1558), which was translated into most European languages (Eng. 1779).

Cornbrash, a member of the Lower Oolites. See OOLITE.

Corn-cockle (*Agrostemma Githago*), a tall beautiful caryophyllaceous weed, well known on account of its large purple flowers. It is often so common in cornfields as to be mischievous, especially on the Continent, and this not only because of its rankness and abundance, but also because of the deleterious nature of its seeds, which are injurious to man and poisonous to most domestic animals, and which sometimes require to be separated from the grain by a special kind of sieve.

Corn-crake (*Crex pratensis*), one of the true rails, in the old order of Grallatores, whose cry at least is very familiar in Britain. The bird itself is seldom seen; it is about a foot in length, and has colours varying from brownish-gray to red. The bill is shorter than the head, and slightly bent, the tail is very short, the legs are long and powerful. As a summer visitor to Britain, coming in May and leaving in autumn, the bird is well known by the harsh cry of the male, which is sometimes imitated for decoy purposes by running the thumb-nail along the teeth of a small comb. The cry is

Corn-crake (*Crex pratensis*).

mostly uttered in the evening and throughout the night, and is much less frequent after the young are hatched. Unlike the nearly related water-rails, the corn-crake frequents dry corn and hay fields. It can, however, swim well on occasion. Its running powers are very great, but it flies rather heavily. It is very prone to trust to concealing itself rather than to flight. The females are very faithful to the young birds, which are covered with black down when hatched. The species is widely distributed in Northern Europe and Central Asia, but its headquarters are in Africa. The flesh is very good eating. See RAIL.

Cor'nea, one of the coats of the eye; so called from its resemblance to horn (Lat. *cornu*). See EYE.

Corneille, PIERRE, the greatest tragic dramatist of France, and the forerunner of Molière in genuine comedy, was born at Rouen on June 6,

1606. The son of a legal official, he was trained for the bar, and for some time tried with but slight success to obtain a practice in his birthplace. In 1629 he removed to Paris, where his comedy *Mélite*, which had already been performed at Rouen, proved so successful as to be run at the same time in two theatres, the Marais and the Hôtel de Bourgogne. It was followed by *Clitandre*, *La Veuve*, *La Galerie du Palais*, *La Suivante*, and *La Place Royale*. In these early pieces intricate and extravagant plots are handled with considerable ingenuity, but the writer's poetic genius only flashes out in occasional verses. For some time Corneille was numbered among Richelieu's 'five poets,' the others being Rotrou, Colletet, Bois-Robert, and L'Etoile. These writers were engaged to compose plays on lines laid down by the cardinal. Each of the five wrote an act, which was then criticised, altered, and paid for by their employer; among the pieces thus produced being *Les Turleries*, *L'Aveugle de Smyrne*, and *La Grande Pastorale*. Corneille, however, was too independent to retain Richelieu's favour, and his dismissal followed at once on his proposing to alter a plot of the cardinal's devising. *Médée*, a tragedy which appeared in 1635, showed a marked advance on his earlier works, both in dramatic power and in style; and in 1636 the *Cid*, his most famous if not his best play, took Paris by storm. Richelieu ordered his literary retainers to write down the piece, and Scudéry called on the Academy to vindicate French letters in the eyes of Europe by passing formal censure on Corneille. The Academy, which had lately been founded by Richelieu, thereupon issued a hostile *examen* of the play; but adverse criticism was powerless against the general enthusiasm, and the phrase *beau comme le Cid* passed into the language. The result of the struggle between the minister and the dramatist is happily summed up in Boileau's famous couplet:

En vain contre le *Cid* un ministre se ligue,
Tout Paris pour Chimène a les yeux de Rodrigue.

The story of the play was taken from *Las Mocedades del Cid*, a Spanish work by Guillem de Castro (q.v.), but Corneille's treatment of the subject was thoroughly original. With the appearance of the *Cid* the poetic drama took possession of a stage hitherto occupied by broad and shapeless farces, wooden imitations of Seneca, and the extravagant and off-hand pieces of Hardy. The graceful and heroic figures of the lovers, Rodrigue and Chimène, the nobility of the sentiments, the power and harmony of the verse, justify the enthusiasm which the play excited. It may not be its author's greatest effort, but there is a charm in the spirit of youthful ardour and tenderness which animates it such as is hardly to be felt again in Corneille's work, until we come to the exquisite lyric love-scene which he contributed in his old age to the opera of *Psyché*.

The *Cid* was followed in 1639 by *Horace*, a play which was founded on the story of the Horatii and Curiatii as told by Livy, and which contains, in the *tirade* spoken before her death by Camille, the most magnificent burst of invective in the French classical drama. *Cinna* appeared in 1639; *Polyeucte*, one of Corneille's noblest tragedies, in 1640; and *La Mort de Pompée* in 1641. *Le Menteur*, which was produced in 1642, entitles Corneille to be called the father of French comedy as well as of French tragedy. The play is a masterpiece. The character of Dorante, the liar, is drawn with admirable humour and insight, and the style, at once easy, graceful, and pointed, reaches a level of excellence which Molière did not surpass in his earlier works. *Théodore* was brought out in 1645, and *Rodogune*, perhaps the most impressive and

thrilling of Corneille's tragedies, in 1646. Between 1647—when he was made an academicien—and 1653 Corneille produced *Héraclius*, *Don Sanche d'Aragon* (an imitation of Lope de Vega's *Palacio Confuso*), *Andromède*, *Nicomède*, and *Pertharite*. These pieces, of which the last named was damned, show a decline in dramatic and poetic power. After the failure of *Pertharite* in 1653, Corneille ceased for a time to write plays, and occupied himself with making a verse translation of the *Imitatio Christi*. He returned to the stage in 1659 with *Œdipe*, which had considerable success, and which was followed by *La Toison d'Or*, *Sertorius*, *Sophonisbe*, *Othon*, *Agésilas*, *Attila*, and *Tite et Bérénice* (1670). In 1671 he joined Molière and Quinault in writing the opera of *Psyché*, and the loveliest verses which he ever penned are to be found in the scene between *Psyché* and Cupid (act iii. scene 3). His last works were *Pulchérie* (1672) and *Suréna* (1674).

His work did not bring him wealth, for he never received more than 200 louis for a piece. His private fortune was not large, and the pension which was granted him was not regularly paid. After his marriage in 1640 he lived habitually in Rouen until 1662, when he settled in Paris. His domestic life seems to have been a happy one. He and his brother Thomas married two sisters, and dwelt for a long time in contiguous houses. During his later years he had to compete with Racine, an inferior poet but a more dexterous playwright, and one who could cater more shrewdly for the public taste. The veteran dramatist spoke contemptuously of his rival's 'sighs and flames,' but his popularity waned before that of the younger writer, whose cause was espoused by Boileau and the king. Corneille died in Paris in the Rue d'Argenteuil on October 1, 1684.

Corneille and Racine are the chief dramatists of the classical school which held command of the French tragic stage from the middle of the 16th century down to the Romantic movement of 1830. The works of this school were modelled on the plays of Seneca—that is to say, on plays cast in the mould of Greek tragedy, but having even less action and more diffuse moralising. The writer who adopts this form of drama is bound down by a set of rigid rules which allow him to present only a few idealised personages in certain stereotyped situations. He cannot exhibit the development of character and the interaction of human passions. He is almost denied the use of incident, and the slow progress of his play to its climax is mainly brought about through the agency of messengers and confidants. Before Corneille the classic school had failed to produce a single good acting play; its adherents, nevertheless, succeeded in diverting him from the path on which he had entered when he produced the *Cid*, and in thereby cramping his rich and vigorous genius. 'Corneille,' says Mr Walter Pollock, 'was one of the first to make a move in the direction of the romantic drama, and wanted nothing but courage and self-sacrifice to carry out his intention.' (See his admirable articles on Victor Hugo and Romanticism in *French Poets*, 1879). Unfortunately, instead of disregarding the academic criticism of his day, Corneille turned from Spain to a 'Castilian Rome,' remote from the world of romance, and set himself to compose plays of so severe and uneventful a type that he failed, save in one or two cases, to invest them with a strong sustained interest. In reading these plays we yield alternately to admiration and fatigue. The characters have a simplicity and grandeur which recall the work of the sculptor, but they have also something of its immobility. We can grasp them at once; they are not developed in the course of the drama. Corneille's heroes bear their fate with an inflexible

self-reliance which seems more than human, and therefore moves us the less. His heroines, his 'adorable furies,' resemble one another closely. 'Their love,' says Sainte-Beuve, 'springs from the head rather than the heart. We feel that Corneille knew little of women.' Where he excels his rivals is in the grandeur of his morality, in the eloquence and passion of certain scenes and speeches, in the splendid flashes of poetry with which he illumines the pale world of classic tragedy, in the power and music of his verse. Victor Hugo alone has made the Alexandrine move with the same swelling harmony and variety of cadence. The monotony which so often weighs on Corneille's readers was not due to any coldness or narrowness inherent in his genius. To be convinced of this it is enough to recall the brilliant comedy of the *Menteur*, the martial stir and glowing passion of the *Cid*, the lyric grace and chastened ardour of the central love-scene in *Psyché*. But his powers were in a measure misdirected. His place in literature must always be a very high one; but readers—other than French readers, at least—can hardly doubt that it would have been still higher had he been free to select and develop his characters at will, to exercise his humorous faculty and give full scope to his tragic powers in the fields of romantic drama.

See Guizot's *Corneille et son Temps* (1852; Eng. trans. 1857); Jules Taschereau's *Histoire de la Vie et des Ouvrages de P. Corneille* (1828; new ed. 1855); Sainte-Beuve's *Portraits Littéraires* (tome i.) and *Port Royal* (tome i.); Bouquet, *Points obscurs de la Vie de Corneille* (1888); Trollope, *Corneille and Racine* (Lond. 1881). The best editions are those by Lefèvre (12 vols. 1854), and Marty-Laveaux (12 vols. 1862-67). See M. E. Picot's *Bibliographie Cornélienne* (1875).

Corneille, THOMAS, younger brother of the great Corneille, was born at Rouen on August 20, 1625. He was a dramatist of considerable merit, was made a member of the Academy in 1685, and died at Andelys on December 17, 1709. His tragedies, *Camilla*, *Loüdicé*, *Pyrrhus*, *Bérénice*, *Timocrate*, *Ariane*, *Bradamante*, &c., are in general superior to his comedies. He also wrote a verse-translation of Ovid's *Metamorphoses*.

Cornel, or CORNELIAN CHERRY (*Cornus mas*), the *Cornus* of the ancients, a small tree of the order Cornaceæ, is a native of the middle and south of Europe, and of great part of Asia. It is not found wild in Britain, although it is common in shrubberies, and was formerly much cultivated as a fruit-tree, as it still is in Germany and other parts of Europe. It has oval leaves, and small yellow heads of flowers, which appear before the leaves in spring, and which are much frequented by bees. The fruit is oblong, a little larger than a sloe, shining, red, or rarely yellow or white. It is late in ripening, and until quite ripe is very austere; but when perfectly mellow has an agreeable vinous acid taste; it is also made into a preserve, or gathered unripe and pickled like olives. It was formerly also fermented for a beverage. In Turkey it is much used in making sherbet. The wood of the cornel is extremely hard and tough, and was used by the ancient Greeks for lance-shafts; it is still valued by joiners, turners, and instrument-makers.—Dwarf Cornel (*C. suecica*), a native of mountain-pastures and bogs throughout the north of Europe and in Britain, is a herb about 6 inches high, with its umbels surrounded by four white bracts. The small sweetish red fruit is tonic, and is said to increase the appetite, whence the Gaelic name *Plant of Gluttony*. Dogwood (q.v.) belongs to the same genus.

Cornelia, the mother of the Gracchi (q.v.).

Cornelian. See CARNELIAN.

Cornelisz, LUCAS, a Dutch subject and portrait-painter, was born at Leyden in 1495, the son

of Cornelis Engelbrechtsen, the master of Lucas van Leyden. He was instructed in art by his father, but found little patronage in his own country, and was obliged, for the support of his large family, to act as a cook, whence his usual sobriquet of *Kok* ('the cook'). He visited England, probably in 1527, and was appointed by Henry VIII. royal painter. There is ground for believing that, after remaining some five years in England, Cornelisz passed to Italy, and between 1535-47 was employed by the court of Ferrara. He is stated to have died in 1552. Several of his works are in England.

Cornellius Nepos. See NEPOS.

Cornelius, PETER VON, one of the first masters of the modern German school of painting, was born at Düsseldorf, 23d September 1783, and studied in the academy of his native town. When only nineteen years of age, he painted some remarkable frescoes for the old church of Neuss. Four years later he gave still more unmistakable proofs of a creative fancy in his illustrations of Goethe's *Faust* and the *Nibelungen Lied*. In 1811 he went to Rome, and joined the group of Veit, Schadow, and other Germans who were there at work, Overbeck being his chosen friend. This journey exercised a profound influence on the whole of his future career. The great importance of the early masters became ever clearer to him as he studied their choicest productions. While at Rome he aided in the decoration of the Casa Bartoldi, and gained wide reputation by two cartoons, 'Joseph's Interpretation of the Dream' and 'Joseph's Recognition of his Brethren.' From Rome he passed to Düsseldorf, where he became director of the academy, which he remodelled; in 1819 he was called to Munich, and entered the service of the then crown-prince of Bavaria. Here he remained till 1841, and executed those grand works on which his fame mainly rests, and which may be divided into two classes, Pagan and Christian, the former of which comprises the large frescoes in the saloon of the Glyptothek, all illustrating stories of the Greek gods and heroes; while the latter, or Christian series, begun after the completion of the former in 1830, consists of frescoes of New Testament scenes, extending from the 'Incar-nation' to the 'Judgment,' and decorates the 'Ludwig's Church' in Munich, which was built for the purpose of affording scope for the genius of Cornelius. The 'Judgment' is the largest fresco in the world, larger even than Michael Angelo's 'Judgment' in the Sistine Chapel. In 1841 Cornelius was invited by the king of Prussia to Berlin, where he was appointed director of the Berlin Academy. Among his productions in the Prussian capital are the frescoes for the Campo Santo, or royal burial-place, where his 'Four Riders of the Apocalypse' display an impetuous and daring power which he had not hitherto evinced. Opinion is divided regarding the merits of Cornelius. By his own countrymen he is much admired; and certainly the importance of the impetus which he gave to mural decoration in Germany cannot be overestimated. French critics, on the other hand, regard him as more a thinker than an artist. He is admitted to have been a profoundly creative genius, but without mastery in manipulation or great power as a colourist. He formed, however, a school, from which have gone forth many illustrious pupils; but he lived to see it losing hold on public sympathy. A series of his cartoons is preserved in the National Gallery, Berlin, and his works have been reproduced by Amster, Schoefer, Eberle, and the best German engravers. He died in Berlin, 6th March 1867. See his *Life* by Förster (2 vols. Berlin, 1874).

Cornell University, named from its founder, Ezra Cornell (1807-74), is pleasantly situated on the outskirts of the town of Ithaca, New York, and was opened in 1868 on a thoroughly unsectarian basis. It has numerous well-appointed buildings, including Sage College, for women; in 1888 the number of instructors was 51, and of students 1022, including 106 women. Students may provide for their support by labour on the farm, or in the machine-shops and printing establishment attached; and by the terms of its charter the university must educate, free of all fees, one student annually from each of the 128 assembly districts of the state of New York, besides providing instruction in 'agriculture and the mechanic arts,' in return for the income derived from the sale of 989,000 acres of public lands, which was transferred to it by the state. The endowment funds amount to nearly \$2,500,000. Besides three general courses of four years each, in arts, literature, and science, the university provides special instruction in agriculture, architecture, chemistry, and physics, civil engineering, history, and political science; ancient, European, and oriental languages; mathematics, mechanic arts, military science and tactics, natural history, philosophy and letters, and (since 1888) journalism.

Cornet (Ital. *cornetto*, Fr. *coronet à piston*), a brass treble wind-instrument, with a cup mouth-piece, is a comparatively modern modification of the Trumpet (q.v.). The tube, which is more tapered than in the trumpet, is less so than in the Bugle (q.v.), giving the cornet a tone intermediate between these, and more in harmony with other brass instruments of the trombone and saxhorn kind. It has the usual open notes, C (below the treble stave), G, C, E (stave), G, Bb, E (above the stave). It has also four higher notes, D, E, F, G, and a fundamental note, C (octave below the stave), but they are almost never used. To provide the connecting notes and half notes of the scale, it has three slides (1, 2, 3 in the fig.), the first, lengthening the tube to the extent of one tone; the second, a semitone; the third, three semitones. In playing, the air is diverted through these slides by means of three valves or pistons, which are depressed by the fingers of the performer, singly or in combination.

Although the cornet, from its recent invention, has not a place in classical music, it is sometimes used to play trumpet parts; and in modern orchestral music, it is an indispensable and popular solo

Cornet.

instrument. In military reed and brass bands it is a solo and leading instrument respectively.

Originally the cornet or *cornopoean*, as it was then called, was provided with 'crooks' (pieces of tube to insert between the instrument and the mouth-piece), to alter the pitch, which is naturally Bb, to A, Ab, G, and others, but it is now only used in Bb and A. Smaller cornets in Eb and Db are sometimes used in military brass bands. The cornet-stop in the organ is named after an obsolete wind-instrument of the oboe species.

Cornet (Ital. *cornetta*, 'a small flag') was, until 1871, the lowest grade of commissioned officer in the cavalry, equivalent to *ensign* in the infantry, one of his duties being to bear the standard, which, however, is only carried by heavy cavalry regiments in the British army. With the lieutenant he assisted the captain in the daily duties connected with the troop to which he belonged. Before the abolition of purchase in 1871 a cornet's commission used to cost £450; but much larger sums were habitually paid in celebrated or fashionable corps. The pay was 8s. per day, with 1s. or 1s. 6d. extra for field allowance. In 1871 cornets were abolished, sub-lieutenants (who are merely probationary lieutenants) being substituted.

Corneto, a picturesque, medieval-looking town of Central Italy, 12 miles N. of Civita Vecchia by rail, 3 miles from the Mediterranean. Pop. 6175. Corneto rose out of the ruins of the Etruscan city of *Tarquini*, whose remains, within a mile and a half of Corneto, are amongst the most important for the student of Etruscan history. The painted tombs, of which some twenty are specially interesting, were known in the 18th century; but it is mainly since 1842 that they have been examined; valuable new discoveries were made during excavations in 1881-82. See ETRURIA.

Corn-flour is the name applied to the finely ground flour of Maize (q.v.) or Indian corn.

Corn-flower (see CENTAUREA) is a well-known composite weed of cornfields, universally known

Corn-flower, or Blue-bottle (*Centaurea cyanus*).

and admired for the beauty of its wreath-like circle of outer barren florets, and the splendid deep azure of their hue. It was formerly of some little medicinal repute, and its blue flowers were used in domestic dyeing; from early times, too, it has been used for decoration in wreaths and garlands. This use became specially prominent in Germany after 1870, on account of its being the Emperor William's favourite flower.

Cornice. In classical architecture the cornice is the uppermost member of the entablature, surmounting the frieze. Each of the orders has its peculiar cornice; but these, with their relation to the other portions of the entablature, will be better understood when explained in conjunction with that term (see ENTABLATURE). In the Gothic styles the form of the cornice varies greatly. In Provence and countries where Roman work abounded, the classic cornice was closely imitated (see ROMANESQUE ARCHITECTURE). In other

districts a row of corbels, carved in the grotesque Teutonic spirit, and bearing the parapet, forms the cornice. A series of small arches frequently rests on the corbels. This is the prominent style of cornice in all Rhenish and Lombardic structures.

Corbel Table.

In Early Gothic the small arches become ornamental—taking the form of trefoils with moulded edges, and the corbels become less uncouth. The decorated and perpendicular cornices are chiefly horizontal mouldings, with flowers or heads inserted

Cornice:
Eynsham Church, Oxon, circa 1450.

as enrichments. The term cornice is also applied to the plaster mouldings seen round the ceiling of rooms at its junction with the walls.

Corniche. See RIVIERA.

Corniferous Period, name given in North America to the lowest division of Devonian time. It embraces the Corniferous epoch, the Schoharie epoch, and the Canda-galli epoch. The name *corniferous* (Lat. *cornu*, 'horn,' *fero*, 'I bear') has reference to the common occurrence in the limestones of a quartzose mineral called *hornstone*.

Corn Insects. While numerous insects are of great importance in carrying the fertilising pollen from one flower to another, and others are in themselves of direct use to man, there remains a vast crowd of more or less injurious forms. Of these some attack man and domestic mammals, others do damage quite as effectively by injuring fruit and forest trees, vegetables and crops. A convenient account of these injurious insects will be found in Miss E. A. Ormerod's *Manual of Injurious Insects and Methods of Prevention*, and fuller details may be gathered from other works mentioned below. It is here proposed simply to give a brief list of the more important insects injurious to corn crops. First then (following Leunis), we may notice some of those which are tolerably wide in their destructiveness: (1) *Zabrus gibbus* (Coleoptera, Carabidae), a dark bronzed beetle, abundant in Central Europe, less common in England, ravaging wheat-fields, the adults devouring the grain, the larvae the leaves. (2) *Melolontha vulgaris*, Cockchafer (q.v.). (3) *Rhizotrogus solstitialis*, Midsummer Chafer, a beetle nearly related to the last, of generally similar

Corn Aphid:
a, natural size.

habit, the larvae sometimes injuring the seed. (4) *Agriotes lineatus*, &c. (Coleoptera, Elateridae), Skip-jacks, Click-beetles, Wireworms (q.v.), injuring root, grain, and fodder crops. (5) *Chrysomela cerialis*, in the same genus as the Colorado Beetle (q.v.), common in Europe on grasses, and occasionally on cereals. (6) *Cephus pygmaeus*, Corn Saw-fly (Hymenoptera, 'wood-wasps'), a long, thin-bodied, minute insect, of a brilliant black colour, the larvae injurious to wheat and rye, feeding on the inside of the stalk, and eventually cutting it through near the ground. (7) *Agrotis tritici*, &c., 'cut-worms' (Lepidoptera, Noctuidae), common moths whose caterpillars feed upon the roots of grasses and other crops. *Neuronia popularis* is a similar form also injurious to grasses and the like. (8) *Cecidomyia destructor*, or Hessian Fly (q.v.). (9) *Diplosis tritici* and *aurantiaca*, allied to the last, infesting wheat, rye, &c. (10) *Anthomyia coarctata* (Diptera, Muscidae), a fly whose eggs are laid in seed, which the larvae devour in spring. (11) *Pachytylus* or *Oedipoda migratorius* and *cinerascens* (Orthoptera, Acrididae), locust-like insects, which, like some other members of the order, do great damage when they appear in hosts. *Aceridium egyptium* and *Caloptenus italicus* are allied forms not infrequently doing great damage to vegetation (see CRICKET and LOCUST).

Wheat crops are specially liable to be attacked by the following insects: (12) *Chlorops taniopus* and *lineatus* (Diptera, Muscidae), flies which deposit their eggs on the ears of corn. The development of the maggots checks the growth, and causes the ears to abort. In Britain barley is oftenest attacked by *C. taniopus*, which has received the

Corn-fly (*Chlorops taniopus*):

a, a portion of a culm or stem of wheat with a swollen joint, caused by larva of corn-fly; b, larva; c, pupa; d, fly, natural size; e, fly, magnified.

Corn Ground Beetle:

1, larva, magnified; 2, natural size of larva; 3, perfect insect, female, slightly magnified; 4, a cell containing pupa; 5, a burrow.

name of Gout-fly from the swollen distortions which appear at the joints of infected plants. Towards the end of summer the insects leave the ears as two-winged flies, about the eighth of an inch long, thick and stumpy in shape, yellow, with

three black stripes along the back between the wings, and the abdomen of a greenish-black, with black cross-bands. *C. lineata* often does great

Corn Saw-fly:

a, maggot, natural size; b, maggot, magnified; c, the maggot in its ear in the stem of the corn; d, female insect, magnified; e, female insect, natural size.

damage to wheat crops. (13) *Cecidomyia tritici*, the Wheat-midge or Red Maggot (Diptera, Cecidomyiidae), in the same genus as the Hessian Fly (q.v.), deposits its eggs in the young wheat ears, and sometimes does much damage. *Lasioptryx obfusca* is another Wheat-midge of similar appearance and habit. (14) *Aphis cerealis*, Grain Aphis (Hemiptera, Aphidae), sucks the sap from wheat and other cereals, and sometimes does much damage (see APHIS). (15) *Thrips cerealium*, Corn-thrips (Thysanoptera, Thripidae), a very minute, hardly distinguishable insect, which sucks the sap from wheat ears and causes the seed to shrivel. (16) *Tipula olivacea*, or Daddy Long-legs (q.v.), or Crane-fly, often does great damage to corn and other crops.

Oats, like barley, are very often damaged by some of the above, and especially by *Chlorops tenuipus* and *C. frit*, *Aphis cerealis* and *A. avenae*, and *Thrips cerealis*. Rye is also subject to these and some other devastating insects.

Of a somewhat different habit from the above is *Tinea granella*, the Corn-moth (Lepidoptera, Tineidae), in the same genus as the Clothes-moths. This form lays its very small eggs among stored grain or on the sheaves. The larvæ, or Corn-worms, appear among the grain on the granary floor, and when care is not taken to keep things clean and the grain well shovelled, often does much damage. From its voracity it is known as the wolf. It spins a web round several grains, and gradually devours them. Another of the granary pests is *Calandra granaria*, the Corn-weevil or brown Corn-worm (Coleoptera, Curculionidae), a small reddish-black insect, not quite two lines long, and without wings. It seems to have come to Europe from the East, but is now common in the southern regions. The female lays an egg in each of a number of grains, the larvæ soon develop, and a second brood is produced the same summer. The most successful method of arresting the mischief is said to be that of leaving a small heap of corn undisturbed, while the great mass is well shovelled. The weevils shift to the unstirred heap, and may then be destroyed. See WEEVIL.

For the remedies used, Miss Ormerod's work should be consulted. See also *Bulletins of U.S. Entomological Commission*; *Journal of Royal Agricultural Society*; John Curtis, *Farm Insects*; Kaltenbach, *Die Pflanzenfeinde aus der Classe der Insekten* (1874); Taschenberg, *Praktische Insekten-kunde* (1880); Schmid-Goebel, *Die Schädlichen und nützlichen Insekten in Forst, Feld, und Garten* (1881).

Corn Laws, the name popularly given to certain statutory enactments which had for their object a restriction of the trade in grain. The English corn laws date as far back as the year 1360, in the reign of Edward III. Before this

period, there seems to have been a general rule carried into effect by the crown against the exportation of any grain; and the Act of 1360 enacts the prohibition, but at the same time excepts certain places which the king may appoint by license. An Act of 1436 permitted exportation when the price of wheat did not exceed 6s. 8d. per quarter. Hitherto, there seem to have been no prohibitions against importation; but in 1463 an act was passed prohibiting it so long as the price at home was below the 6s. 8d. at which there was free exportation. The next change was in the reign of Henry VIII., when an Act of 1534 prohibited all exportation except by license specially granted under the great seal. This act was not found to work well; and twenty years later the previous arrangement was adopted of allowing exportation when the price stood below a certain point. In 1562 exportation was permitted when the price was under 10s. a quarter. Export duties of varying amounts were imposed from 1570 to 1689, when they were altogether abolished. The subsequent legislation for some time merely changed the price at which exportation might begin, generally enlarging it. After the Restoration, the policy of increasing the duties on importation, for the protection of agriculture and the landed interest at home, begins to be perceptible. At the same time the effect of that event on the relations of Scotland and England towards each other forms a curious illustration of such fiscal regulations. Under the Protectorate they were one country, with free intercommunion of trading privileges. Scotland was increasing in wealth under this arrangement; but the countries were separated by the restoration of Charles II., and became the same to each other as foreign nations. The English duties restricted the importation of grain from Scotland; and in 1663 the Scotch parliament, in retaliation, laid heavy duties on the importation of English and all other foreign grain. Had not the union of 1707 made the two countries one again, England and Scotland would probably have continued a corn-law contest against each other, as was the case with the French provinces under the old regime.

The agricultural interest continuing powerfully to control this department of legislation, an act was passed in 1670 for virtually prohibiting importation into England until the home price had reached 53s. 4d., and laying a heavy duty on it above that point. This law had, however, little effect in favour of the landed interest, from the circumstance that then, and for long afterwards, Britain was an exporting, not an importing country—that is to say, it generally produced more corn than its population required. A new device was adopted at the Revolution of 1689, a bounty being awarded on exportation—i.e. a sum of 5s. was paid for every quarter of wheat sent abroad when the price fell below 48s., so that if the price in the foreign market would not induce people to export corn, the bounty, in addition to that price, might. For upwards of a century the numerous enactments in this department will be found to be a mere shifting, according to circumstances, of the incidence of the bounty on the one hand, and of the import duty on the other. In 1773 a permanent adjustment was supposed to be reached by Burke's act, which provided that the bounty should cease when the price reached 44s., prohibited exportation when the price was above that figure, and allowed importation at a nominal duty of 6d. at a price of 48s. In 1791, and during the wars of the French Revolution, further alterations in the corn laws favourable to the landed interest were effected. The bounties, however, were abolished in 1814. In 1815, after the conclusion of the wars, a law was

passed prohibiting importation of foreign corn when the price was below 80s. a quarter.

The principle of the sliding-scale which had been more or less followed in previous enactments was systematically carried out in the year subsequent to the great wars, in 1822, and particularly in 1828, when Wellington's sliding-scale was passed. The object of the device called the sliding-scale was to reduce the import duty as the price of grain increased, for the purpose of virtually prohibiting the importation when the price was low, and encouraging it when the price was high, so that at famine-prices grain might come in duty free. By the Act of 1828, the price of 62s. a quarter on wheat was taken as the turning-point. At that price the import duty was £1, 4s. 8d. For every shilling less in the price a shilling was added to the duty. When the price rose above this point a different gradation ruled, the duty decreasing by a larger ratio than the rise. Thus, when the price was 69s. the duty was 15s. 8d.; and when it rose to 73s. the duty sunk to its minimum of 1s. The effect of such fluctuation in rendering the trade a gambling one is obvious, and yet this was not acknowledged until it had been proved by a series of ruinous instances. Thus, an importer who, when the price of grain was 73s. a quarter, bought a cargo, if the price sunk 4s. before he could accomplish a sale, had not only to sell at that reduced price, but with a further reduction of 14s. 8d. a quarter paid as duty. What was still more important, the supplies to this country being so capricious and irregular, foreign countries did not grow corn habitually for the British market. In 1842 Sir Robert Peel tried a modification of the sliding-scale, which did not in the least degree mitigate the growing hostility to the corn laws.

The basis of this hostility to the corn laws was found in the population which had now grown up in the large towns. The effect of the industrial revolution connected with mechanical invention and the utilisation of steam had been to transform Great Britain from an agricultural into a manufacturing and commercial country. The new interests thus created were rapidly rising to supremacy. But the nation did not, till the very last, earnestly unite in calling for repeal. There was a powerful party who defended the corn laws, and represented, with great plausibility, that these restrictive statutes were for the public good. Their arguments might thus be summed up: (1) Protection was necessary, in order to keep certain poor lands in cultivation. (2) It was desirable to cultivate as much land as possible, in order to improve the country. (3) If improvement by that means were to cease, we should be dependent on foreigners for a large portion of the food of the people. (4) Such dependence would be fraught with immense danger; in the event of war, supplies might be stopped, or our ports might be blockaded, the result being famine, disease, and civil war. (5) The advantage gained by protection enabled the landed proprietors and their tenants to encourage manufactures and trade; so much so, that if the corn laws were abolished, half the country shopkeepers would be ruined; that would be followed by the stoppage of many of the mills and factories; large numbers of the working-classes would be thrown idle; disturbances would ensue; capital would be withdrawn; and what would happen then, the wisest could not foresee. Such arguments had great weight with the labouring-classes, the small-town shopkeepers, almost all the members of the learned professions, and an immense majority of both Houses of parliament. Those who endeavoured to represent the impolicy of a restricted trade in corn were generally set down as little better than mischief-makers. In the House

of Lords in 1839, Lord Melbourne, a Liberal premier, said, 'To leave the whole agricultural interest without protection, I declare before God that I think it the wildest and maddest scheme that has ever entered into the imagination of man to conceive.'

Meanwhile the ANTI-CORN-LAW LEAGUE concentrated the efforts of the free-trade party in Britain, and ultimately enabled them to carry the repeal of the corn laws, and to establish in practice the principle of free trade. In 1836 a number of philosophical radicals, among whom were Grote, Joseph Hume, and Roebuck, had formed an association for repealing the corn laws. In 1838 seven Manchester merchants formed an association of the same kind. The latter was soon joined by Cobden, who threw all his energy into the agitation, and secured for it also the eloquent advocacy of John Bright. Charles Villiers, who led their cause in the House of Commons, moved in February 1838 that the House resolve itself into a committee of inquiry on the corn laws. The motion was rejected by 342 to 195; and immediately the famous League was formed, with a central office at Manchester, its constitution dating from the 20th March 1839.

This was the beginning of a remarkable agitation, supported by lectures, verses, pamphlets, and popular oratory, which had a great influence on the economic and political education of the country. Large sums of money were raised, and a vast mass of popular literature bearing on the corn laws was diffused. In 1843 the League raised £50,000; in 1844, £100,000; in 1845, £250,000, for continuing the agitation. At a great meeting at Manchester in 1845, £60,000 were subscribed in an hour and a half.

The opposition to the corn laws steadily increased. Roused by the addresses of Mr Cobden, Mr Bright, and other leaders of the League, the people poured in petitions to parliament. The failure of the potato crop and the famine imminent in Ireland gave an overwhelming weight to the arguments of the League. At length the Conservative premier, Sir Robert Peel, became a convert to Free Trade (q.v.), and in 1846 carried a measure to put an end to the corn laws. By this act, the duty on corn was at once greatly reduced, and was to cease altogether in 1849, with the exception of a registration duty of 1s. a quarter, which terminated in 1869.

The repeal of the corn laws did not lead to a very great fall in the price of corn, nor did it result in the ruin of the agricultural interest. The vast expansion of industries, attended with a large increase of population and the growing demand for food, kept prices up to a tolerably high level. A markedly increased consumption of butcher-meat specially tended to enhance prices in that department and to raise the rent of land. With the development of American competition, about the year 1876, however, a new period set in. English agriculture *has* suffered severely, a fact which has largely contributed to the formation of a Fair-trade Party demanding among other things what they consider a moderate and reasonable protection for our landed and cultivating classes.

The pressure of American competition has also of late years led to the establishment of a corn-law system for the protection of agriculture in Germany. In 1879 protective duties on the importation of foreign grain were passed by the imperial parliament, and these have since been considerably increased. In France, trade in grain has long been subject to government regulation. During the course of the 19th century the duties on importation had been greatly reduced, but within the last few years things have followed the same course as in Germany. Slightly raised in 1881, the duties on grain were

increased five-fold in 1885. See BRIGHT, and COBDEN, and works there cited.

Corno, MONTE. See GRAN SASSO D'ITALIA.

Cornouaille, a district forming part of Brittany, included within the modern department of Finistère. It is one of the most barren and desolate parts of France; the chief town is Quimper. The identity of the name with Cornwall is obvious. See BRITTANY.

Corns (Lat. *cornu*, 'horn,' through the French) are small hard growths, resulting from an increase in the thickness of the cuticle or epidermis, which is generally caused by the irritation of some excessive pressure or friction on the part. They occur most commonly on the feet as a result of tight or ill-fitting shoes. Corns are either hard or soft; the structure of both classes is essentially the same. A *hard corn* begins as an ill-defined thickening of the epidermis at one point. As irritation continues, the excessive growth of epidermis increases, and the papillæ (see SKIN) beneath also enlarge, giving the deeper part of the growth a fibrous appearance, popularly described as the 'roots' of the corn. Pressure upon the sensitive nerves of these papillæ causes the usual pain of corns. Old corns often have a bursa or sac developed beneath them, which in part protects the underlying structures. Excessive irritation sometimes causes this bursa, or in its absence the connective tissue beneath a corn, to inflame and suppurate; and the little abscess thus formed, confined by the hardened epidermis, gives rise to intense suffering. In so-called *fibrous corns*, more allied to warts, the enlargement of the papillæ predominates, and the pain is greater than in ordinary hard corns. *Soft corns* occur between the toes, where the warmth and moisture promote early separation of the epidermis, and growth of the papillæ; they are therefore more vascular than the other forms, and often extremely painful.

The treatment of corns consists in the removal of all undue pressure or friction, either by removing the shoe altogether, or protecting the corn by surrounding it with a border of some soft material, as Amadou (q.v.) or soft leather; or the hardened cuticle may be pared or filed away, the central part most deeply. Within the last few years a new remedy has been introduced, now sold everywhere as a 'certain and painless cure for corns.' It consists of a solution of salicylic acid in collodion, one drachm to one ounce, with a small proportion of extract of Indian hemp. It is painted over the corn once or twice daily, and allowed to dry, with the effect of so softening the epidermis that, usually after six or eight applications, it can readily be peeled off with the aid of hot water. Soft corns should be freely dusted with oxide of zinc powder, and the affected toe isolated from its neighbours by means of medicated cotton-wool. If suppuration occur beneath a corn, the matter must be let out by a puncture, after the corn has been pared down. Those subject to corns should avoid patent leather boots, or even eschew leather altogether, and use 'molliscorium' or some other more porous substitute.

Corns affect horses as well as men. In the foot of the horse they occur in the angle between the bars and outer crust, and consist in a bruise of the sensitive secreting sole. Some forms of feet are especially subject to them. Corns constitute unsoundness; cause a short, careful, tripping gait; are the most frequent source of lameness amongst roadsters; abound in badly-shod horses, and usually occur in the inside heels of the fore-feet, these being more especially subjected to weight, and hence to pressure. The discoloured spot indicating the recent corn must be carefully cut into

with a fine drawing-knife; any serum or blood is thus allowed free vent. If the bruise has been extensive, a poultice will have the twofold effect of allaying irritation and relieving the sensitive parts by softening the hard unyielding horn. When the injury has been of some standing, and soft faulty horn is secreted, a drop of diluted nitric acid may be applied. On no account must the bars or outer crust be removed; they are required for bearing weight, which may be further kept off the injured part by the use of a bar-shoe. In horses subject to corns, harden the feet by putting on tips or slippers instead of full shoes, thus bringing the heels into contact with the ground; this will cause a rapid and strong growth of horn, not liable to be bruised.

Corn Salad, or LAMB'S LETTUCE (*Valerianella*), a genus of Valerianaceæ, humble annual weeds, of which some are used as spring salads, especially in France and Germany. The commonest species is *V. oleracea*, which is naturalised in the United States, and often called Feticus or Vetticost. There are several native American species.

Cornstone, an arenaceous or siliceous limestone, often mottled, and not infrequently concretionary. It usually occurs in those systems which are largely composed of reddish sandstones.

Cornucopia (Lat. *cornu*, 'a horn,' and *copia*, 'plenty'), in classical antiquities, the horn or symbol of plenty placed in the hands of emblematical figures of Plenty, Liberty, and the like, who are represented as pouring from it an abundance of fruits or corn. It is frequently used in architecture, sculpture, and heraldry.

Cornwall, a maritime county, forming the south-western extremity of England, and the southernmost part of the British Isles. It is peninsular, tapering westward from Devonshire to the Land's End, bounded on the E. by Devonshire, on the N. by the Bristol Channel, on the W. by the Atlantic, and on the S. by the English Channel. No part of the county is more than 20 miles from the sea. The total length from Welcombe to the Land's End is 81 miles, and the extreme breadth from Morwenstow to the Rame Head 45 miles. The Scilly Isles, 24 miles W. of the Land's End, form part of the county. The area is 1365 sq. m., of which 63·4 per cent. is under cultivation. There are very extensive stretches of moorland, much rocky and barren, but a large proportion useful as mountain pasture. The surface of the county is very irregular, and a ridge of rugged, bleak, rocky hills, interspersed with moors, stretches from the Tamar to the Land's End, a continuation of the Dartmoor upland, and forming the watershed. Brown Billy (1368 feet) is the loftiest point in the county. As this range is nearer the north of Cornwall than the south, the principal rivers are on the southern side, and empty themselves into the English Channel. With the exception of a few unimportant creeks, there are only two harbours on the north coast—the estuary of the Camel, on which is Padstow, and the bay of St Ives. For nearly the whole of its length this north coast is formed of bold and picturesque cliffs; but at Perranzabuloe and Gwiltian there are hills of blown sea-sand, which have buried much good land. The southern coast is also for the most part bold and rocky, but indented with many headlands and bays. Between the Land's End (5° 41' 31" W.) and the Lizard Point (49° 57' 30" S.) is the deep indentation named Mount's Bay, from St Michael's Mount, with the harbour-works of Penzance. East of the Lizard is Falmouth Bay, into which opens Falmouth Harbour, one of the finest in Britain. On the eastern boundary of the county is another of the great havens of the kingdom, Plymouth Sound. The estuary of the Fowey also affords a small but per-

fectly sheltered deep-water harbour—of considerable importance in the middle ages. The chief river is the Tamar, which practically divides Cornwall from Devon, rising within 3 miles of the north coast at Wooley Barrows. It is tidal, and navigable for 19 miles (total length 59) from its embouchure in Plymouth Sound. Its principal Cornish tributary is the Notter, which enters it through the estuary of the Lynhir, and is navigable for 5 miles. The lower part of the estuary of the Tamar is called the Hamoaze. The Fowey is 30 miles long, and navigable for 6. The Fal is 20 miles long from its source to Falmouth Harbour, into which several smaller streams empty themselves through tidal creeks. The Camel (also called the Alan) is 29 miles long, 10 miles being tidal. There is a tradition that a large tract of land between the Land's End and the Scilly Isles was submerged by the sea. This is the fabled Lyonesse.

Cornwall is mainly composed of clay-slate, provincially called *killas*, which is broken along the higher ground by the protrusion of bosses of granite, in five larger and many smaller masses, probably connected beneath the surface. Associated with the granite are schist and allied rocks, and there are many dikes of quartz- and felspar-porphyr, locally termed *elvans*. The slates are interspersed with igneous rocks, interbedded and intrusive, and there has been much alteration. The Lizard district presents the most complex series in the kingdom. Serpentine and gabbro are the most distinctive rocks here; but there are schists and gneisses and porphyries in singular variety. The stratified rocks of the east of the county are recognised as Devonian; in the central region Silurian are largely represented; the western may be still older; and the Lizard are believed to be partly Archean. Mining has been carried on in Cornwall from prehistoric times, and the county has been regarded as the *Cassiterides* (q.v.) of the Phœnicians and Greeks. The most profitable mines are near the junctions of the granite and *killas*, and the most important mining area at the present day is around Camborne and Redruth; the deepest and richest mine is Dolcoath, wrought to a depth of about half a mile. The county yields tin, copper, lead, iron, zinc, silver, cobalt, antimony, manganese, bismuth, tungsten, and arsenic in commercial quantities; and a greater variety of minerals (some unique) than any other part of the United Kingdom. Gold has been found in alluvial tin works or 'streams,' the largest nugget over two ounces. Of late years mining has been very much reduced, and almost all the mines now existing are tin, of which Cornwall yields nearly all that is raised in the kingdom. The output of copper is at present small. Next to tin, the most important mineral product is china clay (*kaolin*), the decomposed felspar of granite which has undergone the natural process of kaolinisation. The chief centre of this industry is the district north of St Austell. Here also is found a peculiar kind of granite called china-stone (*petuntze*).

The fisheries of Cornwall are extensive and important, and in favourable seasons large quantities of pilchards are caught by seining, cured, and exported to the Mediterranean, where they form a common Lenten food. Herring and mackerel fisheries are also extensive, and enormous quantities are sent by rail to London and various inland markets. The climate is generally mild, but damp. In the extreme west of the county snow seldom lies, and the winter temperature is such that plants live and flourish in the open air that require protection almost anywhere else in England. At Trevarrick, near St Austell, and Lamoran and Penjerick, near Falmouth, many foreign trees and shrubs have been successfully acclima-

tised. Camellias grow and flower in the open air as luxuriantly as the common laurel in sheltered localities. The gardens at Trescoe, Scilly, are quite tropical in character, from the variety and beauty of their tropical contents. This favourable climate has been turned to good account in the Scilly Isles and the Penzance district, by the development of market-gardening for the supply of early vegetables to the leading markets, particularly broccoli and potatoes, of which double crops are raised annually. With the exception of the peach, nectarine, and apricot, nearly all fruit-trees thrive and mature; and the banks of the Tamar are specially favourable to the growth of cherries and strawberries, for rail supply. As a general agricultural county (its moorlands excepted), Cornwall stands high: the soil is rich; crops are abundant, and in some localities very early.

There are very few manufactures; and most of the inhabitants, since the falling off in mining, are employed in agriculture. The population in 1881 was 329,484. Cornwall contains one parliamentary borough—Falmouth and Penryn, and six county divisions. It returned 40 members prior to 1832, 14 till 1867, 12 till 1885, and now 7 in all. The bishopric of Cornwall, merged in that of Exeter since Saxon times, was restored in 1876, and the see fixed at Truro.

Cornwall remained in the hands of its Celtic inhabitants, and under the rule of the British Church, with more or less completeness, until it was finally subjugated by Athelstan in 936. The ancient Cornish language belonged to the Cymric or Brythonic group of the Celtic tongues (see CELTS), and was akin to Welsh and Breton. It was generally spoken until the reign of Elizabeth, and it was not until 1678 that it finally ceased to be used in public worship. It lingered in the extreme west of the county until the early part of the 18th century; Dolly Pentreath (?1676-1778) of Mousehole is popularly regarded as the last who spoke it; while words and phrases have been handed down to the present day. The literature comprises a vocabulary dating probably from the 13th century, and some sacred dramas not earlier than the 14th. See Norris's *Ancient Cornish Drama* (1859); Whitley Stokes's editions of *The Life of St Meriasek* (1872), of *The Mystery of the Creation* (1864), and of the *Glossary of Cornac* (1864); the glossary of words still in use in Cornwall, published by the English Text Society in 1880; a paper by Lach-Szyrna in the *Journal of the Royal Institution of Cornwall* for 1883; and Jago's *English-Cornish Dictionary* (1887).

Cornwall abounds in rude stone and allied monuments—circles, remains of huts, menhirs, cromlechs, artificial caves or fogous, cairns and barrows, inscribed stones, and early crosses. The mediæval antiquities are less important, the most noteworthy being the remains of the castles of the ancient earldom, created into a duchy in 1337 for the Black Prince. The eldest son of the reigning sovereign is Duke of Cornwall; and the revenues derived from the duchy by the Prince of Wales average £61,000 a year. In the management of the affairs of the duchy the Prince is assisted by a council, the chief officer of which is the warden of the Stannaries, by whose vice-warden the Court of the Stannaries, which has the local regulation of mining affairs, is held. See Tregellas's *Cornwall* (4th ed. 1884), and other works cited there.

Cornwall, a port of entry of Ontario, at the mouth of the Cornwall Canal, and separated by the St Lawrence from New York state. It is on the Grand Trunk Railway, 67 miles SW. of Montreal, and has, among other factories, one of the principal woollen-mills in the Dominion. Pop. 2033.

Cornwall, BARRY. See PROCTER.

Cornwallis, CAROLINE FRANCES, was born on the 12th July 1786, the daughter of the rector of Wittersham and Eltham, in Kent. She acquired a thorough knowledge of Latin and Greek, and making herself conversant with nearly every study which occupies thoughtful men, from an early age she carried on a correspondence with many eminent persons. Her refusal to accept the hand of Sismondi did not forfeit his friendship, and she lived much in Italy. Her first work, *Philosophical Theories and Philosophical Experience*, by a Pariah (1842), was the first of a series of twenty 'Small Books on Great Subjects,' the said subjects including the Connection of Physiology and Intellectual Science, Ragged Schools, Criminal Law, Greek Philosophy, and the History and Influence of Christian Opinions. Miss Cornwallis also published in 1847, *Pericles, a Tale of Athens*. She died at Lidwells, in Kent, 8th January 1858. See her *Letters and Remains* (1864).

Cornwallis, CHARLES, MARQUIS, an English general and statesman, son of the first Earl Cornwallis, was born in London, December 31, 1738, and was educated at Eton and the Military Academy of Turin. He served as aide-de-camp to the Marquis of Granby during part of the Seven Years' War; in 1766 was made a colonel; four years later, governor of the Tower of London; and the year after a major-general. In 1760 he had been returned to parliament for the family borough of Eye. Though personally opposed to the policy of forcing taxes upon the American colonists, he accepted a command in the war, and with an inferior force gained a victory over General Gates at Camden in August 1780, and more than held his own against General Greene at Guilford, March 1781. But his operations were hampered by the incapacity of his superiors, Howe, and after him, Clinton; and at length he was forced to surrender with all his troops at Yorktown, Virginia, 19th October 1781. This disaster proved the ruin of the British cause in America, and was the occasion of much dissatisfaction, resulting in a change of ministers at home. Cornwallis, however, who was high in favour with the king, escaped censure. In 1786 he was appointed governor-general of India and commander-in-chief, and in this double capacity distinguished himself by his victories over Tippoo Saib, and by unwearied efforts to promote the welfare of the natives, that proved less successful than they deserved. He returned from India in 1793, when he was raised to the rank of Marquis. As lord-lieutenant of Ireland, with Castlereagh as his secretary, he crushed the '98 rebellion, and showed a rare union of humanity and vigour in his measures for the pacification of the country. As plenipotentiary to France he negotiated the peace of Amiens in 1802, but showed little skill in diplomacy. Reappointed governor-general of India in 1804, he died at Ghazipur, in the province of Benares, October 5, 1805, on his way to assume the command of the army in the Upper Provinces. See his *Correspondence*, edited by Charles Ross (3 vols. 1839).

Coro, a town of Venezuela, in Falcón state, lies about 210 miles WNW. of Caracas, near the Golfete de Coro. It has a fine aqueduct, and a college; but it has greatly declined since the period 1527-78, when it was the capital of the Spanish province. Pop. (1887) 8881. Its port is La Vela, 7 miles NE. by rail.

Corolla. See CALYX, FLOWER.

Corollary, a proposition the truth of which appears so clearly from the proof of another proposition as not to require separate demonstration.

Coromandel Coast is a name used vaguely for the major part of the eastern coast of what is now the province of Madras, on the west shore of the Bay of Bengal. It has hardly a single safe place of refuge for large vessels. The name is probably a corruption of *Cholamandalam*, 'country of the Cholas,' an old Dravidian people.

Coro'na, or CROWN, in Botany, an appendage of the corolla in some flowers; sometimes developed as a crown-like circlet within the petals, as in the common white narcissus, or prolonged like an internal united corolla, as in the daffodil. Much discussion has taken place as to its morphological nature, at first as to whether it was to be regarded as composed of modified stamens or supernumerary petals. But in many Caryophyllaceæ (e.g. *Lychnis*) each petal is seen to bear a *ligule*, so called from its resemblance to that of a grass-leaf (see GRASSES). These are regarded as of stipular origin; and in this way we come to look at the corona of a narcissus as composed neither of modified petals nor stamens, but of the united petaline stipules. See STIPULE.

Corona (Lat., 'a crown'), in Architecture, the drip, or lower member of the projecting or upper part of a classical cornice (see ENTABLATURE). The term corona is also applied to the apse or semicircular termination of the choir. Corona is also applied in ecclesiastical nomenclature to a chandelier, in the form of a crown or circlet, suspended from the roof of a church.

a, the Corona.

Corona. See SIX.

Corona Borealis, a small and bright constellation near Hercules.

Coronach, a name formerly used for the funeral dirge amongst the Irish and the Scottish highlanders. The dirge, disused in Scotland, is in Ireland now commonly known as the *keen*.

Coronation. The practice of placing a crown on the head of a monarch at the commencement of his reign is very ancient, and there is probably scarcely any country in which it has not been followed in one form or another. Generally it has been accompanied by what was regarded as the still more solemn rite of anointing with oil, a ceremony which, from the times of the ancient Hebrews to our own, has been peculiarly significant of consecration or devotion to the service of God. In England, before the Norman Conquest, the term was more usually 'hallowing' or consecration than coronation; but it would seem that the ceremony as then performed at Kingston-on-Thames or Winchester was in all essentials the same as that which now takes place in Westminster Abbey, though now the ceremony is a mere pageant. Detailed accounts of many English coronations, from Richard I. downwards, have been preserved.

There have been considerable variations from time to time in the oath. Originally the king pledged himself to three things—peace and reverence to God and the church, justice to the people, the upholding of good and abolition of bad laws. In Edward II.'s time it became more precise, and assumed the form of question and answer. The present form was settled after the Revolution of 1688. By it the sovereign, in a series of responses to questions by the Archbishop of Canterbury, swears to govern the people of the United Kingdom according to the statutes in parliament agreed on; to cause law and justice, in mercy, to be executed; and to preserve and maintain the Protestant religion established by law. This oath was held

both by George III. and George IV. to prevent them from granting Catholic Emancipation, and was also by many regarded as an obstacle to the disestablishment of the Irish Church (see Bishop Phillpotts, *The Coronation Oath*, 1828). The treaty of Union between England and Scotland provides that the oath of the preservation of the

Coronation Chair of the Kings of England.

government, worship, and discipline of the Church of Scotland should be taken not at coronation but at the accession of the sovereign. For the ceremonies connected with coronation, see CHAMPION; *Chapters on Coronation* (1838); Planche, *Coronations of Queens of England* (1838); Jones, *Crowns and Coronations* (1883); and Sarah Tytler's *Life of Queen Victoria* (1886).

The Scottish coronation stone, the *Lia Fail* or 'Stone of Destiny,' was said by tradition to have been the stone which Jacob used for a pillow, and to have been brought to Ireland, and from Tara to Scotland, where it found a resting-place at Scone, till in 1296 Edward I. carried it to Westminster. It now forms part of the coronation chair, occupying the space beneath the seat. Skene, in his monograph (1869), asserts it to have been originally quarried from the rocks near Scone.

Coronation Gulf, an inlet connected with the Arctic Ocean, south of Victoria Land, in 68° 30' N. lat., and 110° W. long.

Coronea, a small town of Beotia, SW. of Lake Copais, where in 447 B.C. the Boeotians defeated the Athenians, and in 394 Agesilaus (q.v.) defeated the allied Greeks.

Coronella, a genus of non-venomous snakes in the family Colubridæ, to which the English Ringed Snake (q.v.), *Tropidonotus natrix*, also belongs. The genus is well represented in dry regions in Europe and North Africa. *C. lewis* or *austriaca* is a very common European species between two and three feet in length.

Coroner (Lat. *coronator*, *corona*, 'a crown'), a very ancient officer, in England, at the common law. The coronator is mentioned in a charter of King Athelstan, 905 A.D.; and the office is said to be of Saxon origin. But Bishop Stubbs (*Constitutional History*, vol. i. chap. 17) finds the origin of the office of the modern coroner in an ordinance of 1194 A.D. for the election in every shire of officers to keep the pleas of the crown, whence the name. In this light, the Lord Chief-justice of the Queen's Bench is the principal coroner in the kingdom, and may exercise jurisdiction in that capacity in any part of England. There are, however, particular coroners in every county in England, and in some counties three or four, or even more. Every borough having a separate court of Quarter Sessions has a coroner; but since 1888 boroughs have ceased to have a separate coroner unless the population amounts to 10,000. Coroners were formerly paid by fees on each inquest, but now by salary out of the county rate. The coroner is chosen for life, and the election, which formerly lay with the freeholders, rests, under the Local Government Act

of 1888, with the county-council, or with the town-council of a borough having the right to appoint one. A coroner may, however, be dismissed by the Lord Chancellor for inability or misbehaviour in his office. By the statute of Westminster the first (3 Edw. I. chap. 10), it was enacted that none should be chosen but lawful and discreet knights; and in the time of Edward III. there is an instance of a man being removed from the office because he was merely a merchant. Subsequently it was thought sufficient if a man had lands enough to entitle him to be made a knight; and Blackstone complains that in his time it had come to be sought for the perquisites, and not for the honour of serving the country. This motive has now ceased. The coroner is now usually a professional man, frequently a solicitor or a medical man.

The office of coroner is to some extent the only one in England charged with the investigation of crime. When the coroner cannot act, there is no authority to examine witnesses until a suspected person has been actually charged or accused before a magistrate. But even the coroner's duties are very limited. They are defined by 50 and 51 Vict. chap. 71, which consolidates most of the previous statutes. The coroner can inquire only into the causes of violent or sudden death, and into these only when the body has been found. When such a death happens, it is the duty of the constable to give notice of it to the coroner, who then summons a jury from the body of the county for the purpose of making an inquisition into the matter. The coroner presides over the inquisition, and the court thus constituted is a court of record. The jury consists of twelve men at least, who are sworn and charged by the coroner; and the verdict must be found by twelve. The inquest is to be held before the coroner in whose district the body shall be 'lying dead.' If any be found guilty by such inquisition of murder or other homicide, the coroner is to commit them to prison or take bail for their appearance at the assizes, according to the gravity of the offence, and he must certify the inquisition under his own seal and the seals of the jurors, together with the evidence thereon, to the court in which the trial is to take place. The accused may thereupon be put on his trial without other indictment. The coroner is empowered to summon medical witnesses, who are liable to a penalty for non-attendance. He has power to pay a medical witness one guinea for a simple examination, and two guineas if a *post-mortem* examination of the body has been made. Coroners are empowered to appoint deputies in case of absence from illness or other reasonable cause. Another branch of the coroner's office was to inquire concerning shipwrecks and treasure-trove; but this has been nearly superseded by the provisions of the Merchant Shipping Act, 1854. He is a conservator of the king's peace, in which capacity he is mentioned in the oldest treatises on the common law. As such, he may cause suspected felons to be apprehended, whether an inquisition has found them guilty or not. The coroner has likewise ministerial functions as the sheriff's substitute, in making out the panel of jurors, and in executing process in suits in which the sheriff is related either to the plaintiff or defendant. Latterly, the office of coroner has been the subject of consideration with a view to certain reforms of administration.

Coroners or crownors, as they were also called in England, are mentioned in many old Scottish statutes; and there is no doubt that the office, as well as that of alderman and mayor, existed in those parts of the country that were peopled by persons of Teutonic race. But it was abolished or fell into desuetude, probably in consequence of

the succession war and the French connection ; and in Scotland the duties are now chiefly performed by an officer appointed by the crown, styled the Procurator-fiscal (q.v.). In Ireland the office of coroner is regulated by 9 and 10 Vict. chap. 37. See Jervis, *Office and Duties of Coroner* (new ed. 1880).

In the United States the coroner is generally elected for a specified term by the voters of each county. He is authorised to employ deputies, assistants or clerks, as well as a legal adviser, and a physician to examine the cases which come before him. His powers and duties relating to the inquiry into cases of sudden or violent death are substantially the same as those of an English coroner. But he is confined to this function. Nor does the inquisition found before the coroner dispense with the necessity of an indictment found by the grand jury, as in England. In cases where the sheriff is absent or disabled, the coroner may sometimes act as an executive officer in his stead. He must in each term make a report under his official seal to the Court of Common Pleas of the state.

Coronet, an inferior sort of crown worn by persons of princely or noble rank, as a crown properly so called is worn by a sovereign. In England, coronets were worn by peers as far back as the reign of Edward III. ; but the definite form given to the coronets of the different orders of the peerage is of later date, as is also the practice of placing within the coronet a cap of crimson velvet lined with ermine and surmounted by a gold tassel. The use of coronets by barons began in the reign of Charles II. Peers wear their coronets on the occasion of the coronation of a sovereign ; and they are placed over representations of their arms, this being done even in the case of peers by courtesy. In 1665 Charles II. granted warrants to the Scottish and Irish kings of arms for the peers of those kingdoms to wear coronets similar to those of peers of England.

The following are the distinctive forms of the coronets in use in the United Kingdom : The coronet of the Prince of Wales differs from the royal crown only by the absence of one of the

points of more considerable height, with a pearl set on each, alternating with as many strawberry-leaves on the rim below. A viscount's coronet has sixteen, and a baron's six pearls set directly on the rim. The so-called pearls are always made of silver. No coronet belonging to a peer not of the royal family should be adorned with jewels.

The term *ducal coronet* is sometimes applied in heraldry to a decorative coronet like that of a duke, but with only three leaves, and without the cap, out of which (in place of out of a wreath) the crest issues.

The coronets of continental nobility are without caps, and otherwise differ somewhat from those in use in Great Britain. They are only used in blazonry, and are not worn on state occasions. The coronet of a French duke is like that in use in England, that of a marquis has three strawberry or parsley leaves alternating with three pearls, while a count's coronet has nine pearls. German dukes arch their coronets, and German counts often elevate their pearls. The coronet of the Dauphin of France was heightened with fleurs-de-lis, and arched with four or sometimes eight dolphins.

Corot, JEAN BAPTISTE CAMILLE, landscape-painter, was born at Paris, 26th July 1796, and was the son of a clerk. After being educated in the Lycée at Rouen, he became an assistant in a drapery establishment in Paris, and it was not till his twenty-sixth year that he was able to yield to his natural inclinations and begin the systematic study of art. He was instructed by Michallon and Victor Bertin, and in 1825 he settled in Rome, his small view of the Coliseum in the Louvre bearing that date. Here he studied under Aligny, *'L'Ingres des arbres,'* and in 1827 he returned to Paris, and contributed his *'Vue prise à Narni,'* and his *'Campagne de Rome'* to the Salon, where he constantly exhibited till the year of his death. His main sketching ground was at Barbizon, in the forest of Fontainebleau ; but he made two other visits to Italy in 1835 and 1843. His earlier productions are careful and precise in execution, and it was not until about 1840 that he asserted his full individuality, and developed that style, characterised by great breadth and delicacy, and sacrificing accuracy of detail to unity of impression and harmony of general effect, which marks the works of his maturity. He was not an artist of great variety or of very extended range in subject and effect. He was the painter of misty lakes and vaporous rivers, of the quiet of moonlight, of the tender moments of pure sunrise, or of softly coloured evening ; and these he has treated in the spirit of a true poet, introducing very appropriately his figures of peasants, or more frequently of nymphs and classical personages, who take their place most fittingly in scenes like his which tend towards the ideal and the idyllic. His works made their way slowly with the public, but wealth and fame came to him in the end. At the Salon he won medals in 1833, 1848, 1855, and 1867. In 1846 he received the Cross of the Legion of Honour, and in 1867 he became an officer of the order. He exercised a most powerful and clearly marked influence upon the younger French artists, with whom his genius, his frank kindliness, and his openhanded generosity rendered him the most popular of men and painters. In 1874, when the medal of honour of the Salon, which they expected to be bestowed on him, was awarded to Gérôme, they subscribed for a medal of their own, which they presented to *'le père Corot,'* as they were fond of calling him, only three months before his death, which occurred at Paris, 22d February 1875. Among his masterpieces may be named *'Danse de Nymphe,'* *'Macbeth,'* *'Homère et les Bergers,'* *'Oryphée,'* *'Souvenir de Montefontaine,'* *'Joueur de Flûte.'* He bequeathed his

arches. The coronets of other princes, sons of the sovereign, are without arches. Princes, sons of the above, have a similar coronet, with strawberry-leaves substituted for fleurs-de-lis. The coronet of a duke has above the rim of gold eight strawberry-leaves, of which five are shown in pictorial representation. That of a marquis has four strawberry-leaves, alternating with as many large pearls upon short points. The coronet of an earl has eight

'Dante and Virgil' and his 'Hagar in the Desert' to the Louvre. See French Lives by Dumesnil (1875), Robaut (1880), and Rousseau (1884).

Corozo Nut. See IVORY (VEGETABLE), and BUTTONS.

Corpora Quadrigem'ina. See BRAIN.

Corporal (more properly *Caporal*, from the French, which in the 16th century borrowed the Italian *caporale*), in the British army, is the grade of non-commissioned officer next below that of sergeant. When the regiment is on parade he falls in as a private soldier, but in barracks or camp he exercises certain disciplinary control over the privates, commands small guards, and does orderly duty. The distinctive badge is two Chevrons (q.v.) on the sleeve. The pay varies from 1s. 8d. to 2s. 4d. a day. There are 4 corporals to each troop of cavalry, and 5 to each Company (q.v.) of infantry. A lance-corporal is an acting corporal, who remains on private's pay, and wears one chevron only. In the artillery there is a special grade of non-commissioned officer below that of corporal, called a bombardier, with pay equal to the lowest rate of corporals in the infantry. The badge is one chevron, and there are acting bombardiers, but no lance-corporals. In the engineers the corresponding rank is that of second corporal. In the Household cavalry the title of *corporal of horse* is given to the non-commissioned officers corresponding to the troop sergeant-majors of other cavalry regiments (see COLOUR-SERGEANT). The pay is 3s. a day. A ship's corporal in the navy is a petty-officer under the master-at-arms, to aid in teaching the use of small-arms, guard against the smuggling of spirits on board, extinguish the fires and lights, and keep order below at night.

Corporal (Lat. *corpus*, 'the body'), a name given to the linen cloth, also called pall and chalice-veil, with which the celebrant covers what is left of the consecrated elements in the Holy Communion until the service is concluded.

Corporal Punishments. See FLOGGING.

Corporation. This, in England, is either aggregate or sole. A corporation aggregate is a society of persons authorised by law to act as one person, and to perpetuate its existence by the admission of new members. Without such legal authority the acts of the society would be regarded only as the acts of the individuals, and the property of the society would descend to the heirs of the individual members. A corporation sole consists of one person, the holder of a public office, and his successors, such as the sovereign, a bishop, the vicar of a parish, and most perpetual curates. The only Scottish instance is the minister of the parish. A singular modern instance is the Treasury Solicitor. As regards property, however, some of the public departments represented by their chief—e.g. the Secretary of State for War—are also corporations sole—i.e. property transmits without conveyance to each holder of the office. There are also *quasi* corporations aggregate, such as the churchwardens in England, the Commissioners of Supply in Scotland, the heritors of a Scottish parish, who cannot hold land in succession, and have no common seal. An intermediate class consists of parochial boards and school boards, which can hold land, but have no common seal.

A corporation could formerly be established only by charter from the crown or act of parliament, unless, indeed, it existed by immemorial prescription; but of late years the exigencies of commerce have led to the passing of various enactments, by compliance with which any society of persons may acquire for themselves the character of a corporation (see COMPANY). Many important municipal

charters were granted by ecclesiastical authority—e.g. till 1835 Newcastle had only a charter from the bishop of Durham. Boroughs, too, had frequently delegated from the crown, or some subject superior with royal rights, the power of incorporating trades or crafts within their own territory. The freedom of the crafts or of the merchant guild may in general be acquired by apprenticeship or by services in the army or navy (see GUILDS). A corporation always receives a corporate name, by which it sues and is sued, and it must possess a common seal, which is the proper evidence of its intentions and obligations. The majority of the members are entitled to act within the powers of the corporation, and may, by a bylaw, even delegate—except in the case of municipal corporations—the power of acting to a certain number of the members. For these acts none of its members are personally liable.

Corporations, whether aggregate or sole, are divided into ecclesiastical and lay, and the lay are subdivided into civil and eleemosynary. The ecclesiastical are such as are composed wholly of clergymen in their ecclesiastical capacity, and are chiefly for the purpose of holding ecclesiastical property. Civil corporations include municipal corporations, the universities, the colleges of physicians and surgeons, learned societies, and many trading companies incorporated. Eleemosynary corporations are for the administration of funds for charitable and pious purposes, such as hospitals, the colleges in universities, which, unlike the universities, the English law holds to be subject to visitation, &c. An important consequence of these distinctions is the effect it has on the right of *visiting* a corporation, or exercising a legal superintendence over its proceedings. The crown is the visitor of the archbishops, each archbishop is the visitor of his suffragan bishops, and each bishop is the visitor of all the ecclesiastical corporations in his diocese. Civil corporations have no visitor, but in both England and Scotland they are of course liable to be restrained by the courts where anything *ultra vires* is attempted. Eleemosynary corporations in England are visited by the founder and his heirs, or such persons as the founder appointed to be visitors, and in default of such persons, by the Court of Chancery. To some extent similar functions have devolved on the Charity Commissioners (q.v.).

A corporation may be dissolved by the death of all its members, or of such number as leaves not enough to make new elections in the way the charter requires; by forfeiture of the charter through breach of its conditions; by surrender of the charter; or by act of parliament. In all such cases the lands of the corporation revert to their several donors; the creditors, however, if any, being entitled in the first place to insist on a sale and distribution of the property, whether in a sequestration or otherwise.

Corporations, as has been pointed out in the American Civil Rights Act of Congress, are liable to the ordinary laws and treaties of the country, but are not citizens in the sense of exercising a political or municipal franchise. The American law has also had occasion to emphasise the distinction between public corporations which may be affected by legislation, while the written constitution of America prohibits any interference with the rights of a private corporation. Further, according to American law, the franchises of a corporation are treated as realisable assets for creditors. The amount of property which may be held by a corporation in the States is frequently limited in the act or charter; and as regards charitable and religious purposes, a general law forbids the holding of more than \$50,000, or £10,000 worth. In the States less

importance is attached to the use of the common seal of a corporation than in Britain. For trade corporations, see the article GUILDS.

Corps d'Armée. See ARMY CORPS.

Corpse Candle. See CANDLE.

Corpulency. See OBESITY.

Corpus Christi Festival, the most splendid festival of the Roman Catholic Church. It was instituted in 1264 (see BOLSENA), in honour of the Consecrated Host and with a view to its adoration, by Pope Urban IV., who appointed for its celebration the Thursday after the festival of the Trinity, and promised to all the penitent who took part in it indulgence for a period of from forty to one hundred days. The festival is chiefly distinguished by magnificent processions. In France it is known as the *Fête Dieu*; in Germany, as the *Franken-namsfest*.

Corpuscles, BLOOD. See BLOOD.

Corpuscular Theory. See LIGHT.

Corpus Delicti, a criminal law term used in Scotland to signify the body or substance of the crime charged. To make out the corpus delicti is to prove that the crime charged has been committed; as, when a person is charged with murder, it must be proved that the deceased came by his death in consequence of the injury libelled, and not, for example, by natural causes.

Corpus Juris Civilis is the whole body of the Roman or Civil Law, as comprised in the Institutes, the Digest (or Pandects, q.v.), the Code, and the Novellæ (see CODE, LAW). In like manner the *juris canonici* is the body of Canon Law (q.v.).

Correction, HOUSE OF, a prison for the reformation of petty offenders. See PRISON, REFORMATORY.

Correction of Proofs. See PROOFS.

Correggio, ANTONIO ALLEGRI DA, was so styled from the place of his birth, a small town 20 miles E. of Parma, where he was born in 1494. Modern research has proved the inaccuracy of Vasari's highly coloured account of his struggles and poverty. His father, a well-to-do merchant or tradesman of Correggio, seems to have designed him for a learned profession; but he turned to art, studying under his uncle and three other masters. He is believed to have gained some idea of foreshortening and perspective from the works of Mantegna at Mantua, which he visited in 1511, and to have been influenced by the graceful colouring of Lorenzo Costa. At the age of about twenty he returned to his native town, where in 1514 he painted an altarpiece for the Franciscan convent, a work, now in the Dresden Gallery, distinguished by more gravity, restraint, and religious feeling than characterise his later productions. In 1518 he began his great series of works at Padua by a beautiful fresco series of mythological subjects for the decoration of the convent of San Paolo, which are still in an excellent state of preservation. From 1521 to 1524 he was engaged upon his subject of 'The Ascension' in the cupola of the Benedictine church of San Giovanni, a fresco in which the master's power is fully visible. His next great monumental work was the decoration of the cathedral of Parma, commissioned in 1522. The subject chosen for the interior of the main dome was 'The Assumption of the Virgin.'

During the execution of these frescoes Correggio was also much occupied with easel-pictures in oils. Among these are his very celebrated Adoration of the Shepherds, known as 'La Notte' or 'The Night,' commissioned in 1522, now in the Dresden Gallery, a work of marvellous softness and delicacy. Five years later he painted 'Il Giorno,' an exquisite picture, now in the Parma Gallery.

In 1530 Correggio removed from Parma to his native town, where, in the same year, he purchased an estate, and in 1533 some additional land. The production of the 'Jupiter and Antiope' of the Louvre, 'The Education of Cupid' of the National Gallery, London, of the 'Danaë' of the Borghese Gallery, and of the 'Leda' of the Berlin Museum, has been assigned to the painter's later years; and the 'Reading Magdalene,' of which the picture in the Dresden Gallery is now regarded as merely a 17th-century copy, was completed in 1528. He died at Correggio, at the early age of forty, on the 5th of March 1534, and was buried in the cloister of the Franciscan church of the place.

The art of Correggio is distinguished by its grace and gaiety, by its sunny sensuous charm. His figures are rendered with a bounteous sweeping outline, and he delineates rapid motion and momentary attitudes and expressions with singular power. His colouring possesses the finest delicacy and luminosity; his foreshortening is bold and skilful, if sometimes rather extravagant; and, above all, he was unrivalled as a master of subtle and refined chiar-oscuro. His works present the strongest possible contrast to the gravity and restraint, to the reverential feeling and the accurately balanced compositions, of the earlier devotional painters of Italy.

His only son Pomponio, by his wife Girolama Merlino (whom Correggio married in 1520, and who died in 1529), was born in 1521, and was alive in 1593. He also was known as a painter, and an altarpiece from his hand is in the Academy at Parma. See Julius Meyer's article in the *Allgemeines Künstler-Lexicon* (1870; Eng. trans. edited by Mrs Heaton, 1876), and J. P. Richter's in *Kunst und Künstler* (1879).

Corregidor is the name given in Spain to the principal magistrate of a town, appointed by the king. Readers of *Gil Blas* will remember his functions and the terror of his name to evil-doers. The Portuguese corregidor has administrative but not governing powers.

Correlation of Forces. See ENERGY, FORCE.

Correlation of Organs, the close mutual dependence between different systems and structures within the organism. A three- or four-chambered heart is correlated with the development of lungs; animals with an allantois never have gills; the development of a placenta is all but co-extensive with the presence of milk-glands. So among plants parallel venation of the leaves is almost constantly correlated with monocotyledonous structure; and a restriction of the vegetative leaf-organs will show itself in a counterbalancing modification of flowers and fruit. From the time of Aristotle such correlations have been noticed; but it was not till after the work of Cuvier, Geoffroy St-Hilaire, Goethe, and their contemporaries, that the fact was adequately appreciated. It was only then, in other words, that the organism began to be really understood as a unity of mutually dependent parts. The general proposition that all the organs are partners in the general life, that if one member suffer all the members are more or less influenced, is sufficiently self-evident. But beyond this there are the special facts which show that certain organs are knit together by closer physiological bonds than others, that certain structures stand or fall together, that certain characters have a contemporaneous appearance in the historical evolution. The facts are well known; their explanation in many cases is difficult or quite obscure. See EVOLUTION, VARIATION.

Correspondence Classes, a method of instruction first fully developed in the United

States by the Chautauqua Literary and Scientific Circle (1878), and since adopted in England—e.g. under the Oxford University Extension (1889). See CHAUTAUQUA.

Corrèze, a French department, formed out of part of the old province of Limousin, and taking its name from a river, the Corrèze, flowing 52 miles south-westward to the Vézère. Area, 2265 sq. m.; pop. (1872) 302,746; (1886) 326,494. The chief rivers of Corrèze are the Dordogne, the Vézère, and the Corrèze. The surface of the department is mountainous, especially in the north and east, where it is broken in upon by offsets from the Auvergne Mountains, which, in Mont Odonze, attain a maximum altitude of 3129 feet above the sea. The lower slopes are clad with forests, but the district is in general sterile. Minerals, particularly coal, iron, lead, alabaster, and granite of various colours, are found. The department is divided into the three arrondissements of Tulle, Brive, and Ussel. Tulle is the chief town.

Corrib, LOUGH, a lake of counties Galway and Mayo, the second largest in Ireland. Lying only 30 feet above sea-level, it is of very irregular shape, 25 miles long from NW. to SE., and 1 to 6 broad, with an area of 68 sq. m. From its south end, 4 miles north of Galway, it discharges its surplus waters by Galway River into Galway Bay. It receives the waters of Lough Mask, at its north end, through the Pigeon Hole and other caves, as well as those of the Clare and other smaller rivers. It contains many islets, and to the west are mountains 3000 feet high, whilst near it are many stone-circles.

Corrichie, a moor on the borders of Kincardine and Aberdeen shires, 15 miles W. of Aberdeen. Here on 28th October 1562 Queen Mary's half-brother, the Earl of Moray, defeated the Catholic Gordon, Earl of Huntly, who himself fell in the battle, while his two sons were taken prisoners. There is a rather poor ballad on the subject, in broad Aberdeenshire dialect, quite at variance with the facts of history, and first printed in Evans's *Old Ballads* (1777).

Corrie (Gaelic *coire*, 'a caldron' or 'large pot'), a term applied in Scotland and Ireland to semi-circular recesses or cirques in mountains, generally flanked by steep and lofty cliffs. They vary in character according to the nature of the rocks. In some the declivities are rounded and smooth, but generally they are broken and rugged, the bounding cliffs rising to heights of 1000 or even 2000 feet. Similar features are recognised in many mountain-regions all the world over. The origin of corries has been a subject of some controversy by geologists. There can be no doubt, however, that they are due in the first place to denudation—to the action of torrents and springs and frosts, aided and directed by the natural division-planes of the rocks. Many of the corries in Scotland and other mountainous countries have been occupied by glaciers—the grinding action of which has tended to modify the form of the ground. Not a few corries are occupied by mountain-tarns.

Corrientes, a province of the Argentine Republic, between the Paraná and Uruguay rivers, extending from Entre Rios to Misiones territory, with an area of 40,000 sq. m. The surface is generally flat, with numerous lakes and swamps, but has undulating stretches along the Paraná and in the east, and is heavily wooded in parts. Lake Iberá, a group of lakes and swamps covering some 1800 sq. m., is surrounded with a jungle, in which the 'tacuara' bamboo (30 feet) is conspicuous; and here jaguars and alligators abound. The mean temperature (72° F.) is the highest in the republic, but the extremes (44°–98°) are not so excessive.

As in Paraguay, Guarani is the common language, Spanish being employed only by the official and educated classes. Cattle-raising is the chief occupation; agriculture is very backward. Pop. (1888) 300,000.—The capital, Corrientes, is almost hidden among orange-groves, 15 miles below the confluence of the Paraná and the Paraguay, and takes its name from seven currents formed by points of rock above the city; vessels of 9 feet draught can reach the town at all seasons. Steamers from Buenos Ayres (832 miles) touch here almost daily, and in 1887 a railway was begun to Monte Caseros (235 miles). Pop. 18,000.

Corrieveekin (Gael., 'Brecan's cauldron'), a whirlpool or dangerous passage scarcely a mile broad, off the west coast of Argyllshire, in the strait between Scarba and Jura isles. It is caused by the meeting of tides (running 13 miles an hour) from the north and west, in the narrow passage into the Sound of Jura, round a pyramidal rock, which rises with rapid slope from a depth of 100 fathoms to within 15 feet of the surface.

Corroboree is the Australian name for a gathering of aborigines, generally in large numbers, at which dances and other exercises are gone through with much excitement. They usually take place on moonlight nights, and may last the whole night through.

Corrosive Sublimate, the popular name of the highly poisonous bichloride of mercury (mercuric chloride). See MERCURY.

Corrugated Metal. Iron and other metals in sheets and plates have communicated to them enormously increased rigidity and power to resist buckling and collapse by being corrugated. The process is merely an application to metallic substances of the old contrivance of 'goffering' or 'piping,' by means of which frills are stiffened and kept in shape. The metal to be corrugated is passed between pairs of rollers with ridged surfaces, the ridges of one fitting into the hollows of the other, and the sheets or plates operated on are bent and compressed into the wavy outline of the rolls. Walls and roofs of light and temporary buildings are extensively made of corrugated galvanised iron—i.e. sheet-iron first corrugated and subsequently coated with zinc by dipping the sheets into a bath of the liquid metal. The most important mechanical application of corrugated metal has been for the flues of large steam-boilers. About 1878 a system of annular corrugated iron flues was introduced, which increased the resistance of the flue to collapse, and saved fuel because of the greater heating surface presented by the corrugations. A spiral corrugated flue gives the greatest amount of strength.

Corruption of Blood. See ATTAINDER, TREASON.

Corrupt Practices Act. See BRIBERY.

Corry, a town of Erie county, Pennsylvania, situated at the junction of several railways, 37 miles SE. of Erie. It has machine-shops, saw-mills, and oil-refineries. Pop. (1870) 6809; (1880) 5277.

Corsair, a pirate or sea-robber, and specially any of those rovers who in former times cruised from the Barbary ports, as Algiers, Tunis, or Tripoli, and became the terror of merchantmen in the Mediterranean and the Atlantic Ocean, ravaging the coasts and seizing shipping, as far north as Cornwall, Baltimore in Cork, and even Iceland. Though piracy on a small scale had long prevailed, the immediate cause of the sudden development of corsair states and fleets at the beginning of the 16th century was the persecution of the Moors in Spain: the exiles looked for vengeance, and their necessities

compelled thieving; and when they were joined by adventurers from the Levant and not a few Christian renegades, who were attracted by the spoils of the Indies, then coming to Spain, they soon became a formidable power, and founded citadels and states (see ALGIERS, TUNIS, TRIPOLI, SALLÉE). Their greatest leaders were the brothers Urûj and Kheyr-ed-din Barbarossa, the first pashas of Algiers. Kheyr-ed-din rose from a mere captain of a galley to be high admiral of Sultan Suleyman (Soliman the Magnificent), and defeated the combined imperial, papal, and Venetian fleets under Doria off Prevesa in 1538. Other famous corsairs were Dragut (Torghud), a Sardinian who died at the siege of Malta; Ochiaï (Ulûj 'Ali), who fought in the battle of Lepanto, 1571; Aidin Reis, or 'Drub-devil'; Sinan of Smyrna; Salih Reis; Ramadan; Ali Pichinin, &c. Many attempts were made to put down the corsairs, from Sir Robert Mansel's expedition in 1621 to Lord Exmouth's victory in 1816; but the jealousies of the European powers conspired to assure the pirates' immunity, and the Deys of Algiers levied blackmail upon Christian governments who wished to protect their trade. Nothing less than the French conquest could have suppressed so long-seated a disorder, which had infected the Mediterranean for more than three centuries. See *Corsairs of the Mediterranean*, by Stanley Lane Poole (1889).

Corsets. See STAYS.

Corsica, the fourth largest island of the Mediterranean and a French department, tapers southwards, somewhat in the form of a leaf with part of the stalk at the north end. It is 114 miles long by 52 miles broad, with 300 miles of coast-line. Area, 3378 sq. m.; pop. (1872) 258,507; (1886) 278,501. Corsica is separated from the twin island of Sardinia, double its size, to the south, by the Strait of Bonifacio. It is 54 miles SW. of Leghorn and 98 S. from Genoa. Though now part of France, the island belongs geographically, historically, and linguistically to Italy. The east coast, running nearly straight north and south, is broken only by the port of Bastia and Porto Vecchio. The west coast, of crescent form, is very rugged, deeply and manifoldly indented by bays and gulfs. The promontory into which the north coast projects runs 23 miles north beyond the general north coast-line, and is 6 to 9 miles broad. The interior is a labyrinth of mountains, in which, however, a principal chain traverses the whole island from north to south, dividing Corsica into two regions, an eastern and a western zone. These regions are each divided by transverse chains into parallel valleys deeply hollowed by watercourses plunging from the high summits. The highest elevations are about the middle: Cinto (8878 feet); Rotondo (8607); Pagli-Orba (8283). On the west side the mountains reach to the coast, but on the east, between mountains and sea, there extend alluvial plains, edged seawards with lagoons and swamps, highly fertile but malarious, so that in summer the occupants have to escape to the mountains. In the time of the Romans these plains were densely peopled, and recently eucalyptus plantations are beginning to overcome the malaria. The west zone is occupied mostly with primary strata, granite, and schistose rock; on the east side the mountains are cretaceous, with serpentine and porphyry. Corsica is watered by numerous streams, none navigable, with cascades glittering in all directions. On the east coast are the Tavignano, 47 miles long, from lake Nino; and the Golo, 52 miles long. On the west the longest is the Tàvavo, 34 miles long.

With the exception of the malarious coasts in the east the climate is highly salubrious. The soil is very fertile, and over 43 per cent. of the entire

area is returned by official statistics as arable land; yet in 1887 over 35,000 tons of flour, and large quantities of wheat and hay, were imported. Corsica presents a succession of climates and vegetation zones. On the lower slopes are olives, oranges, citrons, laurels and vines. Higher, up to 6250 feet, are magnificent chestnut-trees; higher still rise virgin forests of oak, pine, larch, &c. These again are overtopped by pastures. The highest summits are snow-clad for half the year. About one-sixth of Corsica is estimated to be covered with forest, but this includes in many places only confused thickets (*macchie*) of green oak, arbutus, myrtle, and broom, often serving as the hiding-place of bandits. Campo dell' Oro around Ajaccio and the country north of Bastia are among the most fertile districts of the Mediterranean. The mufion or wild sheep is found; also wild boars, large foxes, and small deer, but no wolves or bears. The venomous ant, *innafantato*, is peculiar to Corsica, where are also the *Malmignata* spider and the tarantula. The minerals of Corsica are yet little worked. Copper and silver-lead mines near Calvi are now being worked by an English company. Sulphide of antimony is successfully worked in Cape Corso. There are also iron and manganese ores. Among the valuable stones are red and blue granite, porphyry, jasper, alabaster, and marble; and the Orezza mineral waters have a high medicinal value. Agriculture is backward. In many parts tillage is carried on almost exclusively by Italian labourers ('Lucchesi'). The chief industries are fishing and rearing of cattle. Wines, timber, charcoal, olive-oil, and dried fruits are the chief exports. In 1862 Corsica exported only 4294 gallons of wine, whereas in 1887 over 546,000 gallons were sent to the French continent alone. In 1887 the total value of exports to countries other than France was £97,145, and of imports, £213,145. In 1888 a railway was opened from Bastia to Corte, which was being pushed on to Bocognano, 96 miles from Bastia; and two other lines, on the east and west coasts, were in construction.

Corsica is divided into 5 arrondissements: Ajaccio, Bastia, Calvi, Corte, Sartène. These are subdivided into 62 cantons, and these again into 363 communes. The capital is Ajaccio, but the most important town is Bastia. The language is a corrupt Italian. Though not industrious, the Corsicans are patriotic and brave.

In early times known as Cynos, Corsica in the 8th century fell to the Saracens, who in the 11th century yielded it to Pisa. Thence it passed to the Genoese. Genoese towers, that used to defend the bays against Saracen incursions, still add a picturesque trait to the landscape. The Genoese, unable to subdue the Corsicans, who had risen under General Paoli, surrendered Corsica to the French, who conquered it in 1768, since which time it has willingly united itself with France. See Boswell's *Account of Corsica* (1768); Ortolì's *Contes popul. de l'île de Corse* (1885); Paul Borde's *En Corse* (1887); and for 'the Corsican,' BONAPARTE, NAPOLEON. For the blood-feud of the Corsicans, see VENDETTA, and Prosper Mérimée's powerful picture of Corsican life, *Colomba* (1841).

Corsite, a variety of Diorite (q.v.), composed of anorthite-felspar, hornblende, and a little quartz.

Corslet, a kind of cuirass, formerly the usual body-covering of pikemen. It was made chiefly of leather, and was pistol-proof.

Corsned. See ORDEAL.

Corso, an Italian word used to express not only the racing of riderless horses, but also the slow driving in procession of handsome equipages through the principal streets of a town, such as almost always takes place in Italy on festivals.

This custom has given a name to many streets in almost all the larger towns of Italy. The best known of these is the Corso in Rome, which is the scene of the celebrated diversions of the Carnival.

Corsen, **WILHELM PAUL**, a great German philologist, was born at Bremen, January 20, 1820. After studies in philology at Berlin, especially under Boeckh and Lachmann, and two years spent in teaching in a gymnasium at Stettin, he was called in 1846 to lecture at Schulpforta, and there he remained till 1866, when ill-health compelled him to retire to Berlin. There, however, he continued his arduous studies until he died, a martyr to learning, June 18, 1875. His earliest great work is his treatise, *Ueber Aussprache, Vokalismus, und Betonung der Lateinischen Sprache* (2 vols. 1858-59; 2d ed. 1868-70). It was followed by *Kritische Beiträge zur Lateinischen Formenlehre* (1863) and *Kritische Nachträge zur Lateinischen Formenlehre* (1866). His second masterpiece is *Ueber die Sprache der Etrusker* (2 vols. 1874-75), in which he labours with great ingenuity and vast learning to prove against the world that the Etruscan language was cognate with that of the Romans. H. Weber edited from his papers *Beiträge zur italischen Sprachkunde* (Leip. 1876).

Cort, **CORNELIS**, known in Italy as Cornelio Fiammingo, a famous Dutch engraver, was born at Hoom in 1533 or 1536. He studied under Hieronymus Cock, and his early plates bear that master's name. In 1572 he went to Venice, and was hospitably received there by Titian, some of whose finest works he engraved, as well as those of other Italian masters. Cort next settled at Rome, where he founded an engraving school; and from this school sprang the most excellent Italian and Venetian engravers. He died at Rome in 1578.

Cortes, the name given in Spain and Portugal to the assembly of representatives of the nation, the origin and history of which varied greatly in the different kingdoms out of which modern Spain is formed. See ARAGON, CASTILE, &c.; also SPAIN and PORTUGAL.

Cortes, **HERNANDO**, the conqueror of Mexico, was born at Medellin, in Estremadura, in 1485, of a noble but decayed family. The longing for adventure which early filled his heart was not cured by two years' study at Salamanca. He sailed for San Domingo in 1504, and ere long accompanied Velazquez in his expedition to Cuba. After the island had been subdued he came into serious disfavour with the governor, but was reconciled, and became alcalde in the capital, Santiago. The discovery by De Córdova of Yucatan, and of New Spain (Mexico) by Grijalva, had already fired the ambitious mind of Velazquez, when Pedro de Alvarado, who had been despatched by Grijalva, arrived at Cuba; and his glowing accounts filled the governor with a fresh thirst for gain and glory. He hastened to fit out a new expedition, the command of which he gave to Cortes. Cortes sailed 18th November 1518, and one of the most romantic chapters in the history of the world began. The armament with which he entered on the conquest of a vast and civilised empire consisted, according to Bernal Diaz, of five hundred and fifty Spaniards, two or three hundred Indians, twelve or fifteen horses, with ten brass guns and some falconets. Scarcely had he touched at Trinidad when orders from Velazquez to supersede him reached the island. These Cortes refused to obey, and thus cut himself off from all hope save in success. He landed first in Yucatan, and entered New Spain at the river of Grijalva. Proceeding inland he reached Tabasco, and here he fought his first battle with the

natives. His victory gave him his invaluable interpreter, the beautiful and faithful Donna Marina. At San Juan de Ulua messengers from Montezuma, the king of Mexico, reached him, bringing rich presents, but objecting to his expressed desire for a visit to the king. Here when the faction of Velazquez within his little force began to express openly their hesitation about proceeding further, Cortes adroitly got his men to entreat him to change the purpose of the expedition into colonisation and conquest instead of mere trade, and was thereupon formally appointed captain-general and justicia-mayor.

He now founded Vera Cruz, and sent messengers to Charles V. He next united all opposing interests in that of the common safety by burning his ships behind him, and marched to Tlascala, whose warlike inhabitants, subdued after some hard fighting, became henceforward his ever-faithful allies. After some delay he started on his memorable march to Mexico, attended by some thousands of his Tlascalcan allies; and at Cholula a treacherous attempt, by orders of Montezuma, to entrap the Spaniards, was frustrated by his sleepless vigilance. On the 8th November 1519 he reached the capital, which Bernal Diaz says appeared when they first saw it like something in a dream, or like one of the enchanted castles in the book of Amadis. The city was situated in a great salt lake communicating with a fresh-water lake, and was approached by three causeways of solid masonry, one two leagues long, with wooden drawbridges at the ends. At the lowest estimate its inhabitants exceeded 300,000. Cortes had not been a week in the city before he had determined to seize the august person of the king, and hold him as a hostage; his pretext being a treacherous attack upon Vera Cruz. Montezuma was paralysed at the heroic audacity of his proposal, and was carried to the Spanish quarters, from which he was never to return. Seventeen of the king's officers brought from Vera Cruz were burned to death in his presence, and Montezuma himself put in irons the while. In general, however, but little apparent restraint was put upon him, and he was allowed to go to his temple accompanied by a guard of one hundred and fifty Spaniards. At length he was constrained to submit to a public act of vassalage to Spain, and to give gold to the value of 100,000 ducats.

But Cortes was far more than an ordinary *conquistador*; he inquired about the mines and the methods of cultivation, and made wide explorations into the country; while with characteristic religious zeal he destroyed the more hideous Mexican idols, and sternly forbade human sacrifices. Meantime, however, the Mexican hatred for the conquering invaders was beginning to surmount their fear, as they began gradually to discover that they were merely mortal men spite of the strange wonder of their horses and cannon, and moreover were miserably few in numbers. In the sixth month of his imprisonment Montezuma asked Cortes to depart. The conqueror craved delay, and learned a few days after the request that eighteen ships had arrived in the bay of San Juan. These ships had been despatched by Velazquez under Pamphile de Narvaez, who sent a favourable message to Montezuma. Cortes left Alvarado in command, and hastened with but a handful of men to meet Narvaez, whose force numbered 800 men; and at Cholula, amid a blinding storm, surprised him in an unexpected night-attack in which but three of his own handful of heroes fell. The defeated troops gladly embraced the cause of the conqueror.

Fourteen days after the defeat of Narvaez came the news from Alvarado that the Spaniards were besieged in their quarters in Mexico. Cortes at once collected all his men, marched to his lieutenant's

relief, and reached the city, 24th June 1520. He found himself face to face with a whole nation in arms under Montezuma's brother as popular leader. A general attack was soon made upon him, and not repulsed without a desperate struggle. On the third day the unhappy Montezuma appeared on a battlement with the view of pacifying his people, but was wounded by a shower of stones—an indignity which broke his heart. Cortes burned the two great idols of the city, but this did not terrify the Mexicans, and he now saw that he must leave the city. His dispositions were quickly made; the start was made at midnight, 1st July 1520. The first bridge was crossed safely by a pontoon which he had prepared for this purpose, but at once the lake was covered with a multitude of canoes, and so furious an attack made that it proved impossible to raise the pontoon to cross the second bridge. Soon the water was choked with a crowd of struggling horses and men, and the retreat became a confused and hopeless rout. The second and third bridgeways were both broken down, but it was at the third that the greatest loss occurred. In the horrors of that awful night (*la noche triste*) were lost 450 Spaniards, forty-six horses, his artillery, 4000 Indian allies, and most of the Mexican prisoners. At Otumba, whither the miserable handful of survivors had retreated, Cortes found himself encompassed with an innumerable host, and there was a desperate battle, in which every individual Spaniard performed prodigies of valour. The exhausted victors were kindly received by their Tlascalcan allies, and Cortes at once began preparations to repair his disaster.

On the 26th December 1520 Cortes reviewed his troops. He had still 550 foot-soldiers, with forty horsemen, and eight or nine cannon. Taking with him 10,000 Tlascalans he marched to Tezcuco, and contrived to form alliances with some of the surrounding Indian tribes. At length his brigantines, built at Tlascala, arrived, carried by a host of Tlascalans; and, after a perilous expedition round the lake, and many ineffectual attempts to come to terms with the Mexicans, he began the formal siege of the city. He himself, with three hundred men, took command of the brigantines, as, in his own words, 'the key of the whole war was in the ships.' After defeating the Mexicans on the lakes, and destroying innumerable canoes, he made a series of simultaneous incursions along the causeways. The Mexicans fought with the fury of despair, and the triumph of the Spaniards proceeded only at the cost of the gradual destruction of the buildings in the city. Meantime the Spaniards themselves suffered desperate hardships from the ambuscades of their sleepless enemy, and becoming impatient, they demanded a general attack, in which they suffered a severe repulse. Although famine and pestilence fought for the Spaniards—as many as fifty thousand Mexicans dying of these during the siege—the city had to be destroyed before it could be taken. It fell at length, 13th August 1521, after a siege of seventy-five days, hardly to be surpassed in the history of the world for obstinacy and valour. Scarce any booty was obtained, the ruined houses were filled with heaps of dead, and almost the entire city had to be rebuilt.

Cortes now showed his wisdom by attempting to restore the native institutions. He rewarded his men with *encomiendas* or grants of Indians for labour and assistance in colonisation. He was formally appointed governor and captain-general of New Spain in 1522. He next sent out Alvarado on an expedition which led ultimately to the conquest of Guatemala, Sandoval to the north, and Christoval de Olid to Honduras. The last, unfaithful to his trust, rebelled, and the indefatigable Cortes at once set out on a perilous journey to subdue him; but

finding his rebellious lieutenant assassinated before his arrival, he returned to New Spain (1528) to find Ponce de Leon invested with the powers of government. In May 1528 he arrived in Spain, was received with marked honour by the king, and created Marquis del Valle de Guaxaca. He returned in July 1530 as captain-general, but to his disappointment was not appointed also civil governor of New Spain. He was poor and broken in health, and henceforward had the continual mortification to see the government muddled by envious and incompetent men. During ten years he was constantly engaged in making new discoveries to the north of Mexico, but now, says Bernal Diaz, 'everything turned to thorns with him'; and in 1540 he returned to Spain. He accompanied the emperor in his unhappy expedition to Algeria, and was mortified by having his offer to take Algiers, if given the command, slighted and despised. Voltaire's story of his proud speech to the emperor as he stood on the step of his carriage: 'I am a man who has given you more provinces than your ancestors have left you cities,' is true in spirit, if not in fact. Cortes wished to return to Mexico, but was not allowed till his impending suits were settled. His last years were darkened by neglect, deepened by the domestic vexation of his daughter Donna Maria's repudiation by a great Spanish noble to whom she had been betrothed. He went to meet her at Seville, fell ill, and died in a small village near that city, 2d December 1547. His body was first buried at Seville, afterwards at Tezcuco, in the country of his conquest.

The great conquest of Cortes ranks as one of the most splendid achievements in the world's history, and indeed it is more like romantic fable than sober fact. Its hero was no common adventurer or mere courageous soldier, but a captain of admirable sagacity and resource, a statesman of rare penetration and foresight. To the reckless audacity of a Rupert he added the astuteness of a Hannibal—a combination that marks only the highest order of military genius. His whole character was constructed on heroic lines, and is marked with a certain conspicuous grandeur throughout. He was passionate, yet patient; fond of splendour, yet simple in diet; cruel sometimes, yet sincerely religious; silent and reserved, yet capable of inspiring the most devoted as well as the tenderest personal affection. In many things he resembles Caesar, and like him he possessed that rarest power of knowing, as De Solis says of him, 'how to be a superior without ceasing to be a comrade.' See Prescott's *History*, and the admirable Life by Sir Arthur Helps (2 vols. 1871).

Cortona (Lat. *Crotona*), a town of Central Italy, 69 miles S.E. of Florence by rail. It stands 2130 feet above sea-level, looking down on the Valle di Chiana and the Trasimene Lake, and is one of the oldest cities in Europe, with mighty cyclopean walls of Pelasgic origin, Etruscan and Roman remains, numerous handsome palazzi, a fine cathedral, and half a dozen churches. These are rich in paintings by many old masters, including Luca Signorelli (q.v.) and Pietro Berrettini or da Cortona (1596–1669). The Accademia Etrusca (1726) has its seat here; its museum contains a multitude of Etruscan sarcophagi, vases, &c. Pop. 3605.

Coruña, LA (ordinarily in English, *Corunna*; among seamen, *Groynne*), a fortified seaport of Spain, and capital of a province of the same name, situated about midway between capes Ortegal and Finisterre, on a peninsula in the Bay (*ría*) of Coruña, 263 miles N.W. of Leon by rail. The town divides itself naturally into the upper portion and the lower, called *Pescadería*, which, formerly

a haunt of fishermen, is now the centre of wealth and trade. The harbour is commodious and protected by forts; and in 1888 a long-desired quarantine harbour was completed. There are large cavalry and infantry barracks, and a handsome new college, preparatory for the university of Santiago; but few of the other buildings are striking. To Englishmen the most interesting object is the tomb of Sir John Moore, in the centre of the gardens of San Carlos. One mile north-west of the town stands the famous Torre de Hercules, restored by Trajan, which serves as a lighthouse, and is nearly 100 feet high. Coruña has still a considerable commerce, but its cattle trade, which once employed a small fleet to carry oxen to Portsmouth and Plymouth for the British army and navy contracts, has fallen off. The chief imports are sugar from the colonies, and American raw petroleum, dried cod, hides from Argentina, cheap German spirits, and English coal. The industries of the town include the manufacture of cigars, glass-ware, and canned meats and fish, as well as cotton-spinning. Pop. (1885) 34,202. Coruña dates its origin from the Phœnicians, from whom it was taken by the Romans in the 1st century B.C. To Englishmen Coruña has rare historic interest. Here in 1386 John of Gaunt landed to claim the crown of Castile in right of his wife, daughter of Pedro the Cruel; in 1554 Philip II. embarked here for England to marry Queen Mary; and in 1588 the great Spanish Armada, which had been refitted at this port, set sail for the conquest of England. Here also fell gloriously Sir John Moore (January 16, 1809), after having with but 14,000 travel-worn men defeated no less redoubtable an antagonist than Soult at the head of 20,000 Frenchmen, fresh and flushed with the expectation of victory. Few exploits in English history are prouder than his memorable retreat, closed by the brilliant victory that covered the embarkation of the British troops.

Corundum, a mineral consisting essentially of mere alumina, yet of great specific gravity—about four times that of water—and of remarkable hardness, being inferior in this respect only to the diamond. Mineralogists regard the Sapphire (q.v.) as a variety of corundum, and along with it the gems popularly known as Oriental Ruby, Oriental Topaz, Oriental Emerald, and Oriental Amethyst; but the name corundum is more usually limited to the coarser varieties. These, instead of exhibiting the brilliancy of gems, are in general of a dull and muddy appearance, and the crystals—which are usually six-sided prisms and six-sided pyramids—are externally dull and rough. The colour is various, often green, blue, or red, inclining to gray. Corundum is found in many parts of the world, and has long been used in India for polishing all gems except the diamond, which is too hard for it. Emery (q.v.), so well known as a polishing substance, is a variety of corundum.

Corvée is the name usually given to the obligation on the inhabitants of districts to perform gratuitous labour (such as the maintenance of roads) for the sovereign or feudal lord. The forced labour for the aristocracy was one of the grievances of the French peasantry, which led to the Revolution. See FRANCE.

Corvei (*Corbeia nova*), a Benedictine abbey on the Weser, near Hoxter, the oldest and most famous in early Saxony, founded in 822. It was a colony from the monastery of Corbie in Picardy, then part of the country of the West Franks. It received rich endowments; was the centre of great agricultural improvement and prosperity during the earlier part of the middle ages; and the seat of a school, founded by Ansgar, the Apostle of

the North, which flourished greatly in the 9th and 10th centuries, and was next in reputation to Fulda. Its abbots were numbered amongst the spiritual princes of the German empire. In 1794 it was made a bishopric by Pius VI. Its territory then extended to about 20 square miles, with 10,000 inhabitants. In 1803 it was annexed to Nassau, from which it was transferred in 1807 to Westphalia, and in 1815 to Prussia. The Gothic church has a magnificent interior, and contains a multitude of princely monuments. The library and archives of the cloister, which contained most valuable records of the early ages of German history, were mostly destroyed—the *Chronicon Corbejense*, an alleged record of this abbey from its foundation to the end of the 12th century (pub. 1823), being a forgery; but there are some genuine though meagre *Annales Corbeicenses* (648 to 1148) printed in the *Monumenta Germaniæ Historica*.

Corvette was a term applied to a flush-deck vessel, ship or barque rigged, having only one tier of guns, either on the upper or main deck. The term is no longer used in the royal navy. This class of vessels are now called cruisers. See NAVY.

Corvidæ, a family of crow-like birds, in the old order of Passeres, among which they are the strongest. The family is widely distributed, and includes towards 200 species. Their family features may be best learned from those of the individual members. See CHOUGH, CROW, JACKDAW, JAY, MAGPIE.

Corvînus, MATTHIAS, king of Hungary (1458-90). See MATTHIAS.

Corvo, the most northerly of the Azores (q.v.).

Corwen, a town of Merionethshire, North Wales, on the right bank of the Dee, at the foot of the Berwyn Mountains, 12 miles N.E. of Bala by rail. It is a great resort of anglers, and boasts traditions of Owen Glendower. Pop. of parish, 2708.

Coryate, THOMAS, was born at Odcombe, Somersetshire, about 1577, entered Gloucester Hall, Oxford, in 1596, but left like many better men without a degree, and after James I.'s accession lived by his wits, or rather his wit, about court. In 1608 he set out on a rambling journey on the Continent, passing through Paris, Lyons, Turin, Venice, Zurich, and Strasburg, and returning five months later with a record of 1975 miles, mostly on foot. His entertaining journal was at last published in 1611, with a huge collection of commendatory verses, as *Coryat's Crudities: Hastily gobbled up in Five Moneths' Travells in France, &c.* Next year, after dedicating his travel-worn shoes in his native church, he started again on his travels, visited Constantinople, Greece, Smyrna, Alexandria, and the Holy Land, and found his way by caravan to Mesopotamia, thence through Persia and Afghanistan to Agra, where he arrived in October 1616. In the December of the following year he died at Surat. Letters of his were printed in 1616 and in 1618.

Corybantes, the priests of Cybele (q.v.) in Phrygia.

Corygaum, a village in the presidency of Bombay, 16 miles S. of Poona, the scene of the last of the three battles which caused the subjugation of the Peishwa of the Mahrattas. Captain Staunton, with a native force of but 300 horse and 500 foot and 24 European artillerymen, fought with success the whole day long against 3000 infantry and 20,000 cavalry (January 1, 1818).

Corylaeæ. See CUPULIFERÆ.

Cor'ymb, a form of Inflorescence (q.v.) which may be regarded as a raceme in which the main

axis has been more or less arrested in development, while the lower flower-stalks are lengthened so as to bring their flowers almost to the level of those of the upper. As familiar examples may be cited hawthorn, candytuft, &c. After flowering, the main axis of a corymb often elongates into an ordinary raceme, as in many crucifers.

Corymbiferæ. See COMPOSITÆ.

Coryphæus (Gr. *koryphê*, 'the head'), the leader of the chorus in ancient Greece. The name is now used to signify those of the highest distinction in any art or science. The French *coryphée* is generally used of the principal dancer in the ballet.

Coryphene (*Coryphæna*), a genus of bony fishes, remarkable for the brilliancy of their colours. They are nearly allied to mackerels, belonging to the same family, Scombridae. For some not very evident reason they are often popularly called 'dolphins.' The body is somewhat elongated, and is laterally compressed; the scales are very small; the head of the adults bears a sharp crest. The colours of silver, blue, and yellow have great beauty and metallic brilliancy, whether the fish be darting with extreme rapidity in the sunlit water, or lie dying on the shore. Apart from their marvellous beauty, the coryphenes are well known for their habit of pursuing shoals of flying-fish. Sailors often catch them with a glittering bit of metal for bait. They are frequently seen in the Mediterranean (four species), and also in the Atlantic, Indian, and Pacific Oceans. The most familiar species is *Coryphæna hippurus*.

Coryza. See CATARRH.

Cos (often called by the Italian name of *Stanko*), an island of the Archipelago belonging to Turkey, off the coast of Asia Minor. It is 23 miles long and 5 broad, with a population of 20,000, mostly Greeks. Cos consists mostly of fertile and well-tilled plains, partially of hilly country; and exports lemons, grain, wine, cotton, and silk to an annual amount of about £50,000. Many ancient Greek remains are scattered over the island. The chief town, Cos or Co, is situated on the north-east coast. In early times Cos was famous for its wine, its amphore, and its fine 'Coan garments.' It was the birthplace of Ptolemy Philadelphus, of the painter Apelles, and the physician Hippocrates.

Coscinomancy, an ancient mode of divination by means of a sieve (Gr. *koskinon*) and a pair of shears. It appears to have been chiefly employed for the discovery of thieves. The sieve was supported or suspended by means of the shears, in some way not easily understood; a certain mystical form of words was then used, and the names of the suspected persons being mentioned in succession, at the name of the thief the sieve moved or turned round.

Cosenza, a town of Italy, capital of the province of the same name, formerly called *Calabria Citeriore*. It is situated 12 miles E. of the Mediterranean, and 262 SE. of Naples by rail, in a mountain-closed valley at the confluence of the Crati and the Busento, and suffers in summer from malaria. It is the seat of an archbishop, and has a cathedral, a fine court-house, and trade in oil, wine, silk, hemp, manna, grain, and earthenware. Pop. (1881) 18,686. The ancient *Consentia*, a city of the Brutii, was captured by the Carthaginian general, Himilco, and was forced to surrender (204 B.C.) to the Romans, who afterwards colonised it. Alaric (q.v.) died here 410 A.D.

Coshery, or COSHERING, in Ireland, was the ancient feudal right of a chief to quarter himself and his retainers on his tenantry at his own discretion.

Cosin, JOHN, a famous bishop of Durham, was born in 1594 at Norwich. Educated there and at Caius College, Cambridge, he became fellow of his college and secretary to Bishop Overall of Lichfield, next in succession chaplain to Bishop Neill of Durham, prebendary of Durham, rector of Elwick, archdeacon of the East Riding, rector of Brancepeth, master of Peterhouse, Cambridge (1634), and dean of Peterborough (1640). An intimate friend of Laud, he had already come into collision with the Puritans about his ritualistic reforms, and been denounced by Smart, a brother prebendary of Durham, as 'our young Apollo, who repairs the Quire, and sets it out gayly with strange Babylonish ornaments.' In later invectives his antagonist did not spare his pluralism and even his fondness for tobacco. Prynne denounced also his chapel services at Peterhouse. Cosin was soon deprived of his benefices by the House of Commons, whereupon he retired to Paris, and for nineteen years of exile kept up there a Church of England service. At the Restoration he recovered his preferments, and in December 1660 was consecrated Bishop of Durham, and soon by his splendid energy, enthusiasm, munificence, and administrative ability, made his a model diocese. His personal dignity and commanding presence were perfectly in keeping with his conception of the part of one who was not only a bishop, but a prince-bishop. During his first seven years he spent no less than £34,500 upon his two castles, his cathedral, the library at Durham, and deeds of general benevolence. Imperious in temper, he sternly repressed Puritan and Roman Catholic recusancy alike; for, however devoted to ancient ritual and order, he hated Popery, and never ceased to regret the perversion of his own 'lost son' who had forsaken his mother, the Church of England. He differed too from the rest of his party in his Puritan-like support of the strict observance of the Sabbath. During his last years Cosin earned great unpopularity by his opposition to the desire of the people of the Palatinate to be represented in parliament. He died in London, 15th January 1672. All Cosin's writings are inconsiderable, save his *Collection of Private Devotions* (1627), which was denounced by Prynne in his *Brief Survey and Censure of Mr Cosin's Cosening Devotions*. A lasting service to the church was his contribution, invaluable from his profound liturgical learning, to the final revision (1661) of the Book of Common Prayer. Bishop Cosin's works were collected in 5 vols. in the 'Library of Anglo-Catholic Theology' (1843-55). His *Correspondence* was edited for the Surtees Society by Canon Ormsby (2 vols. 1868-70).

Co-sine, Co-tangent, &c. See TRIGONOMETRY.

Cosmas, surnamed *Indicopleustes*, a merchant of Alexandria, who lived in the middle of the 6th century, and after having travelled much, returned to Egypt, where in monastic retirement he wrote in Greek a work of greater interest than value, in 12 vols., on Christian Topography, extending to countries as far as India. The work is included by Montfaucon in the *Collectio Nova Patrum Grecorum*, vol. ii. (Paris, 1706).

Cosmas and Damian, SAINTS, Arabian brothers, who practised as physicians at Ægea in Cilicia in the 3rd century A.D., and who were cast into the sea as Christians, but, according to the legend, rescued by an angel. Thereafter, burning and stoning having proved ineffectual, they were beheaded in 303. Their relics were translated from Bremen to Munich in 1649, and their names commemorated in the Canon of the Mass.

Cosmetics (Gr. *kosmō*, 'I adorn') are chemical preparations employed for improving the appearance of the skin and hair. Several of the

cosmetics in use are comparatively harmless, such as perfumed starch and chalk (see *ROUGE*); whilst others, such as *pearl white* (the subnitrate of bismuth, see *BISMUTH*), are more or less poisonous, and dangerous to use. At all times, the employment of cosmetics is to be discouraged, as the minute particles tend to fill up and clog the pores of the skin, and prevent the free passage of gases and vapours, which is so essential to the preservation of any animal organ in a thorough state of health.

Cosmic Dust. See *DUST*.

Cosmo de' Medici. See *MEDICI*.

Cosmogony, a theory of the origin of the universe (Gr. *kosmos*) and its inhabitants, such as is found in the mythologies of all peoples except those in the very lowest stages of culture. There is the utmost variety in the explanations given, the only idea that is at all widely spread being that in the beginning all things were held in solution by water. Other prevailing conceptions are those of the Phœnician and Egyptian generative world-egg; of the Hindu tortoise which supports elephants, themselves the actual bearers of the world; of the Polynesian air-god, Tangaloa, hovering over the waters. A very elaborate cosmogony is given in the Pehlvi *Bundehesh*, ascribing creation to the free-will of a personal deity, as distinct from primordial matter, and this more elevated conception the religion of Zoroaster shares with the Jewish alone.

In the *Sanchoniathon* we have presented in a Greek version a fragment of an interesting Phœnician cosmogony, which explains the origin of organic matter as due to a series of spontaneous emanations. But the most interesting cosmogonies we possess are the ancient Babylonian, of which one form is preserved in the Greek of Berossus, while another was deciphered by George Smith from the cuneiform inscriptions. These present startling identities with the creation story in the first chapter of Genesis.

Modern cosmogonists arrange themselves mainly according to their attitude to Theism (q.v.). Theists explain the world of matter and order as having come into existence at the omnific fiat. Pantheism (q.v.), again, holds the universe to be the very body and being of Deity, and as such to have been from all eternity. Most men of science, in modern times, stopping short of an actual cosmogony or genesis of the world, have pushed their inquiries into the order of development of its present state. Some assume the necessary existence of matter; with these there is no proper beginning of things, but an eternal round, under fixed laws of growth and decay.

In cosmogonical speculations, heat, air, atoms with rotatory motions, numbers—have all in turn been recognised as the fountain and causes of things. Of hypotheses as to the formation of our own rotating globe, of our system, and of all similar systems in space, the most notable is that of Laplace, founded on observation of the mutual relations of the planets, their common direction in rotation and revolution, their general conformity to one plane, &c., taken in connection with such facts as the rings of Saturn and the fundamental unity of the asteroids. Laplace had in some measure been anticipated by Kant. Thus arose the *Nebular Theory* (q.v.), the evidence for which was carefully marshalled by Sir William Herschel; and which is still regarded by some physicists as indicated by the general tendencies of the laws of nature. M. Faye has given his theory of the origin of the earth from meteorites, and discussed other cosmogonic theories in *Sur l'Origine du Monde* (1880). Following up this view of a formation of the planetary globes by natural causes, there have

been speculations as to the commencement and progress of organic life upon them, and communication of it from one planet to another (as by Sir William Thomson; and see Professor Tyndall's presidential address to the British Association in 1874). Darwin's work has completely altered the face of biological research and theory (see *EVOLUTION*, *DARWINISM*, and *SPENCER*). For the cosmogonies of the various nations, philosophies, and religions, see *MATERIALISM*, *THEOGONY*, *HEGEL*, *ADAM*, *CREATION*; as also the articles on the Scandinavian Mythology, on the Greek Religion, on Spontaneous Generation, and on various aspects of Indian speculation.

Cosmological Argument. See *GOD*.

Cosmos. See *COSMOGONY*.

Cosne, a town, with iron manufactures, in the French department of Nièvre, and on the right bank of the Loire, 122 miles SSE. of Paris by rail. Pop. 6684.

Cosquin, EMMANUEL, an eminent French folklorist, was born at Vitry-le-François in Marne, where his father was a notary, as well as *maire* for nearly twenty years, 25th June 1841. He made his studies at the college of his native town, taking at the close of his course the diploma of licentiate in law, and here he has lived ever since. He has contributed many articles on religious questions to the Conservative and Catholic journal, *Le Français* (since November 1887 incorporated with *Le Moniteur Universel*), as well as numerous articles on more general questions to other newspapers and magazines, and has translated *La vraie et la fausse Infaillibilité des Papes* (1873), and *Le Concile du Vatican* (1877), two works by Mgr. Fessler, general secretary of the Vatican Council. But his most important work was a series of articles from 1876 to 1881 in the pages of *Romania*, which at once arrested the attention of scientific folklorists everywhere. These were collected into two volumes, issued in 1886 as *Contes populaires de Lorraine*, perhaps the most really important contribution made to storiology since the classical collections of J. F. Campbell (1860-62) and Von Hahn (1864). The stories were taken from a limited region, and were for the most part poorer in detail than parallel versions found elsewhere, but they possessed in their scientific accuracy a value which belongs unhappily to but few collections of folk-tales available to the student. The theory of the origin and transmission of such stories that M. Cosquin supports in his admirable introduction and in his no less luminous than learned notes, is a development of that put forth by Benfey in the famous introduction to his translation of the *Panchatantra* (1859), that not only the bases of these stories but their combinations have been carried from India within the historical period. M. Cosquin's position has been vigorously assailed by Mr Lang and others, but has been as vigorously defended by himself. See *FOLKLORE*.

Cossacks (Russ. *Kasák*), a race whose origin is hardly less disputed than that of their name. The latter has been variously derived from words meaning, in radically distinct languages, 'an armed man, a sabre, a rover, a goat, a promontory, a coat, a cassock, and a district in Circassia.' The Cossacks are by some held to be Tartars, by more to be of nearly pure Russian stock; but the most probable view is that they are a people of very mixed origin. Slavonic settlers seem to have mingled with Tartar and Circassian tribes in the regions to the south of Poland and Muscovy, in the Ukraine and on the lower Don, and to have given to the new race, first heard of as Cossacks in the 10th century, a predominantly Russian character. On the conquest of Red Russia by Poland, numerous Russian

refugees fled to the Cossack country; and more on the Tartar conquest of Muscovy. The numbers of the Cossacks were also recruited from time to time by adventurers or fugitives from Poland, Hungary, Wallachia, and elsewhere; but in physique, as in language and religion, the Cossacks have always been mainly Russian. They distinguished themselves in war against Turks and Tartars, and were known as a powerful military confederacy in the 15th century. The kings of Poland and the czars of Muscovy employed them largely to defend their frontiers, especially against nomadic neighbours; but the connection between the Cossacks and their lords paramount was always very elastic, and was frequently repudiated to suit the convenience of either party. The Cossacks are still the outposts of Russian authority in Siberia, Central Asia, and the Caucasus. Living near, or, as 'free Cossacks' amongst, hostile peoples, they developed their peculiar military organisation—either forming a cordon of military settlements along the confines of occupied territory, or isolated camps in the nomad country beyond. Agriculture they eschewed; self-reliance and readiness at all times for defence or assault were their chief characteristics; though such of them as inhabited the banks of the Don and Dnieper, and their islands, became and still are skilful boatmen and fishers. Their political constitution was completely democratic; all offices were elective for one year only, and every Cossack might be chosen to any post, including the supreme one of Attaman or Hetman. This organisation they have in great measure retained, though the office of Hetman was abolished by the Emperor Nicholas, except as a title hereditary in the imperial family. There have been two main branches of the Cossacks—the Little Russian, or Ukraine, and the Don Cossacks. To the first belonged the Zaporogian Cossacks, those dwelling near the *Porogi* or falls of the Dnieper. From them again are descended the Tschernomerian Cossacks, those of the Kuban Valley and of Azov. From the Don Cossacks spring those of the Volga or of Astrakhan, of the Terek Valley, of Orenburg, of the Ural, and of Siberia. They furnish a large and valuable contingent of light cavalry to the Russian army, and are very patient of fatigue, hunger, thirst, and cold. The Don Cossacks give name to a province with an area of 61,886 sq. m., and a population of over 1,450,000 inhabitants, of whom 20,000 are Kalmucks. Though the Cossacks have generally been represented in the west of Europe as little better than fierce savages, they have left a very favourable impression on those who have dwelt amongst them. Jonas Hanway found them in 1743 'a civilised, and very gallant as well as sober people'; and many more recent travellers agree in asserting that in intelligence, cleanliness, refinement, and enterprise they are greatly the superiors of the average Russians. See Springer, *Die Kosaken* (Vienna, 1877); Wallace Mackenzie's *Russia* (1877); and Erckert, *Der Ursprung der Kosaken* (Berlin, 1882).

Cossimbazar (*Kasimbazar*) is a decayed city, which at the end of the 17th century was the chief English agency in Bengal. It stood on the Bhagirathi near Murshidabad (q.v.); but its site is now a swamp.

Cossus. See GOAT MOTH.

Costa, ISAAC DA. See DA COSTA.

Costa, SIR MICHAEL, a popular musical conductor and composer, was born at Naples, 4th February 1810. As he early showed a decided talent for music, he was sent to the Royal Academy in his native city for education, where he greatly distinguished himself and produced

various compositions (1825–29). He settled in England, and in 1831 his ballet of *Kenilworth* was produced with success. He was conductor at the King's Theatre (1832), at Covent Garden (1846), to the Philharmonic Concerts (1846), and to the Sacred Harmonic Society (1848). His great work, the oratorio *Eli*, produced at the Birmingham Festival of 1855 (where he conducted till 1879), raised him to eminence as a composer. *Naaman*, which was less successful, was first sung in Birmingham in 1864. From 1857 till 1877 he conducted at the Handel Festival, and in 1871 he became director of Her Majesty's Opera. He was knighted by the Queen in 1869. Costa was the author of several ballets, and of some operas, including *Malek Adhel* (1838) and *Don Carlos* (1844). As a composer he holds a respectable place in the second rank, but it is as a conductor that he will be longest remembered, Meyerbeer, in 1862, styling him 'the greatest *chef d'orchestre* in the world.' He died 29th April 1884.

Costa Rica, the most southerly of the five republics of Central America. It is divided into six provinces, and occupies the entire breadth from sea to sea between Nicaragua on the one side and Colombia on the other, with an area of 21,495 miles, or about two-thirds that of Ireland. The population, which is mostly concentrated in a central plateau of about 3500 sq. m., was in 1885 officially estimated at 213,785, including some 10,000 uncivilised Indians; but in 1886, again, an official estimate gave only 196,270. The whites are mostly of pure Spanish descent. Except on the coast, the country is generally mountainous, with many volcanoes, all under 11,500 feet; on the Atlantic slope dense forests prevail, but wide savannahs are more frequent on the Pacific side. The climate is mild and temperate in proportion to the elevation, and the soil of the valleys and uplands is very fertile. Prior to the discovery of gold in 1823, Costa Rica was a land of poverty, owing its title of 'The Rich Coast' solely to the anticipations of its first Spanish settlers; since then, foreign capital has opened up much of the country, and brought its products within reach of a market. Although rich in gold, silver, copper, and other metals, its chief industry is agriculture; but the population is very scanty, and only a twentieth part of the land is under cultivation. Besides valuable timber and dye-woods, it yields tobacco, sugar, bananas, cacao, caoutchouc, sarsaparilla, and vanilla, which, with hides, tortoise-shell, and mother-of-pearl, are largely exported. But the staple of trade is coffee, to which is principally due the reviving prosperity of 'the Coffee Republic.' Of the total of £577,000 exports in 1885, coffee represents over £435,000. The imports, chiefly manufactured goods from Great Britain, and wheat and other products from the United States, amounted in the same year to £640,000. The chief ports are Punta Arenas and Limón (q.v.); the other places of any note are San José, the capital, and the cities of Cartago, Alajuela, and Heredia (9000).

Discovered by Columbus in 1493, and probably first settled on his fourth voyage, in 1502, Costa Rica has made much the same history as its neighbours: *pronunciamientos* have been frequent; its present constitution (1872) is the ninth since the declaration of independence in 1821; and for the ten years preceding 1883 that constitution was practically suspended. The government is now, however, accounted the best and most liberal in Central America. The president is chosen every four years, and the members of congress are elected for the same term. There is a small standing army of 500 men belonging to the militia, which embraces all males between the ages of eighteen and thirty, while those from thirty to fifty-five form the

reserve; and while the Roman Catholic is the state church, religious liberty is guaranteed. In 1886 the revenue was £437,776, mainly derived from the government monopoly of spirits and tobacco, and the expenditure £540,565. The foreign debt was converted into a new obligation of £2,000,000 at 5 per cent. from January 1888, the interest being paid out of customs' revenue. In 1888 there were 110 miles of railway open, and 48 in construction, and 390 miles of telegraph.

See Peralta, *Costa Rica, its Climate, &c.* (Lond. 1873); *Costa Rica, Nicaragua, y Panamá, en el Siglo XVI.* (Madrid and Paris, 1883); and *Costa Rica y Colombia* (Madrid, 1886); also Calvo, *República de Costa Rica* (San José, 1887).

Costello, LOUISA STUART, a voluminous English authoress, was born in 1799. In Paris, and afterwards in London, she painted miniatures, and enjoyed the patronage of the Burlett family. From 1852 she received a civil list pension of £75 until her death, which took place at Boulogne, 24th April 1870. Her first production, at least of any note, was *Specimens of the Early Poetry of France* (1835), but it was her bright descriptions of travel in Auvergne, Béarn and the Pyrenees, North Wales, Venice, and the Tyrol, that made her really popular. Her semi-historical novels on Catharine de' Medici, Mary of Burgundy, and Anne of Brittany were read in their day.

Coster, the usual name of LAURENS JANSZON, according to the Dutch the inventor of printing, who was born at Haarlem about the year 1370. He is supposed to have made his great invention between the years 1420 and 1426, to have been sacristan (*Koster*) at Haarlem, and to have died of the plague about 1440. No question has caused more discussion than that between Coster and Gutenberg; an account of this controversy is given under PRINTING. It is unpatriotic not to argue for the native hero, whose relics are exhibited and to whom monuments have been raised. Yet the most thoroughgoing assault on the claims of Coster and of Haarlem, as being founded on local legends, was made in 1870 by a Dutchman, Dr A. van der Linde. See, however, Hessels, *Haarlem, the Birthplace of Printing* (1888).

Costiveness. See CONSTIPATION.

Costmary (i.e. *costus* or aromatic plant of the Virgin Mary), or ALE-COST (*Balsamita vulgaris*), is a herbaceous perennial composite of southern Europe. It was introduced from Italy in 1568, and is cultivated in gardens (as in Britain, and in the United States) for the fragrance of the leaves. The leaves were formerly put into ale and negus, and are still occasionally used by the French in salads.

Costs, the technical name in English law for the expenses incurred in legal proceedings. (In Scotland they are called Expenses, q.v.). Costs are either (1) between solicitor and client—i.e. the charges which a solicitor is entitled to recover from the person employing him as remuneration for professional services; or (2) between party and party—i.e. those which are allowed to the party succeeding in an action against his adversary. As a general rule, costs follow the event, and the costs of the successful party are paid by the loser; but the rule is subject to important exceptions. (1) A party suing or defending *in forma pauperis* does not pay costs, though he is entitled to receive them if successful. (2) In actions in which the plaintiff recovers damages under 10s., he is, in certain cases, not entitled to costs, unless the presiding judge certifies that he ought to have them; and in all other cases, he is not entitled to them, if the presiding judge certifies that he ought not to have them. (3) A plaintiff who might have brought his action in the county court is not entitled to costs

if he sues in the higher courts, and recovers not more than £10 in certain actions, or £20 in others, unless the judge who tries the case certifies that it was proper the action should have been brought in the higher court. (4) A party who is successful in the main, and therefore entitled to the 'general costs,' may be unsuccessful upon some minor point, and therefore bound to pay the costs which belong properly to it. (5) A party who has tendered the amount recovered, and who pays the sum into court, and pleads the tender, is not bound to pay costs. (6) The payment of money into court in the course of an action relieves the party paying from costs of subsequent proceedings, if no greater amount be ultimately recovered.

In suits by and against the crown, the same rules concerning costs apply as in the case of private suits. In administrative proceedings, such as actions for the execution of trusts, or proceedings to ascertain the construction of a will, executors, trustees and others, who have properly or necessarily taken part in the proceedings, are allowed their costs out of the fund or estate involved. When any step in an action is put off at the request of one of the parties, that party is usually required to pay to the other the costs of the particular step. These are called 'costs of the day.' By the Judicature Act, 1875, it was enacted that the costs of all proceedings in the High Court shall be in the discretion of the court; and that where any action is tried by a jury the costs shall follow the event unless for cause shown the judge shall otherwise order.

Costs are taxed (i.e. the items allowed or disallowed) by the officer of the court appointed for the purpose under the name of the taxing-master; and any party may have, if he choose, his own attorney's or solicitor's bill taxed by the same officer.

In criminal cases, the prosecutor's costs may be allowed by the judge, and in that case are paid out of the county rates, the county being reimbursed by the Treasury; and on acquittal of a person indicted who has not been committed or held to bail, the court may order the prosecutor to pay costs to the accused if it think the prosecution unreasonable.

The English doctrine of allowing costs to the successful party generally prevails in the United States. The right to costs, and the rate of costs, is dependent upon statutes which must be strictly construed. The Federal Courts allow costs according to the rates allowed by state law, unless contrary to some act of congress, in which case the latter will prevail as against the state law. By act of congress in 1853 a Fee Bill was established regulating the costs in the Federal Courts. This act, by implication, denies costs to the losing party, which in some cases are allowed by the state laws. The rule of one state as to costs cannot be applied to cases involving contracts of that state litigated in another forum. If the cause is removed from the state to the Federal Courts, the parties are entitled to costs according to the state law prior to removal, and after removal under the act of congress.

Costume. See ANTHROPOLOGY (Vol. I. p. 312), FASHION.

Costus, or COSTUS ARABICUS, an aromatic much esteemed by the ancients, is the dried root of *Aplotaxis auriculata*, a composite plant, and is not derived from the plant *Costus Arabicus*, as was at one time supposed. It is a native of the moist open slopes surrounding the valley of Cashmere. The roots are there burned as incense. They have a strong aromatic pungent odour, and are employed in protecting bales of shawls from moths. It is also

used in India as a hair-wash, as a stimulant in cholera, and as a stimulating ointment.

Cosway, RICHARD, R.A., miniature-painter, was born in 1740, son of the master of Tiverton school in Devonshire. He early displayed a taste for painting, and studied in London under Hudson, in Shipley's school, and in the Royal Academy, of which he became an associate in 1770, and a member in 1771. He painted oil-subjects, aiming at the sweetness and softness of Correggio; but it was in portraiture that he made his mark, and soon his miniatures were 'not only fashionable, but the fashion itself.' Having gained the personal friendship of the Prince of Wales, he was appointed his painter-in-ordinary, and Mrs Fitzherbert and all the beauties of the coterie sat to him. His small female full-lengths with the faces finished in water-colour, though slight in execution, are full of exquisite grace; and his ivory miniatures are also delicate and valuable. Personally Cosway was vain and eccentric. He died 4th July 1821. In 1781 he married MARIA HADFIELD, a skilful musician, also known as an artist; she executed subjects for Boydell's *Shakespeare*, and Macklin's *Poets*. She separated from her husband, and is believed to have died in a convent at Lyons.

Côte-d'Or, a department in the east of France, formed of part of the old province of Burgundy, with an area of 3383 sq. m., and a pop. (1886) of 381,574. The surface is in general rather elevated, and is traversed by a chain of hills forming the connecting link between the Cevennes and the Vosges. A portion of that range, called the Côte-d'Or ('golden slope'), receives its name, which it gives to the department, from the excellence of the Burgundy wines produced on its slopes. Much of the surface is covered with forests. The valleys and plains are fertile, and there is good pasture-land. Côte-d'Or is watered by the Seine, which rises in the north-west, and by several of its affluents; by the Saône, and by the Arroux, a tributary of the Loire. By means of canals it has water-communication with the German Ocean, Mediterranean, English Channel, and Bay of Biscay. The climate is temperate; iron, coal, marble, gypsum, and lithographic stones are found, the first in large quantities. Côte-d'Or is divided into four arrondissements: Beaune, Châtillon-sur-Seine, Dijon, and Semur, and has Dijon for its capital.

Cotentin, THE, the peninsula projecting from the north-west of Normandy into the English Channel, between the Bay of St Michel and the Gulf of Carentan, now forms the northern part of the department of La Manche. It is about 55 miles long and 25 broad. Under the dukes of Normandy, the Cotentin became the seat of numerous powerful barons and rich abbeys. Many of the former followed William the Conqueror to England in 1066, and the names of several of the aristocratic families of England may be traced to humble towns and villages on this peninsula (e.g. Beaumont, Bruce, Carteret, Neville). The Cotentin is highly fertile, and is famous for its herds of fine cattle. The chief town in the peninsula is Cherbourg, though the old capital is Coutances.

Cotes, ROGER, a mathematician, whose remarkable promise was cut short by untimely death, was born at Burbage, near Leicester, July 10, 1682. He had his education at St Paul's School, London, and Trinity College, Cambridge, where he was elected fellow in 1705, and next year, through the influence of Newton, Whiston, and Bentley, Plumian professor of Astronomy and Natural Philosophy. He was elected F.R.S. in 1711, and took orders in 1713. His principal work is the admirable preface explaining the Newtonian philosophy, and answering objections to gravitation, prefixed to the second

edition (1713) of Newton's *Principia*. Various original mathematical papers, tending greatly to the development of logarithms, were edited after his death, which took place 5th June 1716. 'Had Cotes lived,' said Sir Isaac Newton, 'we might have known something.'

Côtes-du-Nord ('northern coasts'), a French department forming part of Brittany, and bounded N. by the English Channel, in which are several small islands belonging to Côtes-du-Nord. Area, 2659 sq. m.; pop. (1872) 622,295; (1886) 628,256. The Menez Mountains, 16 miles broad, and 1115 feet high, cross the department from east to west, and chiefly consist of granite and clay-slate. There are several short but navigable rivers. Though a great portion of the south and the higher plains is occupied by heath and woods, there are also fertile tracts. The cultivation of flax and hemp, with pasturage and iron-mining, supply employment in the hill-districts; while in the sheltered valleys and on the coast-levels grain, pears, apples, &c. are produced. The department is divided into the five arrondissements of St Brieuc, Dinan, Loudéac, Lannion, and Guingamp. The chief town is St Brieuc.

Coteswold, or COTSWOLD HILLS, a range of oolitic limestone hills, running through the middle of Gloucestershire, from Chipping Campden in the N.E., by Cheltenham and Stroud, to near Bath in the S.W. The range is over 50 miles long, with an average height of 500 or 600 feet, and separates the Lower Severn from the sources of the Thames. The highest point is Cleve Hill, 1134 feet. For the Coteswold Games, see ATHLETIC SPORTS.

Cotgrave, RANDLE, author of our earliest French dictionary, but of whose life little is known save that he was a native of Cheshire; was admitted scholar of St John's College, Cambridge, in 1587; became secretary to William Cecil, Lord Burghley; and was alive as late as 1632, in which year he carried the second edition of his dictionary through the press. The first edition had appeared in 1611, and editions revised by James Howell were issued in 1650, 1660, and 1673. Cotgrave's dictionary was a really remarkable book for its time, and is still invaluable to the philologist, not only as a storehouse of older English words, but because it fixes the actual forms of French words at the time when they were first borrowed.

Cöthen. See KÖTHEN.

Cothurnus. See BUSKIN.

Cotillon (Fr., 'petticoat'), the name of a brisk dance, of French origin, performed by eight persons. The quadrille may be regarded as a modification of it.

Cotinga, a genus of Passerine birds, represented by six species in Central and in tropical South America. The family (Cotingidae) to which they belong is often called the Chatterers of South America, though the name Chatterers (q.v.) is by others confined to the Ampelide. They are fruit-eating birds, and the males are very beautifully adorned in blue or violet at the breeding season. See COCK OF THE ROCK.

Cotise, or COST, in Heraldry, one of the diminutives of the Bend (q.v.).

Cotman, JOHN SELL, an artist of the 'Norwich School,' was born 16th May 1782, and educated at Norwich grammar-school, till, about 1798, he went up to London to study art, and there made Turner's acquaintance. In 1807 he returned to his native city, where he taught drawing and published etchings and engravings of local architecture, brasses, &c. In 1834 he obtained, through Turner, the post of drawing-master in King's College, London, but his later years were clouded by much

suffering. He died 24th July 1842. Cotman's fame as a water-colour landscapist has grown steadily; indeed Mr Cosmo Monkhouse opines that 'taken altogether he was the most gifted of the Norwich School, wider in range, a finer draughtsman, and of more refined and cultivated individuality, than "Old Crome."' His second son, Joseph John Cotman (1814-78), was also a landscape-painter.

Cotoneaster, a genus of Rosaceæ, sub-order Pomæe, closely allied to the hawthorn and medlar. The species are shrubs or small trees, some evergreen; with simple entire leaves, more or less woolly beneath; small flowers in lateral cymes; and small, unpalatable, but bright-coloured fruit, persistent in winter. *C. vulgaris* (said to be found wild in a single locality in Wales) and other species are common mountain plants of central Europe and Asia, but have been largely introduced as ornamental shrubs, the evergreen species (*C. rotundifolia*, &c.) being especially used for covering walls and rockwork.

Cotopaxi, the loftiest active volcano in the world, is in Ecuador, in the eastern chain of the Andes, and about 50 miles S. of the equator. Humboldt gave the height at 18,880 feet; Reiss, the first to ascend it (in 1872), at 19,500 feet; Whymper, who ascended in 1880 to the edge of the crater, at 19,550 feet above the sea. The valley at its foot, however, is itself 9000 feet high. The upper part of Cotopaxi, a perfect cone of 4400 feet, is entirely covered with snow, save that the verge of the crater is a bare parapet of rock. Below the snow is a well-marked barren belt covered with lichens and shrubs, below which again is forest. Smoke issues from the summit; sounds as of explosions are occasionally heard; and above, a fiery glow is often visible by night. Lava rarely flows even during eruptions, but flame, smoke, and immense volumes of ashes are then ejected; and when the heat melts large masses of the snow lying on the sides, destructive floods are occasioned in the valleys beneath. The first eruption recorded was in 1533. Others followed in 1698, 1743, 1744, and 1768, the most terrible of all. On the latter occasion ashes were carried 130 miles distance, and thickly covered an extensive area. Cotopaxi was quiet till 1851. In 1854, 1855, and 1856 there were again eruptions of more or less violence.

Cotrone, a fortified town of Italy, 35 miles NE. of Catanzaro by rail, built on a point of land projecting into the sea at the mouth of the Esaro, north of Cape Nau or Colonne. Pop. 9649.

Cotta, a publishing-house established at Tübingen in 1640, and still one of the most flourishing in Germany. The family came originally from Italy. Its most prominent members have been (1) Johann Friedrich (1701-79), a learned writer and theological professor at Tübingen, Göttingen, and Jena; (2) his grandson, Johann Friedrich, Freiherr Cotta von Cottendorf, born at Stuttgart in 1764, educated at Tübingen, and for some time an advocate. In 1787 he undertook the family business; and in 1795 established the famous *Horen*, a literary journal, under the editorship of Schiller, with the friendly co-operation of Goethe and Herder. Already in 1793 he had sketched out the plan for the *Allgemeine Zeitung*, which has appeared since 1798. The *Almanach für Damen* (1798) and other periodicals were no less successful. Cotta now began likewise to publish the works of Schiller, Goethe, Herder, Fichte, Schelling, Jean Paul, Tieck, Voss, the Humboldts, &c., establishing thereby a claim to the gratitude of the wide literary world. In the seventy years ending in 1864, the house had paid to Schiller and his heirs no less a sum than 528,966 marks, to Goethe and his heirs

in the same period, 865,554 marks. In 1810 he changed his residence to Stuttgart, and in 1824 introduced the first steam printing-press into Bavaria. He died 29th December 1832. In the diet of Württemberg, and afterwards as president of the Second Chamber, he was ever the fearless defender of constitutional rights; he was, too, the first Württemberg proprietor who abolished servitude on his estates. He was succeeded by his son, Georg (1796-1863); and he by his son Georg Astolf (1833-76).

Cottage, a small dwelling-house, especially of labourers, varying greatly in size, appearance, and comfort. Since 1860 especially, public attention has been called to the deplorable state of the cottages in many parts of Great Britain, and the desire to secure their improvement has led to the publication of many works on Cottage Architecture, including those of Birch (1872), Young (1872), Bicknell (1877), Shand (1878), Bruce (1886), and Menzies (1886).

Cottbus, or KOTTBUS, a town of Prussia, in the province of Brandenburg, situated on the Spree, 71 miles SE. of Berlin by rail. It is an important railway junction and a busy mercantile town, with manufactures of woollen cloth, carpets, hats, linen, jute, leather, and tobacco. Pop. (1875) 22,642; (1885) 28,249.

Cotters. See CROFTERS.

Cottin, SOPHIE (née Ristaud), French authoress, born at Tonneins, in the department of Lot-et-Garonne, in 1773, married at seventeen a Parisian banker, who left her a childless widow at twenty. For comfort she turned to letters, wrote verses and a lengthy history, and in fiction won unfading laurels. She had already written *Claire d'Albe* (1799), *Matruina* (1800), *Amélie Mansfield* (1803), and *Mathilde* (1805), when in 1806 she wrote *Elisabeth, ou les Exilés de Sibérie*, a story stamped with such real unsought pathos that it has been translated into most European languages. Madame Cottin died 25th August 1807.

Cottle, JOSEPH, bookseller and author, born in 1770, was well read in English literature when he started business in Bristol in 1791. He took kindly to Coleridge and Southey, to whom he was introduced by Robert Lovell, and offered them each 30 guineas for their poems; and in addition 50 guineas for Southey's *Joan of Arc*, with 1½ guineas to Coleridge for every additional 100 lines of poetry he might write. The poems thus arranged for appeared in 1796. Cottle also became responsible in a business, and partly in a pecuniary, sense for Coleridge's *Watchman*; and an introduction to Wordsworth led to his publication of the afterwards famous *Lyrical Ballads* (1798). Cottle was intrusted with the delicate duty of handing over De Quincey's generous donation of £300 to Coleridge, to whom he also addressed some serious expostulations as to his indulgence in opium, which drew replies from the poet. Cottle's injudicious and unmerciful exposure of Coleridge in his interesting but sometimes inaccurate *Early Recollections* (1837) has been condemned. He wrote several volumes of verse; the fourth edition of his *Malvern Hills* (1829) contains several prose essays. He retired from business in 1799, and died 7th June 1853.—His elder brother, AMOS SIMON COTTLE (1768-1800), educated at Bristol and Cambridge, wrote various works, including *Icelandic Poetry* (1797), which contains a poetical address to him from Southey.

Cotton, an important vegetable fibre, extensively cultivated in various parts of the globe within the 35th parallels of latitude.

(1) *Botanical and Commercial Classifications*.—Cotton is the produce of all the species of the

genus *Gossypium*, which belongs to the natural order Malvaceae, and is thus allied to Mallow, Hollyhock, Hibiscus, &c., the general resemblance to which is very apparent both in the foliage and flowers. The species are partly shrubs, partly herbaceous, and either perennial or annual; they are natives of the tropical parts of Asia, Africa, and America, but their cultivation has extended far into the temperate zones. They all have leaves with three to five lobes, which in a very young state are often sprinkled with black points, and rather large flowers, which are mostly yellow, but sometimes in whole or in part purple; the flowers very soon fall off; they grow singly from the axils of the leaves, and are surrounded at the base by three large, heart-shaped, cut or toothed, involucre leaves or bracts, partially growing together as one. The fruit is a 3-5-celled capsule, springing open when ripe by 3-5 valves, and containing numerous seeds enveloped in cotton, which is generally white, but sometimes yellow, and issues elastically from the capsule after it has burst open. The fibres are long cylindrico-spiral tubes of from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in breadth, which when platted adhere firmly together. The wool is also very susceptible of dyeing. The figure shows the manner in which the cotton escapes from the capsule. Some

Cotton (*Gossypium Barbardense*):

a, ripe capsule after dehiscence; b, a seed; c, the same deprived of its hairs. (From Bentley & Trimen.)

of the kinds have the flowers larger in proportion, and the leaves divided into more numerous and much deeper and narrower lobes, but the general appearance of all is very similar.

Difference of opinion exists among botanists as to the number of distinct species, and there are very many varieties in cultivation, the number of which, through climatic influences and other causes, is continually increasing; but there are certain leading peculiarities on account of which some botanists and planters reduce all, at least of the cultivated kinds, to four primary species—viz. (1) *Gossypium Barbardense*; (2) *G. herbaceum* or *indicum*; (3) *G. peruvianum*; and (4) *G. arboreum*. The produce of the first species is the most valuable. The beautiful long-stapled ($1\frac{1}{2}$ to 2 $\frac{1}{4}$ inches) silky wool known as 'Sea Island' is a variety, and is grown exclusively upon the islands and a portion of the mainland of Georgia, South Carolina, and Florida; the saline ingredients of the soil and atmosphere being indispensable elements of the growth. The plant, 6 to 12 feet

in height, bears a yellow flower, and the seeds are small, black, and quite smooth, and the wool is easily separated therefrom; but when sown far inland, away from the saline influences of the coast, the seeds increase in size, and become covered with innumerable short hairs. A large percentage of the crops raised in Alabama, Louisiana, Mississippi, Texas, &c., are also varieties of this species, though, owing to climatic influences, the plant is smaller (4 to 6 feet in height), and the wool is shorter in staple ($\frac{3}{4}$ to 1 $\frac{1}{4}$ inch), and less easily separated from the seeds than Sea Island. In 1888 the commercial value of the latter kind varied from 10d. to 21d. per lb., rare specimens sometimes realising 2s. 6d. to 3s. per lb. The better descriptions of Egyptian cotton belong to *G. Barbardense*, and bring 9d. to 18d. per lb. in the Liverpool market (staple 1 to 1 $\frac{1}{4}$ inch). The short-staple varieties, known as New Orleans, Mobile, Uplands, &c., sell at from 4d. to 7d., extra qualities sometimes bringing 9d. to 10d. per lb. *G. herbaceum* is found in India, China, Africa, &c. The principal commercial varieties are those known as Surat, Madras, Bengal, &c. It is a small shrubby plant (2 to 4 feet high), bears a yellow flower, the seeds are covered with short grayish down, and the staple produced, though not long ($\frac{3}{4}$ to 1 inch), is very fine. Its price varies from 3d. to 5 $\frac{1}{2}$ d. per lb. The cotton known as nankeen is thought to belong to this species. *G. herbaceum* can be profitably cultivated in colder countries than any other species of cotton-plant. The third species (*G. peruvianum*) is a native of South America, and the 'green seed' cotton of the United States appears to be a variety. The stem reaches 10 to 15 feet in height, the flowers are yellow, and the capsules contain eight or ten black seeds firmly attached together in a cone-like mass. The wool is long (1 to 1 $\frac{1}{4}$ inch) and strong-stapled, and in value stands next in order to Sea Island and Egyptian. Pernambuco, Maranhão, Bahia, Maceio, and Peruvian are varieties which sell in Liverpool at from 5 $\frac{1}{2}$ d. to 6 $\frac{1}{2}$ d.; extra qualities of Peruvian bring 6 $\frac{1}{2}$ d. to 8d., and Sea Island Peruvian is worth 9 $\frac{1}{2}$ d. to 12d. per lb. *G. arboreum* is found in India, China, &c., and, as its name imports, is a large tree-like plant. It bears a red flower, and produces a fine yellowish-white wool. Varieties of it have been long cultivated in the United States, and with the requisite soil and climate, are said to produce a wool somewhat resembling Sea Island.

The finer kinds of yarn are spun from Sea Island and long-stapled Egyptian, and from them are fabricated our muslins, laces, &c. From Brazil and the better classes of short-stapled American come our cambrics, calicoes, shirtings, sheetings, &c., and from the inferior qualities of American and Surat are spun the coarse yarns required for fustians and other heavy fabrics. Yorkshire broadcloths are sometimes half cotton. From warps of cotton, and wefts of wool or worsted, are formed varieties of Orleans cloths, Coburgs, mousselines de laine, &c. There are also fabrics composed of silk and cotton, linen and cotton, alpaca and cotton, &c.

(2) *Cultivation*.—The plant is a very delicate organism, and requires a peculiar soil and climate for its due development. The method of cultivation is much the same in the various countries where the fibre is grown; but the most perfect system is that which obtains in the United States of America. Although the plant is not, strictly speaking, an annual, it is found more profitable to destroy the shrub, after the crop is gathered, and sow new seed every year. The preparation of the land takes place during the winter months. After the ground has been thoroughly ploughed, and as soon as all symptoms of frost have disappeared, the soil is laid

off into rows varying in width from 3 to 4 feet, according to the situation and quality of the soil. The seed is then sown along the centre of the beds in a straight furrow made with a small plough or opener; but in some plantations the seed is sown in holes from 12 to 18 inches apart. The sowing commences in March, and generally continues through April; but sometimes, owing to late spring frosts, the planting is prolonged to May. The young shoot appears above ground in about eight to ten days, and is then and subsequently weeded and thinned. Blooming takes place about the beginning of June—in early seasons, towards the latter end of May; the average date is about June 5. For ploughing, the planter requires just sufficient rain to give the soil a moist and spongy texture. During the early stages of its growth, the crop flourishes best with a warm steamy sort of weather, with an occasional shower until blooming; too much rain being productive of weeds and wool at the expense of wool, whilst a severe drought produces a stunted plant, forced into too early maturity, and resulting in a small and light-stapled crop. A great deal, however, depends upon the position of the plantation; lands situated in hilly or upland districts obviously requiring more moisture than those lying in the plains and river-bottoms. From the date of blooming to the close of the picking season, warm dry weather is essential. Picking generally commences in August, occasionally in July, and continues until the occurrence of frost—about the end of October or beginning of November—puts a stop to the further growth of the plant. Occasionally, in the absence of a killing frost, picking extends to December or January, and even into February, but the cotton is inferior in grade and quality. All the available hands of the plantation, young and old, are called into full employment during the harvest. The cotton is gathered into baskets or bags suspended from the shoulders of the pickers, and when the crop has been secured, it is spread out and dried, and then separated from the seeds.

The latter process was formerly performed by hand—a tedious operation, by which one hand could clean only a pound or so a day; but since the invention of the saw-gin by Eli Whitney in 1793, the process of cleaning has been both rapid and effectual. This machine is composed of a hopper, having one side formed of strong parallel wires placed so close together as to exclude the passage of the seeds from within. The wool is dragged through the apertures by means of circular saws attached to a large roller, and made to revolve between the wires, the seeds sinking to the bottom of the hopper. This process is adopted only in cleaning the short-stapled varieties of American cotton, the wool of which adheres so firmly to the seeds as to require a considerable amount of force to separate them. The Sea Island variety is cleaned by being passed through two small rollers which revolve in opposite directions, and easily throw off the hard smooth seeds. In India, though the saw and other machine-gins have been introduced in some districts (notably the Macarthy-gin in Broach, and the saw-gin in Dharwar), the wool is mostly cleaned by means of the primitive roller. Prior to the American war the roller-gin was in exclusive use in Egypt and the Brazils, but the cotton famine led to the invention of the Macarthy-gin (which in principle is an improved roller-gin), and to its introduction into Egypt, and to the adoption of the saw-gin by the planters of Brazil; the effect in both cases being a considerable extension of the culture. The cotton cleaned by the roller-gin, being uninjured thereby in staple, realises the better price; but the deterioration caused by the saw-gin is compensated for by the

greatly increased quantity cleaned: the latter turning out four or five times as much wool as the former in an equal space of time.

In *India*, throughout the greater portion of the Bombay Presidency, the North-west Provinces, the Central Provinces, and the Berars, sowing generally takes place between the middle of June and the middle of July, but in Dharwar and other southern districts of Bombay, and in the Madras Presidency, not until August or September—in some places later still. In the first-named districts picking commences in November, but in some portions not until January or February, and in Madras not until March or April. The extension of the railway system brings cotton which formerly went to other ports to Bombay (q.v.), and 80 per cent. of the total export from India is now from that port, while the bulk of the shipments takes place in the first six months of the year. In *Egypt* sowing commences in March or April, and picking in October—continuing until January. The busiest export months are November to February. In *Brazil* planting takes place as early as January or as late as May, according to district, and picking six months later. The chief shipping months are October to May.

(3) *Production and Distribution.*—The oldest cotton-producing country is India, in which empire the plant has been grown and manufactured from time immemorial. The first notice of it in connection with China dates no further back than the 11th century, but it is exceedingly probable that the plant was cultivated there long prior to that period, as cotton fabrics were known in China before the Christian era. Early mention is made of it in the annals of Egypt, and it is believed to have a high antiquity in all parts of Africa. It has for many centuries been produced in Asia Minor, in several of the Mediterranean islands, in Greece, and Southern Italy. In the western world, it was found by Columbus in the West Indies, and in Mexico and South America by his immediate successors, but was not so extensively cultivated as in the East; though during the past half-century the culture there has outstripped, both in quantity and quality, the produce of the Old World. Down to the commencement of the 19th century the cotton consumers of Europe were dependent upon the East and West Indies and the Levant for their raw material; but the inventive genius, superior farming, and greater energy of the planters of the southern states of America had, prior to the civil war, almost secured the monopoly of supplying the manufactures of Great Britain and the European continent with this valuable fibre. The following table gives at a glance the movements for a century back. The figures represent the annual imports into Great Britain from the chief sources of supply, in bales of the uniform weight of 400 lb. each, in quinquennial averages, except that the last column is based on the average imports for two years only:

	1786-90.	1816-20.	1846-50.	1876-80.	1886-87.
British West.....	45,000	23,800	1,910	1,670	660
Indies.....	13,000	1,030	31,310	402,190	435,590
Mediterranean.....	6,000	55,760	57,860	85,330	126,040
Brazil.....	500	98,710	196,140	519,800	601,710
East Indies.....	100	166,310	1,297,230	2,589,070	3,186,790
United States.....	..	10,970	2,870	51,710	32,310
Sundries.....
Total.....	63,000	351,580	1,587,320	3,640,770	4,883,100

At the close of the 18th century the *British West Indies* supplied 70 per cent. of the cotton imported into Great Britain, but owing to the competition occasioned by the rapid expansion of the culture in the southern states of the American Union, the imports gradually decreased; the planters finding it more profitable to employ their labour and capital

in the production of sugar and other articles. In the thirty years ended 1820, the quantity fell off nearly 50 per cent., while the proportion of West Indian in the total imports from all countries fell from 70 per cent. down to barely 7 per cent. Thirty years later it was only about one-tenth of 1 per cent. During the American war there was an increase to about 10,000 bales. After the close of the war the import fell rapidly away. In 1870 it was about 6000 bales; in 1886, only 150 bales; in 1887, 1160 bales.

After the West Indies, the chief sources of supply a century ago were the countries bordering on the *Mediterranean*—Asia Minor, Cyprus, &c. The large increase in the imports from the Mediterranean since 1820 is due to the development of the cotton industry in Egypt. The cotton-plant has been in existence in Egypt from time immemorial, but the cotton known as Egyptian is the product of an exotic plant introduced by the French about the beginning of the present century from the Isle de Bourbon, into which it had been introduced from Barbadoes. M. Jumelle, a French mechanician, saw the plant in a garden at Cairo in 1821, and at his suggestion Mehemet Ali gave instructions that as much seed as could be obtained should be planted in Lower Egypt. The first crop produced about 1000 cantars of 93 lb. net, and with the seed from this about 35,000 cantars were raised in the succeeding season (1822-23), say about 8000 bales of 400 lb. In 1824-25 the crop reached 228,000 cantars, or 53,000 bales of 400 lb. During the subsequent ten years the culture was more or less interrupted, owing to political disturbances, and at times seriously reduced in consequence of the withdrawal of a large number of labourers to carry on the wars of the Pasha in the Soudan, Syria, &c. From 1867 to 1879-80, with occasional fluctuations owing to unfavourable seasons, there was a gradual increase, until the total reached 3,168,000 cantars, since which but little progress has been made, partly in consequence of the fall in prices, and partly owing to the slower increase in the demand for long-stapled cotton, compared with that of the shorter stapled growth of America. In 1884-85 (a good year) the area planted was 912,000 English acres, and the product 335,000,000 lb.; in 1887-88 (a poor year) 1,060,000 acres produced 282,700,000 lb.

There are several varieties of cotton produced, but they are all from one species. Out of a total crop of 3,000,000 cantars, about 2,500,000 consist of Asimouni and similar varieties. The staple is good and the colour brown. About 100,000 cantars consist of Gallini, which is long and silky in staple, and competes with Sea Island. The remaining 400,000 cantars will consist of white cotton similar in staple to the brown, and not unlike extra-stapled Orleans. Gallini was (1888) quoted 8½d. to 11d. per lb., brown 3½d. to 8d. per lb., and white 5½d. to 7d. per lb.; against 11½d. to 21d. per lb. for Sea Island, and 4½d. to 6d. for the current grades of Orleans.

In 1860 the total import of cotton into Europe from Turkey and other Mediterranean countries, except Egypt, was only 21,000 bales of 400 lb. In 1865 it rose to 239,000 bales, fell to 129,000 in 1867, and rose to 207,000 in 1869. Since 1880 it has fluctuated between 24,000 and 50,000 bales of 400 lb. During the height of the cotton famine (1863-65), Italy and Greece produced 100,000 to 120,000 bales of 400 lb., a large part of which is included in the imports of these years, but they do not now produce more than 10,000 bales.

The first import from Brazil arrived in 1781. In the five years 1786-90 the receipts averaged 5000 bales of 400 lb. In thirty years they were increased tenfold; but with a plentiful supply from the United States there was little further progress

during the thirty years ended 1850. The cotton famine led to an extensive expansion in production. In 1879 there had been a reduction to 47,000 bales; but by 1887 there was a recovery to 207,000 bales. From other places in *Central and South America* the imports into Great Britain in the five years (1883-87) from Peru fluctuated from 3,050,000 to 7,411,000 lb.; from Chili, 284,000 to 1,560,000 lb.; from Venezuela and other portions of South America, 310,000 to 1,549,000 lb. Mexico uses about 180,000 bales of 400 lb., of which 130,000 bales are home-grown, and 50,000 imported from the United States (44,000 bales of 456 lb.).

In their search for the increased supply of cotton requisite to meet the wants of the rapidly growing industry of a hundred years ago, the spinners of Lancashire naturally directed their eyes towards India, where the plant had been cultivated and the manufacture carried on from time immemorial; and at their suggestion the East India Company imported a small parcel in 1789—about 5000 lb., which was followed by about 400,000 lb. in 1790. The venture, however, was not satisfactory, and in 1791 the arrivals fell to about 3000 lb., and in 1792 to nothing. But high prices brought renewed supplies, and in 1880 the imports reached 6,630,000 lb., or about 16,000 bales of 400 lb. In 1790 West India cotton was selling at 12d. to 21d. per lb., but in 1798 the quotation ranged from 25d. to 40d. per lb., in which year American was quoted at 22d. to 45d. per lb. Thence to the end of the Napoleonic wars there were very wide fluctuations (see next page). These variations in prices led to considerable fluctuations in the imports of cotton from India, but the general tendency was in the direction of increased figures; the arrivals in 1806-10 averaged 25,000 bales of 400 lb. per annum; in 1816-20 they rose to nearly 94,000 bales, but in 1826-30 fell to 55,000 bales. The large import between 1816 and 1820 became so unsaleable that 10,000 bales (Bengals) were shipped from London to China! Since 1830 the imports have been large or small, according to the outturn of the crops in the United States. This was especially the case prior to the American war, but the impetus given to the industry by the cotton famine incidental to that event, led to such greatly improved methods of ginning and handling the crop, that the supply from India is no longer merely supplementary to that from America. The quality is greatly superior to the imports of a quarter of a century ago, and of recent years the consumption in Europe has averaged 1,500,000 bales, against only 500,000 in 1860, and only about 200,000 in 1850. The total crop of India is about 2,600,000 bales of 400 lb., of which 1,000,000 bales are consumed in India, and 1,600,000 bales exported. Considerable changes have taken place in the distribution of the crop during the past quarter of a century. Prior to the opening of the Suez Canal (November 1869), the bulk of the cotton received into Europe from India came in the first place to England. Half the imports were also spun in Great Britain; but since the opening of the canal, continental spinners have taken the bulk of their requirements direct, while the quantity consumed in England is only about one-sixth of the total consumption of Europe. These changes are set forth in the following account of the imports into Europe, and the deliveries for consumption in the years named in 1000's of bales as imported (360 lb. to 393 lb.):

	IMPORT—direct.			CONSUMPTION.		
	Great Britain.	Continent.	Total.	Great Britain.	Continent.	Total.
1861	986	13	999	343	423	770
1863	1452	193	1645	801	859	1660
1872	1288	408	1696	687	942	1629
1882	1052	721	1773	466	1138	1598
1887	668	934	1602	259	1208	1527

The variations in the two totals arise from varia-

tions in the stocks at the end of the year. The consumption in India in 1887 was about 1,000,000 bales, including about 700,000 to 750,000 used by mills containing machinery imported from England, and built and worked as in Lancashire.

The first import of cotton from the *United States* took place in 1784, and consisted of eight bags weighing about 1200 lb. Occasional small shipments had been received from the American colonies prior to this date, but they consisted chiefly of West Indian produce transhipped, and as the colonies were now independent, the eight bags just mentioned were detained by one of the customs' officials, on the ground that as West Indian produce it was a breach of the then existing navigation laws to import them in a *foreign* vessel. But the parcel was liberated on proof being forthcoming that the cotton was really the produce of the United States. In 1791 about 189,000 lb. were exported, but in 1792 only 138,000 lb. In 1793 Eli Whitney invented the saw-gin, and the cultivation of the plant increased so rapidly that the exports bounded from less than 500,000 lb. in 1793 to over 6,000,000 lb. in 1795, to more than 9,000,000 in 1798, and to 20,000,000 lb. in 1801, or in eight years from about 1200 bales of 400 lb. to 50,000 bales. What has since taken place is shown at a glance in the following table, which gives the crops of the various states, the total quantity exported, and the balance left for consumption and stock in various years from 1800 to 1887, in 1000's of bales of the uniform weight of 400 lb.:

	1800.	1820.	1840.	1860.	1870.	1880.	1887.

Consumed....	40	80	340	968	996	1920	2295

The Virginian figures for 1880 and 1887 include some cotton raised in Missouri. Alabama was admitted into the Union in 1819, Mississippi in 1817, Louisiana in 1811 (purchased from France in 1803), Florida in 1845 (ceded by Spain in 1819), Arkansas in 1836, and Texas in 1845. The reduced crop of 1870 shows the extent to which the agricultural industry of the South had been thrown back by the war of 1861-65. Even in 1887 the crops of several of the states were still below those of 1860, in consequence of the transference of labour farther west to Texas and Arkansas. Of the total increase of 1,083,000 in 1880 over 1860, 791,000 belonged to these two states, which also figure for 1,756,000 bales out of the 2,038,000 increase in 1887 over 1860.

As the crops increased prices declined, especially as the cost of production was gradually reduced by improved methods of cultivation and cleaning. The cost to consumers in Europe was also diminished by cheapened freights and carriage, and by other economies brought about by the competition amongst the various middlemen who had the handling of the crop from the plantations to the spindles. At the opening of the century the average price of middling American was about 18d. per lb. In 1803 it fell to 12d., but in 1814 it stood at 30d., and during the year was as high as 36d., owing to the partial cessation of imports caused by

the war. Thence (with fluctuations) the tendency was downwards until 1829, in which year the average was only 5½d. Production had outrun consumption, and the stock of American cotton in Great Britain at the end of 1827 was equal to thirty-eight weeks' requirements. The low prices retarded production and stimulated consumption, and by 1835 the stock of American was reduced to only ten weeks' requirements, while the average price advanced to 10½d. per lb. During the subsequent ten years, production again overtook consumption, and in 1845 the stock of American in England was equal to thirty-three weeks' requirements, while the average price was only 4½d., after having in the course of the year touched 3½d. per lb. These prices were repeated in 1848 owing to disturbed politics. In 1850 there was a rebound to 7d., but thence to 1852 a fall to 5½d., owing to increased crops. Thence to 1860 the average price fluctuated between 5½d. and 7½d., ending in 6½d. The war between North and South cut off supplies, and prices rapidly advanced, until in 1864 the average reached 27½d., while as high as 31½d. had been touched in the course of the year. In 1865, with peace, the average fell to 19d., and it was thought that values would rapidly decline to the ante-war level. But the war, and the abolition of slavery incidental to it, had so thoroughly disorganised the industrial system of the South, and so completely impoverished the planters, that the average price of 1860 (6½d.) was not touched until 1876, while the crop of 1860 (4,824,000 bales), though almost repeated in 1876 (4,660,000 bales), was not actually exceeded until 1879 (5,073,000 bales). Between 1876 and 1879 the average price ranged from 6½d. to 6¾d. Since then the tendency has been downwards. In 1886 it fell to 5½d., but in 1887 rose to 5½d. The decline in prices which has taken place within the past ten years has been due mainly to reduced cost of production, to diminished land and ocean freights, and to lessened intermediate charges brought about by the elimination of unnecessary middlemen, though part of the fall is, no doubt, traceable to the currency changes, which have affected values in general.

The variations in the outturn of the crops were due to climatic causes. In 1881-82 the plant suffered from severe drought; 1882-83 was a phenomenally perfect season; 1883-85 were drought seasons; 1885-87 were average seasons; 1887-88 was better than an average, but not so good as that of 1882-83. The 6,514,000 bales produced in 1886-87 weighed 2,970,384,000 lb. net, equal to 7,425,000 bales of 400 lb., as given in the table above, containing particulars of the crops of each state separately.

Particulars of the extent of land planted, and of the weight of cotton produced, are given in the following table:

Season.	Area Planted, acres.	Pounds of Cotton. Total.	Per acre.
1881-82	16,711,000	2,424,456,000	145.0
1882-83	16,277,000	3,218,320,000	197.5
1883-84	16,778,000	2,582,728,000	153.9
1884-85	17,426,000	2,556,719,000	146.6
1885-86	18,379,000	2,986,250,000	162.1
1886-87	18,632,000	2,970,384,000	159.4
1887-88	18,700,000	3,192,735,000	169.9

The production per acre varies considerably—from less than 100 lb. per acre in the poorest upland soils to 500 lb. per acre in the rich bottom lands of the south-west. The average production per season, for the entire cotton-growing region, has for the past seven years ranged from 145 to 197½ lb. per acre. The average for the seven seasons was 162 lb., or about one-third of a bale. The crop of 1886-87 was worth at the plantations about £51,800,000, according to the annual report of the Department of Agriculture.

The following is an account of the imports of

cotton into all Europe (in bales of the uniform weight of 400 lb.) in and since 1860 :

	United States.	Brazil.	Egypt.	Turkey, &c.	W. Indies, &c.	E. Indies, &c.	China and Japan.	Total.	Average Riddling Upland.
1860	4058	48	135	21	23	552		4837	6½
1861	3075	46	124	36	18	940		4248	8½
1862	102	65	182	68	20	1010		1439	17½
1863	163	67	294	127	36	1179	81	1947	23½
1864	241	127	427	158	39	1374	230	2635	27½
1865	522	150	540	239	84	1231	85	2860	19
1866	1555	222	279	161	77	1706	15	4015	15½
1867	1059	220	305	120	103	1389	1	3806	10½
1868	1946	309	355	145	85	1476		4316	10½
1869	1583	281	353	207	92	1578		4094	12½
1870	2345	217	379	130	79	1057		4213	9½
1871	3409	281	366	119	130	1384		5719	8½
1872	2234	377	489	138	121	1526		4836	10½
1873	2908	243	484	143	105	1155		5038	9
1874	3177	252	532	93	98	1317		5169	8
1875	3112	216	552	88	69	1420		5487	7½
1876	3461	169	749	89	55	1134		5657	6½
1877	3103	149	625	89	37	930		4993	6½
1878	3908	68	458	51	73	813		5318	6½
1879	4329	47	616	31	42	868		5933	6½
1880	4520	78	583	24	33	1074		6312	6½
1881	4815	135	726	26	33	1098		6843	6½
1882	4457	166	597	38	32	1677		6967	6½

1885	4371	99	808	65	29	943		6315	5½
1886	5025	96	709	46	30	1306		7212	5½
1887	5320	208	734	41	28	1575		7915	5½

Of the total quantity of cotton imported into Europe in 1860, no less than 83·9 per cent. came from the United States. For a number of years it had averaged about 75 per cent. This virtual dependence of a vast industrial system upon one source of supply for the raw material necessary to keep its labour and machinery fully employed, had long been regarded with considerable anxiety; the more so as it was known that sooner or later a great crisis would, for a period of more or less duration, dislocate the agricultural industry of the South; but all attempts to escape from so undesirable a state of things were frustrated by the one important fact that no other cotton-producing country had been able successfully to compete with America in either quality or price. The war, by raising values to a famine level, led to a largely increased production of cotton in India, Egypt, South America, &c.; but even after the conflict had lasted four years, scarcely half of the decrease in the imports from the South had been made up by increased receipts from all the world besides. The average import from America in the two years 1860-61 was 3,566,000 bales of 400 lb., but in 1864-65 only 381,000, showing a loss of 3,185,000 bales. The average import from all other sources in 1860-61 was 976,000, and in 1864-65, 2,366,000, showing a gain of only 1,390,000 bales, or barely 46 per cent. of the deficit in the supply from the States. After peace had been restored, and cotton-planting at the South had been resumed, prices rapidly declined; but for ten years after the war they remained considerably above the rates current prior to 1861, and yet the import of cotton into Europe from countries other than America never exceeded 2,651,000 bales of 400 lb. (1872), while the annual average for the ten years ended 1875 was only 2,309,000 bales, against 2,366,000 in 1864-65. Between 1875 and 1880, with a fall to ante-war prices, the imports from countries other than the United States fell to an average of only 1,767,000 bales, while those from the South rose to 3,875,000 bales, and in 1881 the receipts from America represented 70 per cent of the total imports into Europe. In 1886 the proportion was 60½ per cent., and in 1887, 67 per cent.

Prior to the American war, very exaggerated notions prevailed respecting the quantity of cotton

produced in India: the current estimates being 5,000,000 to 6,000,000 bales of American weight (450 lb.), while some computations ran as high as 10,000,000 bales. But the fact that famine prices attracted to Europe only about a million and a quarter bales per annum in the three years ended 1865, proved that the crop was much smaller than had previously been calculated upon, and the investigations and inquiries made by the government in 1867-68 showed that the annual yield could not at any time have exceeded 2½ to 2½ million bales of 400 lb. The consumption of cotton goods in India is about 2½ lb. per head per annum, or a total of 650,000,000 lb. for a population of 260,000,000. In the three years ended 1887, the weight of goods and yarn imported into India averaged 390,000,000 lb., of which about 70,000,000 lb. were re-exported, leaving 320,000,000 lb. for consumption. The consumption of native-made goods would therefore be about 330,000,000 lb. This item, added to 90,000,000 lb. Indian yarn and goods exported, and 550,000,000 raw cotton exported, gives a total of 970,000,000 lb. as the probable extent of the cotton crop in 1885-87. This calculation cannot be far astray inasmuch as the area under cotton did not exceed 14,000,000 acres, which at 70 lb. per acre (the estimated average yield) gives a total of 980,000,000 lb., or 2,450,000 bales of 400 lb.

No cotton was received from China (except occasional small samples) until prices had risen to about 2s. per lb., and even this extravagant figure brought to Europe only 380,000 bales of 400 lb. during the four years of the famine, a proof that the cotton crop of China is much smaller than even that of India. Assuming the consumption of cotton fabrics to be at the rate of 2½ lb. per head, and allowing for yarns, goods, and raw cotton imported, the crop cannot exceed 1,500,000 bales of 400 lb. A similar calculation for Japan, Java, &c., gives a crop of 130,000 bales.

Small imports of cotton are received every year from Africa, but they rarely exceed a few hundred bales. The plant is cultivated throughout the continent, and if the *per capita* consumption averages only half that in India and China, the 200,000,000 inhabitants will require 250,000,000 lb. of cotton fabrics; but as 100,000,000 lb. of goods are imported, the crop required would be only 150,000,000 lb., or 375,000 bales of 400 lb.

The crops of the various countries and districts of the world in 1887 were, as nearly as can be ascertained, as follows (in bales of the uniform weight of 400 lb.):

	Bales.	Per Cent.
United States of America	7,425,000	55·81
South America, West Indies, &c.	430,000	3·24
East Indies	2,500,000	18·79
China	1,500,000	11·27
Japan, &c.	130,000	0·98
Turkey and Persia	120,000	0·90
Asiatic Russia	100,000	0·75
Egypt	713,000	5·35
Africa (except Egypt)	375,000	2·82
Italy and Greece	10,000	0·07
Australia, Fiji, &c.	2,900	0·02

Total for the world 13,305,000 100·00

It will be observed that the United States produce more than half the cotton grown in the world, although they only commenced the business about one hundred years since.

(4) *Consumption.*—*Great Britain.*—It is not possible to ascertain with certainty the first beginnings of the trade in Europe. It existed in Spain in the 10th century, and no doubt quite as early in Italy and Greece. The first recorded import of cotton into England was in the 13th century, and quite as early imports took place into France through Marseilles. The first mention of the industry in connection with Germany, Holland, and Switzer-

land was in the 16th century, and in Russia in the 18th. But until the close of the last century, the cotton used was either for candle wicks or for mixture with flax or wool. The first piece of British-made calico—i.e. a fabric all cotton—was produced in 1783. Prior to that date cotton-yarn had been used for weft only, the warp being supplied by flax or wool. Hargreave's 'spinning-jenny' (invented 1764, patented 1770) could not produce a yarn strong and hard enough for warp; but this difficulty was overcome by Arkwright's 'water-frame' (spinning by rollers), brought out in 1769, and further improved in 1775. Hargreave's 'spinning-jenny' was virtually superseded by Crompton's 'mule' (so called from the circumstance that it combined the principles of both Hargreave's and Arkwright's inventions), patented in 1779. It was also called the 'muslin-wheel,' because it produced a finer and more uniform yarn than was possible by either the 'jenny' or the 'water-frame.' Up to the date of Crompton's invention, the progress of the industry had been very slow; the import of cotton in that year being only about 6,000,000 lb., against nearly 4,000,000 lb. in 1764, and nearly 3,000,000 lb. in 1751. In 1785 Arkwright's patents, which comprised improvements connected with carding, drawing, roving, and spinning, were thrown open, and the industry at once advanced by leaps and bounds—the import of cotton reaching 18,000,000 lb. in 1785, and 31,000,000 lb. in 1790, or 45,000 bales of 400 lb., and 77,000 bales respectively. There was now a plethora of yarn, but this was overcome by improvements in weaving. Dr Cartwright invented the power-loom in 1785, and added to its utility in 1787. These were the first improvements since Kay's 'fly-shuttle' (1738) and 'drop-box' (1760). Between 1790 and 1797 the cry was for more cotton; prices advancing from a range of 12d. to 22d. per lb. to one of 25d. to 40d. The spinners looked to India, but the invention of the 'saw-gin' in 1793 brought relief from America, and the import in 1800 reached 46,000,000 lb. In the meantime Bell had invented 'cylinder printing' (1783), which enabled one man and a boy to do the work of 100 men and 100 boys; and in the same year oxymuriatic acid was first applied to bleaching, whereby work which had previously taken up several months could now be done in a few days. Watt's steam-engine was invented in 1769, improved in 1781, and first used in connection with cotton-spinning and manufacturing in 1785. Vast improvements have been made upon the original inventions of Arkwright, Crompton, and Cartwright during the present century; but the improvements in spinning were for many years much more rapid than those in weaving. The 'self-acting mule' was brought out by Messrs Sharp & Roberts in 1825, and further improved in 1830, about which time, too, considerable improvements were made in the 'water-frame;' but in the last-named year there were still only about 80,000 power-looms at work against about three times the number of hand-looms. In 1841, however, Messrs Kenworthy & Bullough brought out a power-loom, which, while reducing the labour of the weaver nearly one-half, produced a greater quantity, as well as an improved quality of cloth. Still further improvements have since been made, all tending towards augmented output and diminished cost of production. Hargreave's first 'jenny' contained only 8 spindles, but the number was increased by degrees until it reached 120. At the opening of the present century the 'mule' contained about 200 spindles; it now contains from 1000 to 1200, while within quite recent times the speed at which the spindles run has been increased from 7000 revolutions per minute to 10,000 revolutions. Fifty years since the speed of the loom varied from 90 to 112

picks (throws of the shuttle) a minute; now it ranges from 180 to 200 picks a minute, and in some instances still more. At the Oldham Exhibition there was shown a light calico loom capable of running as high as 400 picks per minute.

The leading economical results of the inventions of a century ago, and of the subsequent improvements are briefly set forth in the following table, which gives the weight of cotton consumed in Great Britain, the weight of yarn, and the quantity of piece-goods exported in millions of lbs. and yards, and the value of all kinds of cotton products exported in various years, commencing with 1779, the year in which Crompton's 'mule' was brought out, followed by 1785, the year in which Arkwright's patents were thrown open. Figures in millions of lbs., yards, and £'s :

Years.	Cotton Consumed.		Yarn Exported.		Piece-goods Exported.		Value of all kinds Cotton Products exported.
	lb.	Average per lb. d.	lb.	Average per lb. d.	Yards.	Average per yd. d.	
1779	6	18	0.3
1785	11	20	0.8
1790	30	17	1.6
1800	52	18	5	..	77	..	5.8
1820	120	11½	23	20½	351	12½	16.5
1840	460	6	118	14½	790	4½	24.6
1860	1084	6½	197	12	2776	3½	52.0
1880	1373	6½	215	13½	4474	3½	75.5
1887	1487	5½	252	10½	4904	2½	70.9

The complete particulars from 1779 to 1800 are not obtainable. The average price of cotton is for West Indian from 1779 to 1790; but for 1800 and since it is for middling American. The value of goods, &c. exported from 1779 to 1800 is the 'official' value; since then, the real or declared value. The average prices of yarn and goods exported are those of the Board of Trade. The effect of the continued improvements in machinery is shown still more strikingly in the following statement of the cost at various dates of producing yarn of forty hanks to the pound. The first line of figures represent the selling-price of the yarn, the second the cost of the cotton used (18 oz. in weight), and the third the balance left for labour and capital :

	1779.	1784.	1790.	1812.	1830.	1860.	1887.
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
Price	16 0	10 11	7 6	2 6	1 2½	0 11½	0 9½
Cotton	2 0	2 0	3 4	1 6	0 7½	0 6½	0 6½
Labour, &c.	14 0	8 11	4 2	1 0	0 6½	0 4½	0 3

The cost of weaving has also been vastly reduced. A species of calico selling at 6s. per yard towards the close of the last century can now be had for as many pence! The decline in the price of calico since 1815 is greater in proportion than the fall in the price of yarn: 40's yarn, for instance, is only worth about one-third the price current in 1812, but calico is not worth more than one-sixth or one-seventh.

The rapid increase in consumption between 1785 and 1790 was due to the spread of Crompton's and Arkwright's inventions. The great increase in the volume of trade, and the material decline in the prices of yarn and piece-goods, between 1820 and 1840, was owing chiefly to the invention of the 'self-acting mule.' The still more important developments between 1840 and 1860 were due chiefly to the improvements in the power-loom, but in a great measure also to the opening up of the trade with China. The progress made in the export branch of the industry is shown more fully in the following account of the shipments of piece-goods and yarn from Britain to the leading districts of the world at various periods from 1820 onwards, in millions of yards and lbs. :

PIECE-GOODS.	1820.	1840.	1860.	1880.	1887.

Continental Europe was the principal outlet for both goods and yarn in 1820, and is so still in respect of yarn. Next followed America. There was a considerable increase in the exports to both districts between 1820 and 1840, but between 1840 and 1860 the business with the Continent was almost stationary, owing to the large increase in domestic cotton industries of the various countries. The trade with the United States increased considerably down to 1860, but since then the highly protective tariff introduced during the war has reduced the business to an insignificant compass. The low prices brought about by diminished cost of production (1840 to 1860) led to a large increase in the trade with Turkey, and there has since been an almost constant, though more gradual, movement in the same direction. One hundred years ago, about the time when Arkwright's patents were thrown open, Manchester complained loudly of the injurious competition of calico imported from India, and from time to time the duties were increased. About fifty years later (1831) the manufacturers and dealers of Bengal asked for the removal of these duties, on the ground that the native industry was being seriously injured by the import of cotton fabrics from England, although the shipments from this side had not yet assumed important proportions. Even in 1840 they were only 145 million yards, but in 1860 they reached 825 million yards, thanks to the improvements in the power-loom already mentioned. The same circumstance, and the opening of the ports in 1841-42, led to a similar expansion in the trade with China. Since 1869 (except the temporary interruption occasioned by the cotton famine), the business with the East has been largely augmented, and now more than half the piece-goods and more than one-third of the yarn exported from Great Britain go to India and China.

The following statement gives the weight of yarn produced, number of spindles at work, number of hands employed, and the production per spindle and hand in Great Britain, at various dates:

	Yarn Produced.	Spindles at Work.	Hands Employed.	Production per Spindle.	Hand.
	lb.	No.	No.	lb.	lb.
1819-21	106,500,000	7,000,000	110,000	15.2	1068
1829-31	216,500,000	10,000,000	140,000	21.6	1546
1844-46	523,300,000	19,500,000	190,000	26.8	2754
1859-61	910,000,000	30,400,000	248,000	30.0	3671
1886-87	1,415,000,000	43,000,000	245,000	32.9	5900

A portion of the yarn produced is exported; the balance is woven into piece-goods. The particulars compare as follows:

	Goods Produced.	Looms at Work.	Hands Employed.	Production per Loom.	Hand.
	lb.	No.	No.	lb.	lb.
1819-21	80,620,000	225,000	250,000	335	842
1829-31	142,000,000	305,000	275,000	470	621
1844-46	348,110,000	282,000	210,000	1234	1681
1859-61	650,870,000	400,000	203,000	1627	3206
1886-87	1,162,000,000	580,000	255,000	2003	4559

There were 240,000 hand-looms and 15,000 power-looms at work in 1819-21; 225,000 and 20,000 respectively in 1829-31; and 60,000 and 82,000

respectively in 1844-46. In 1859-61 the hand-loom had practically disappeared.

The factory returns for 1885 gave the number of spindles in the United Kingdom as only 44,348,921 against 44,206,690 in 1878, of which 40,121,451 against 39,527,920 were spinning-spindles, but these figures were defective. The number of spinning-spindles actually in existence was certainly little if any less than 43,000,000, as about 3,000,000 had been put up in the Oldham district alone between 1878 and 1885. The number of looms is stated as 560,000, but this is also too small. In 1888 it was said by those in the trade that about 600,000 were at work, and 580,000 is a fair estimate for 1886-87. The capital employed in the industry may be stated as follows:

43,000,000 spinning-spindles and 5,000,000 doubling-spindles. Probable cost 24s. per spindle, present value about 18s. per spindle.	£43,200,000
580,000 looms. Probable cost £24 each, present value about £20 each.	11,600,000
Floating capital requisite to carry on the business	25,000,000
Capital employed in printing, bleaching, and other works.	18,000,000
Capital employed in the manufacture of cotton, lace, and hosiery.	7,000,000
Total.....	£104,800,000

According to the census tables for 1881 there were 686,000 operatives and others employed in the cotton industry. In 1889 there were about 700,000. The average rate of wages is about £42 per annum, or a total of £29,400,000. The amount paid for raw cotton in 1887 was £34,460,000—viz. 1,486,855,000 lb. at 5½d. per lb. The value of all kinds of cotton products exported was £70,957,000, and the value of the products consumed at home £30,440,000. These figures compare as follows with those for 1859-61:

	1859-61.	1887.
Value of products exported.....	£49,029,000	£70,957,000
Value of home consumption.....	27,971,000	30,440,000
Total value of products.....	£77,000,000	£101,397,000
Paid for cotton.....	20,290,000	34,460,000
Paid for wages.....	20,995,000	29,400,000
Balance for all other exp. and profits	20,715,000	37,537,000
Total as above.....	£77,000,000	£101,397,000

Taking into consideration the persons employed in the building of the mills and making of the machines, and in the buying and selling of the raw and manufactured articles, it will be found that something like 4½ to 5 million individuals are dependent upon the prosperity of the cotton trade for their livelihood.

The earnings of the work-people have upon the whole steadily increased from year to year. The following table furnishes the rates current in 1839, 1849, 1859, and 1887. It will be observed that the proportionate advance during the last-mentioned period was on an average much greater in the lowest than in the highest paid hands:

	1839.	1849.	1859.	1887.

Note.—(1) Women and girls; (2) young men; (3) women and young men; (4) girls 14 to 18 years; (5) young women; (6) women and men.

The average rate of wages paid in 1887 was about 80 per cent. more than in 1839, 69 per cent. more than in 1849, and 55 per cent. more than in 1859. In the meantime, the hours of labour have been reduced from 69 per week to 56½ per week.

Continental Europe.—Up to within about fifteen years from the close of the last century, the quantity of cotton consumed on the Continent was certainly larger than the weight spun in England; but at the close of the century, thanks to the mechanical inventions to which reference has already been made, England unquestionably stood first. Severe penalties were inflicted upon any one found guilty of either enticing cotton operatives or of exporting cotton machinery to foreign countries. Nevertheless, both operatives and machinery found their way to various portions of the Continent; and cotton-spinning on the English plan was introduced into Russia in 1799, Switzerland in 1800, Belgium in 1801, and France in 1803. Germany, Holland, Spain, Italy, and Austria followed later on. Between 1801 and 1821 France increased its consumpt from 42,000 bales (of 400 lb.) to 80,000, and the rest of the Continent from 33,000 to 80,000.

The chief increase on the Continent between 1811 and 1821 was gained after the peace of 1815. The consumption in France in 1816 was only about 65,000 bales. France held the lead on the Continent until the war of 1870, since which she has been passed by Russia and Germany. The following table shows the progress made by each country since 1830. It gives the consumption of cotton in the years named in 1000's of bales of the uniform weight of 400 lb. each.

Countries.	1830.	1840.	1850.	1860.	1870.	1880.	1886.

Total.....	344	632	1001	1767	1841	2854	3535

The large increase between 1840 and 1850, especially in Russia, was partly due to the repeal (1843) of the enactment which prohibited the export of cotton machinery from this country. The figures for 1869 are given instead of those for 1870, because the movements of trade in the last-named year were disturbed by the Franco-German war. The small general increase between 1860 and 1869, compared with that in the previous decade, was due to the cotton famine incidental to the American war. In 1871, 1,500,000 spindles (those of Alsace) were transferred from France to Germany. This accounts for the decrease in the quantity of cotton consumed in France in 1880 as compared with 1869, and for part of the exceptionally large increase in quantity consumed in Germany. The total number of spindles in France in 1869 was 6,120,000; in 1870, 4,620,000. As less than 1,600,000 people had been transferred along with the 1,500,000 spindles, the 4,620,000 remaining spindles had to supply yarn for a population of 46,000,000. The consequence was considerable activity in mill-building or enlarging, and by 1872 the number of spindles had increased to 5,011,000. During the subsequent ten years there was very little change, except the substitution of new for old spindles, which enabled the spinners to turn off a greater weight of yarn. In 1884 there were in France 5,111,000 spindles, of which 227,000 were idle, against 5,011,000 and 385,000 respectively in 1872. The number at work in 1884 was 4,884,000 against 4,626,000 in 1872. The cotton industry of Switzerland has been almost

stationary of late years, owing to the adverse influence of foreign competition and hostile tariffs, and there are no more spindles at work than there were ten years ago, while the number in existence is smaller owing to mills burned down not having been rebuilt. The figures for Italy are exclusive of cotton grown in Italy itself, of the extent of which there are no authentic records. The quantity has been quite small, however, during the past fifteen years. Besides the countries mentioned above, there are about 24,000 bales of 400 lb. used in Portugal, and about 18,000 bales spun in Greece.

The following is a statement of the number of spindles and the weight of cotton spun in each country in 1886:

Country.	Number of Spindles.	Cotton Consumed, lb.	Per Spindle.
Russia.....	4,400,000	264,000,000	60.0
Sweden.....	320,000	28,000,000	87.5
Germany.....	5,150,000	356,000,000	69.1
Austria.....	2,085,000	184,000,000	88.2
Switzerland....	1,850,000	52,000,000	28.1
Holland.....	290,000	24,000,000	82.3
Belgium.....	840,000	52,000,000	61.9
France.....	4,900,000	240,000,000	48.9
Spain.....	2,035,000	110,000,000	54.0
Portugal.....	140,000	10,000,000	71.4
Italy.....	1,210,000	104,000,000	85.1
Greece.....	65,000	7,150,000	110.0
Total.....	23,255,000	1,431,150,000	61.1

The Russian figures are exclusive of cotton received from Asia, estimated at 100,000 bales of 400 lb. per annum. The variations in the average weight of cotton per spindle are occasioned by the differences in the counts of yarn spun, or in the number of hours worked per day. Switzerland consumes only a small weight of cotton per spindle because she produces very fine yarns, similar to those spun at Bolton.

America.—The first cotton-mill built in the United States was put up in 1793. Others followed at short intervals, but the progress was not very rapid until during the war of 1812-14, which led to such an extraordinary rise in prices, that cotton goods similar to those which had been imported from England at 20 cents per yard rose to 75 cents per yard. This stimulated mill-building to such an extent, that when the war was over, and importations resumed, prices fell back to a lower point than ever, and the new domestic industry suffered so severely that an agitation was at once commenced in favour of increased import duties. Hitherto the tariff on imported textiles had been only from 7½ to 10 per cent.; but in 1816 the duties were raised all round to 25 per cent., and henceforth the protected industry made rapid progress: the consumption of cotton advancing from 80,000 bales of 400 lb. in 1820, to 340,000 in 1840, and 968,000 bales in 1860. Thence to 1870 there was only a slight increase; the quantity consumed in that year being only 996,000. In 1880 it reached 1,920,000 bales; and in 1887, 2,795,000 bales. The census returns of 1880 gave the amount of capital employed in the cotton manufacturing industry as £41,756,000, including £3,533,000 in the South; the number of spindles as 10,678,516, including 583,696 in the South; the number of looms as 227,156, including 12,194 in the South. In 1887 there were 13,500,000 spindles in the States, including 1,225,000 in the South. The consumption of cotton represented 30 per cent. of the crop against about the same in 1880, but against only 18 per cent. in 1860, and 17 per cent. in 1840. The New England manufacturers have hitherto been unable successfully to compete with the old country in the outside markets of the world; the value of the entire exports of cotton products in 1887 being only £2,986,000, against £1,996,000 in 1880, £757,000 in 1870, £2,187,000 in 1860, £947,000 in 1850, and £710,000 in 1840.

The cotton industry of *Canada* has recently gained in importance. The consumption in 1887 was about 80,000 bales of 400 lb., against about 40,000 bales in 1881, and only about 15,000 bales in 1877. There are about 300,000 spindles at work. The consumption of cotton in *Mexico* in 1887 was about 130,000 bales of 400 lb., and there were about 500,000 spindles at work. The native consumption of *Brazil* and other parts of *South America* is estimated at about 100,000 bales of 400 lb., but it probably exceeds this figure.

Asia.—One hundred years ago Lancashire complained that her then new industry was being injured by the competition of goods imported from *India*; fifty years later Indian manufacturers complained of the injurious influence of imports from England; and now Lancashire is once more in fear of the competition of India; not on account of imports into England (these, so far, being only slight), but on account of the extensive shipments of Indian-spun yarn and Indian-made goods to China, Japan, and other markets in the East. This competition is only of recent growth, and has arisen from the extensive erection of cotton-mills in Bombay and elsewhere, on the Lancashire plan. In 1861 there were only 338,000 spindles at work in all India, and as late as 1874 the number was only

593,000; but there are now 2,420,000 at work. The movements for the past eleven years, as shown in the figures for 1877, 1882, and 1887, compare as follows:

	1877.	1882.	1887.
Cotton spun, lb.	88,800,000	154,400,000	284,890,000
Yarn exported, lb.	8,796,000	33,230,000	91,804,000
Goods exported, yards.	15,544,000	23,900,000	53,405,000
Weight of exports, lb.	11,905,000	39,211,000	102,485,000

In arriving at the total weight of yarn and goods exported, it is assumed that 5 yards of goods are equal to 1 lb. of yarn.

The cotton crop of *China*, as already stated, is about 1,500,000 bales of 400 lb. The whole is consumed at home, along with about 100,000 bales imported from India. *Japan* produces about 100,000 bales, of which only trifling quantities are exported. Japan is imitating Bombay, and there are now about 200,000 spindles at work. Of these, 120,000 were put up in 1888.

Recapitulation.—The following statement shows the relative importance of the cotton industries of Great Britain, continental Europe, the United States, and India, as exhibited in the quantity of cotton consumed in each of the various seasons named since that of 1860-61, in 1000's of bales of 400 lb.:

	1860-61.		1862-63.		1870-71.		1878-77.		1882-83.		1886-87.		1887-88.

Continent.	1723	31.8	732	31.0	1962	31.7	2460	33.0	3437	34.4	3640	34.7	3770	34.6
United States.	1009	18.7	435	18.4	1116	18.1	1571	21.1	2360	23.6	2448	23.3	2523	23.2
India.	65	1.2	32	1.4	87	1.4	231	3.1	431	4.3	710	6.8	771	7.0
Total.	5411	100.0	2360	100.0	6178	100.0	7434	100.0	9998	100.0	10,489	100.0	10,910	100.0

The figures for 1862-63 are inserted as showing the effect of the American war. As respects the general movement, Great Britain held her own between 1860-61 and 1870-71; but since then her competitors have made relatively and positively much greater progress, but so far without encroaching upon our export trade. The diminished consumption in Great Britain in 1886-87 as compared with 1882-83 was due partly to 'short-time' in the summer, and partly to the circumstance that the American crop was less wasty than that of 1882-83. The increased production on the Continent is almost entirely consumed at home, and is due partly to the improved economical condition of the people, and partly to the circumstance that cotton goods are overtaking linens and woollens. The increased production in the United States is also mostly consumed at home. Lancashire's only formidable competitor in the outside markets of the world is India, but even in this respect nothing serious has yet taken place. The increase in the Indian mills has, so far, been chiefly at the expense of the old native hand industry, which is rapidly disappearing.

A recapitulation of spindles compares as follows:

	1861.	1877.	1887.
Great Britain.	30,300,000	39,500,000	43,000,000
Continent.	10,000,000	19,600,000	23,750,000
United States.	5,000,000	10,000,000	13,500,000
India.	338,000	1,230,000	2,400,000
Total.	45,638,000	70,330,000	82,650,000

Cotton-seed Oil.—Pulp is now made from cotton stalks, and converted into the finest writing-paper, an enormous saving of waste being thus effected. Cotton seed is remarkably rich in oil, now used for a variety of purposes. The crop of cotton seed in the United States amounts to about 3,500,000 tons. The bulk of this is returned to the ground. In 1887 about 500,000 tons were crushed at the

oil-mills of the United States—producing 175,000 tons of cake, 75,000 tons of oil, and 6250 tons of linters (the short fibres left on the seed after ginning); the remaining 243,750 tons being waste. The total cotton-oil product is estimated at from 15,000,000 to 17,000,000 gallons, most of which is consumed in the manufacture of lard, which it is said to equal for culinary purposes. Cotton-seed cake or meal is especially rich in nutritious matter for farm-stock, causing cattle to fatten rapidly, and producing very rich milk (though the butter is not improved). Boiled cotton seed with hay or straw is admirable feeding. The seed is worth in America about £4, 10s. per ton; the oil, 1s. 3d. per gallon; the cake, £3, 10s. per ton; and the linters, 2½d. per lb. About 300,000 tons of Egyptian cotton seed are crushed in Great Britain per annum.

The Cotton Famine.—The American civil war broke out in 1861, and in 1862 our import of cotton fell to 524 million lb., against 1257 million in 1861, and 1391 million in 1860. Increased supplies from India and other sources brought the arrivals up to 669 million in 1863, 893 million in 1864, and 978 million in 1865. The war closed in 1865, trade with America was resumed, and the imports in 1866 rose to 1377 million lb., and the cotton industry shortly afterwards resumed its former dimensions. At the crisis of the famine the mills were not working more than half-time, and in December 1862, 247,000 cotton operatives and others connected with the trade were out of employment, and 165,000 others only partially employed. In the same month, 234,000 persons, or 24 per cent. of the total population of the districts affected, were in receipt of charitable relief. In 1863 the average number of persons out of work was 189,000, and that of those only partially employed, 129,000; in 1864 the figures were 134,000

and 97,000 respectively; and those for the first five months of 1865, 107,000 and 68,000. During the course of the famine the losses of the trade amounted to between £65,000,000 and £70,000,000, including from £28,000,000 to £30,000,000 loss of wages to operatives. Of the latter amount about

one-fourth was recovered in the form of relief, or in wages for employment in public works, &c. The total sum distributed in charity alone was fully £23,000,000, and may have reached £4,000,000. The *extra* expenditure of the guardians reached £1,287,994, and the sum of £1,560,466 was dis-

tributed by relief committees, making a total of £2,848,460; but there was a vast amount of relief given, in money or kind, of which there is no record. In some districts in 1863 the poor-rate rose to nearly 6s. in the £. In the same year, the average rate for the whole of the cotton districts was 2s. 2½d., against only 7½d. in 1861.

For the manufacture of cotton, see SPINNING, WEAVING, CALICO-PRINTING, &c. And see for further information Ellison, *The Cotton Trade of Great Britain* (new ed. 1886); Marsden, *Cotton Manufacture* (new ed. 1886); Dr Forbes Royle, *Culture and Commerce of Cotton in India* (1851); and Dana, *Cotton from Seed to Loom* (New York and London, 1878).

Cotton, CHARLES, the friend of Izaak Walton and translator of Montaigne, was born at his father's estate of Beresford in Staffordshire, 28th April 1630. His father, himself a man of great ability, was a warm friend of Ben Jonson, Selden, Donne, and other illustrious men. The boy travelled on the Continent, devoted himself from youth to a life of letters, and early wrote verses which were handed about among his friends. In 1656 he married his cousin Isabella, sister of the famous Colonel Hutchinson. Though a sincere loyalist, he seems to have lived securely enough under the Commonwealth, and the decay of his father's estate was due mainly to unprosperous lawsuits. In 1664 Cotton issued anonymously his burlesque poem, *Scarronides, or the First Book of Virgil Travestie*,

added to in later editions in grossness as well as in bulk. Later books, somewhat of the same character, are his *Voyage to Ireland in Burlesque* (1670), and his *Burlesque upon Burlesque, or the Scoffer Scoff, being some of Lucian's Dialogues* (1675). His *Planter's Manual* (1675) testifies to his zeal and taste for horticulture. Next year he contributed a treatise on fly-fishing to the fifth edition of Walton's *Complete Angler*, and here he commends his old friend and master, its author, as 'the best and the truest friend ever man had.' Further marks of affection were his commendatory verses in the 1675 edition of Walton's *Lives*; his poem, *The Contentation*, as well as an earlier one of invitation to Walton to visit him; and the twisted cipher of his own and his master's names above the door of his fishing-house on the Dove. In 1685 Cotton published his translation of Montaigne's *Essays*—a masterpiece on which his fame still rests securely. He died in 1687. Cotton's verses are full of rare felicities of thought and phrase, and are more really poetical than much far more pretentious poetry. His prose is simple and clear, direct and vigorous. His character was eminently lovable; his only troubles, his debts; his only enemies, his duns.

Cotton, GEORGE EDWARD LYNCH, D.D., bishop, born in 1813, was educated at Westminster and Cambridge, and from 1836 to 1852 was master at Rugby under Arnold and Tait; in 1852

Brown's School Days he appears as 'the young master.' For six years he was at the head of Marlborough College, which he raised to a position among the first schools of England. In 1858 he was consecrated Bishop of Calcutta, where he successfully administered his immense diocese, and where his schools for the children of the poorer Anglo-Indians and Eurasians are monuments of the services he rendered to education. He was drowned in the Ganges, 6th October 1866.

Cotton, JOHN, clergyman, born at Derby in 1585, was a tutor at Cambridge, and from about 1612 held a charge at Boston, in Lincolnshire. Cited to appear, for his Puritan views, before Laud at the high commission court, he in 1633 fled to Boston, in New England, where he preached until his death in 1652. Cotton was reputed a profound scholar, and was the author of nearly fifty works, including a catechism, forms of prayer, and a defence of the interference of the civil authority in religious matters, in a famous controversy with Roger Williams.

Cotton, SIR ROBERT BRUCE, an English antiquary, was born at Denton, Huntingdonshire, 22d January 1571. From Westminster School, where he had the famous Camden for master, he passed to Jesus College, Cambridge, where he graduated B.A. in 1585. He soon settled in a house in Westminster on the site of the present House of Lords, and here he commenced to accumulate books, manuscripts, coins, and other articles, and to practise that large hospitality that made Cotton House the meeting-place of all the scholars of the kingdom. His papers read before the Antiquarian Society spread wide the reputation of his learning; King James knighted him in 1603, created him a baronet in 1611, and frequently consulted him on political matters. But he kept the scholar in prison for eight months in connection with the Overbury case. He had been returned to parliament in 1604, and soon identified himself completely with the policy of constitutional opposition to the crown. His protest against the proposed debasement of the coinage (1626), his frank criticism of kingcraft in his *History of Henry III.* (1626-27), his outspoken review of the present political situation in his tract, *The Dangers wherein the Kingdom now Standeth, and the Remedy* (1628), and the frequent meeting in his house for deliberations of Eliot, Pym, Selden, and Sir E. Coke, marked him out to the court as an enemy to be crushed. The occasion was soon found. An ironical tract, entitled *A Proposition for His Majesty's Service to Bridle the Impertinency of Parliaments*, having fallen into the hands of Wentworth, it was found on inquiry that the original was in Cotton's library, from which a copy had been made, though without his knowledge, for the press. Cotton and others were flung into prison, but proceedings were stayed and the prisoners released on the occasion of the birth of an heir to the throne (29th May 1630). But Cotton's library was not restored to him in spite of his pathetic petitions, and as his heart was bound up in his books, he pined and died less than a year after (6th May 1631). Fourteen of his tracts were collected and published as *Cotton's Posthuma* in 1657. His son, Sir Thomas Cotton (1594-1662), had the books restored to him; and his great-grandson, Sir John Cotton (1679-1731), bestowed the library on the nation.

THE COTTONIAN LIBRARY was accordingly removed to Ashburnham House, Westminster, in 1730. In the following year a fire occurred in the house, in which about 114 out of the 958 volumes of MSS. which the library contained were reported as 'lost, burned, or entirely spoiled; and 98 damaged so as to be defective.' The library was

transferred to the British Museum (see Vol. II. p. 462) in 1753.

Cotton-grass (*Eriophorum*), a genus of Cyperaceae, in which the perigone or covering of united bracts, which in this order inclose the ripening ovary, is developed into long silky or cottony hairs, which used to be employed for candle-wicks, stuffing pillows, &c. A more recent attempt to employ these as a substitute for cotton has naturally failed, nor is the herbage willingly eaten by sheep or cattle. Two species are common in Britain, and give a characteristic appearance to bogs and wet moors.

Cotton-wood. See POPLAR, SILK-COTTON.

Cotton-worm is a common name for the caterpillar of an owlet moth (*Aletia xylinia*), which is in some years very destructive to the cotton crop of the United States. The caterpillar is green, with yellow stripes and black dots, and grows to a length of an inch and a half. The boll-worm, the caterpillar of an allied form (*Heliothis armigera*), is also very destructive to cotton-buds and other crops.

Cottus, a genus of acanthopterygious fishes, comprising the Bullhead (*C. gobio*) of British rivers, the marine Father Lasher (*C. scorpius*), and the closely akin *C. dubalis*, found on the coasts of California and Georgia. See BULLHEAD.

Cotyledon (Gr., 'a cup or cup-shaped hollow') is the technical term applied by botanists to the seed-leaves of the embryo. Their morphological importance was formerly somewhat exaggerated, as they were supposed to be quite unrepresented even in the higher cryptogams (see FERNS, &c.), to which the term *acotyledonous*, now disused, was therefore applied. The number of cotyledons is, however, usually of high systematic importance; for although in Gymnosperms it varies from a whorl of eight, ten, or even more in conifers, to usually two in cycads, it is almost constant among the higher Angiosperms, the old division of monocotyledons and dicotyledons having few exceptions to its literal accuracy. Every one is familiar with the two cotyledons of so many seedlings of the latter group; but a more extended study shows that many never emerge above ground, or even leave the seed. The form and structure of the cotyledons depends largely on whether they have precociously absorbed and stored the nutritive contents of the endosperm; in this case, of which the leguminous seeds of pea, bean, &c. afford the most familiar example, they become more or less fleshy, and frequently do not appear above ground in germination. The mode of packing the cotyledons in the bud also presents many differences in detail of high systematic constancy, and therefore importance. See OVULE, SEED, EMBRYO, and GERMINATION.

Coucal (*Centropus*), or LARK-HEELLED CUCKOO, a genus of common bush-birds in Africa, India, and through the Malayan Archipelago to Australia. The hind-toe is prolonged into a very long spur.

Common Cotton-grass (*Eriophorum angustifolium*).

Their call is loud and in some cases apparently ventriloquistic. They build their own nests. See CUCKOO.

Couchant. In Heraldry, a beast lying down, with his head up, is couchant. If the head is down, he is dormant.

Couch-grass (*Triticum repens*), also called *Wheat-grass*, *Dog-grass*, *Quickens*, and *Squitch* or *Quitch*, a grass which, although of the same genus with wheat, is a widespread and troublesome weed. Its perennial creeping root-stocks render it extremely difficult of extirpation; they are carefully gathered out of land under cultivation; but in times of scarcity have been employed as human food, as a source of beer, as a domestic medicine, and more frequently as fodder. They are sometimes useful in binding sand into pasturage of inferior quality. Cut early, couch-grass makes very good hay.

Couching. See CATARACT.

Coucy, **RAOUL** or **RENAULT**, **CASTELLAN** DE, was a French court poet or Trouvère (q.v.) of the 12th century, to whom twenty-three poems are ascribed. He was named after the Château de Coucy, near Laon. See Gaston Paris in *Romania* (1872).

Coughing, considered physiologically, consists (1) in a long inspiration which fills the lungs to a greater extent than usual; (2) in the closure of the glottis, or narrow opening in the organ of voice (see LARYNX), at the commencement of the act of expiration; and (3) in the sudden forcing open of the glottis by the violence of the expiratory movement. In this way, a blast of air is driven upwards from the lungs through the mouth, which carries with it any sources of irritation that may have been present in the air-passages. Coughing may occur from irritation in the back of the throat, in the larynx, trachea, or bronchial tubes, and may be excited by acrid vapours, by irritant gases, or by articles of food or drink—such as even a drop of water or a crumb of bread—making their way into the air-passages instead of into the pharynx, or by excessive or morbid secretion from the walls of the air-tubes, or even by the entrance of cold air, when the lining membrane of the air-passages is abnormally irritable. More rarely it results from irritation of other parts, as the ear, and possibly the stomach.

The object of coughing in the animal economy is unquestionably to guard against the danger of the entrance of mechanical and chemical irritants into the air-passages; and accordingly the mucous membrane, especially of their upper part, is endowed with a most exquisite sensibility which, when aroused by irritation or by a state of disease, provokes incessant coughing until the irritation be allayed or removed. Cough is an exceedingly common symptom of all diseases of the respiratory organs. The treatment of coughing must first be directed to the removal, if possible, of the cause which excites it. But besides, when once begun, coughing frequently becomes excessive, and so irritating or exhausting to the patient, from too great sensitiveness of the nervous mechanism which produces it; and this tendency, when injurious, must also be combated. The remedies suitable to most cases of cough are therefore Expectorants (q.v.) and nerve sedatives, especially opium, morphia, and hydrocyanic acid; 'cough mixtures' generally contain both. Such household remedies as liquorice, jujubes, black-currant jelly, or linseed tea are often of service. See also under names of diseases in which cough occurs.

Cough occurs amongst the lower animals under similar conditions. From continued breathing of a close foul atmosphere, the bronchial mucous

membrane becomes unduly irritable, hence the prevalence of chronic cough amongst the cows in our overcrowded town-dairies. Chronic cough also occurs in horses, usually as a sequel to an attack of cold. It constitutes unsoundness, is best treated by repeated doses of belladonna and camphor, but often requires for its entire removal a run at grass.

Cough is an accompaniment of teething, and is also common in diseases of the digestive organs. See PNEUMONIA, CONSUMPTION, BRONCHITIS, CATARRH, &c.

Couguar. See PUMA.

Coulmiers, a French village, some 12 miles WNW. of Orleans, where Von der Tann and his Bavarians were defeated by an overwhelming force under D'Aurelle de Paladines, 9th November 1870.

Coulomb, **CHARLES AUGUSTIN** DE, famous for his experiments on friction, and the invention of the *Torsion Balance* for measuring the force of magnetic and electrical attraction, was born at Angoulême in 1736. In early life he entered the engineers, and served some time at Martinique. In 1777 he gained an Academy prize by a work on magnetic needles, and again two years later by his *Théorie des Machines simples*. For speaking the truth about a projected canal in Brittany, he was for some time imprisoned, but earned the hearty approval of the honest Bretons, as well as his own conscience. Coulomb lived in retirement during the Revolution, became a member of the Institute in 1804, and died August 23, 1806.

Coulter. See PLOUGH.

Coumarin ($C_9H_6O_2$) is a fragrant crystalline substance, analogous to volatile oils and camphor, which is present in the well-known Tonka bean. It is identical with the odorous principle of many other plants, including the Woodruff, Melilot, and Vernal grass.

Council, or **SYNOD**, an assembly of ecclesiastics met to regulate doctrine or discipline. We first hear of such assemblies during the Montanist controversy, about 150 A.D. (Ecumenical councils are convoked from all parts of Christendom, and claim to regulate the affairs of the whole church. Other synods have represented the East and West respectively. Patriarchal, national, and primate councils represent a whole patriarchate, a nation, or the several provinces subject to a primate, while the bishops and other dignitaries of a province constitute a provincial; the clergy of a diocese under the presidency of the bishop, a diocesan council. Mixed councils during the middle ages dealt with civil as well as ecclesiastical affairs, and were composed of secular persons as well as churchmen. Sometimes, but not always, the lay and ecclesiastical members voted in separate chambers.

The first eight general councils were convoked by the emperor, all the later ones by the popes, and the fifth Lateran Council asserts (*Sess. xi.*) the modern principle that the right of convoking, removing, and dissolving general councils belongs to the pope. The right of voting was reserved in early times to bishops and priests, or deacons who acted as representatives of absent bishops. From the 7th century onwards this right was sometimes extended to abbots, and from the end of the medieval period to cardinals who were not also bishops. At the Vatican Council the members entitled to vote were cardinals, bishops (even if only titular bishops), mitred abbots, and generals of religious orders. Priests acting as proxies of bishops were not admitted. The presidency at the early ecumenical councils followed no fixed rule. In a certain sense it belonged to the emperor, who

had convoked the bishops, and was responsible for peace and order. 'It was not,' says Harnack (*Dogmengeschichte*, ii. p. 101), 'till the fourth general council that the papal legates gained a unique position, and learned Catholics have admitted that the presidency of the papal legates at Nicæa does not admit of positive proof.' This is true even of Catholic theologians writing after the Vatican decrees. Thus Kraus (*Kirchengeschichte*, p. 147) contents himself with maintaining 'the probability' that the papal legates presided at Nicæa, and Hefele (*Concil.* i. p. 38, 2d ed.) admits that the question is 'not without difficulty.' The modern theory that a council is then, and then only, to be counted general when its acts have been ratified by the pope, is of still later origin. Even medieval theologians, such as Thomas of Walden, maintained that the decisions of general councils did not acquire binding force till they had been accepted by the whole church. And although it was an established principle in the 6th and the following centuries that the definitions of councils, indisputably oecumenical, could not be called in question, it is certain that St Augustine had been of another mind. He asserts (*De Bapt. contra Donat.* ii. p. 3-4) that Scripture alone has final and irrefragable authority, but that even 'plenary councils, assembled from the whole Christian world,' may be 'corrected' (*emendari*) by the accession of knowledge and experience. Moreover, the fact that the decisions even of provincial councils are sometimes attributed, in the 4th century, to the 'suggestion' of the Holy Spirit, shows that caution is needed in interpreting the rhetorical language of early writers.

The Greek Church recognises seven general councils—viz.: (1) The first of Nicæa, 325 A.D.; (2) the first of Constantinople, 381; (3) Ephesus, 431; (4) Chalcedon, 451; (5) second of Constantinople, 553; (6) third of Constantinople, 680; (7) second of Nicæa, 787. To these Roman Catholics add: (8) fourth of Constantinople, 869; (9) first Lateran, 1123; (10) second Lateran, 1139; (11) third Lateran, 1179; (12) fourth Lateran, 1215; (13) first of Lyons, 1245; (14) second of Lyons, 1274; (15) Vienne, 1311; (16) Constance, 1414-18, of which Ultramontanes accept only the decrees passed in sessions 1442-45 inclusive, and such decrees of earlier sessions as were approved by Martin V.; (17) Basel, 1431 and the following years, oecumenical according to Ultramontanes only till the end of the twenty-fifth session, and even then only in respect of such decrees as were approved by Eugenius IV.; (18) Ferrara-Florence, 1438-42, really a continuation of Basel; (19) fifth Lateran, 1512-17; (20) Trent, 1545-63; (21) Vatican, December 8, 1869, to July 18, 1870, and still unfinished.

The best collections of councils are by Hardouin (12 vols. folio, Paris, 1715), and that of Mansi (31 vols. folio, Florence, 1759), which is by far more complete than Hardouin's, but inferior to it in correctness of typography. An excellent account of the councils, with the text of the most important decrees, will be found in Bishop Hefele's *Conciliengeschichte* (7 vols. Freiburg), part of which has been published by Clark in an English translation. For the history of the more important councils, see under NICÆA, BASEL, &c.

Council Bluffs, a city of Iowa, capital of Pottawattamie county, 141 miles WSW. of Des Moines by rail, on a plain backed by the high bluffs from which it takes its name. The Missouri River, 3 miles to the west, is crossed by a grand railway bridge to Omaha, and five railways form a junction at the town, which has manufactures of paper, iron, carriages, and agricultural machines. Pop. (1870) 10,020; (1885) 21,557.

Council of War is a conference of military or naval officers, to consider a plan of campaign, determine the order of battle, or give their opinions on some matter in which the commander wishes to fortify his judgment by an appeal to that of others. The senior officers and heads of departments meet him in the consultation whenever he thinks it desirable; and their opinions are placed upon record. Thus the commandant of a fortress generally solicits the opinion of a council of war before surrendering to besiegers. The British military code leaves its assembly to his discretion, but the French make a special provision for a council of defence. In the navy, a council of war consists usually of flag-officers only; but officers of lower rank occasionally assist.

Counsel. See ADVOCATE and BARRISTER.

Counsellor is the term which in the United States most nearly corresponds to Barrister (q.v.) in England, and Advocate (q.v.) in Scotland. But in the United States there is no such well-marked distinction between counsellor and solicitor as in the United Kingdom obtains between barrister or advocate and solicitor. See LAWYER.

Count (Lat. *comes*, in Fr. *comte*, Span. *conde*, Ital. *conte*), the name of a dignity in medieval and modern Europe, to which Earl (q.v.) is in one view supposed to be analogous, the Latin equivalent of each being the same, and the wife of an earl being a countess. On the various significations of the *comes* of classical times it is unnecessary to enter. Under Constantine the term became an honorary title; and the *comites* became a sort of council of state both in the eastern and western empire, each having his separate office in the household. The counts under the first two races of Frankish kings were (like those of the lower empire) of various degrees. The count of the palace (*comes palatii nostri*) was the highest dignitary in the state after the *maire* of the palace; and in the 11th century he had already acquired a rank apart from that of the other counts. He presided in the court of the sovereign in his absence, and possessed sovereign jurisdiction. The habit of instituting counts-palatine (*comites palatii*) was adopted by Spain and England. Those counts, again, who, at a later period, as rulers of provinces, had attained to something approaching to sovereign power, exercised also the right of appointing counts-palatine under them—e.g. the Counts of Chartres, of Champagne, of Blois, Toulouse, &c.; and the ancient houses of Chartres and of Blois continued to claim in perpetuity the title of count-palatine as that of their eldest sons. Counts of this sovereign class owed their origin to the feebleness of the later Carolingian kings, under whom they contrived gradually to convert the provinces and towns which they had governed as royal officers into principalities hereditary in their families. It was then that the counts came to be known by the names of their counties. Down to the middle of the 14th century they wielded a most formidable power; somewhat broken by the eventually successful struggle of the towns of Northern France to throw off their yoke. In later times there were numerous mere titular counts, and even before the first revolution many titles of count, believed to be pure assumptions, were recognised by the courtesy of society.

The German word *graf*, akin (like *reeve*, *grieve*, and *sheriff*) to the Anglo-Saxon *geréfa*, 'governor,' in time came to be identified with the *comes* or count, the *pfalzgraf* being the German equivalent of the *comes palatii*. In Germany there have been in modern times two classes of counts, one belonging to the *Dynastien-adel*, or higher nobility—i.e. those families whose head had a seat in the diet or estates of the realm; the other

forming the highest class of the lower nobility. Of the former class the larger number, as the price of their acquiescence in the abolition of the old German empire, received the title of prince, and very few now exist. The merely titular counts belonging to the lower nobility are very numerous.

Counterfelt. See COINING.

Counterforts, the buttresses or arches behind the revetments or retaining walls of the ditches of permanent fortifications. They help to support the earth above them and make it more difficult to form a Breach (q.v.).

Counter-guard is a low outwork designed to cover the revetment of a bastion or ravelin from the fire of the enemy's breaching batteries. It is separated from them by a narrow ditch, and lest the enemy should establish a battery on it when captured, the terre-plein, or flat space behind its parapet, is made very narrow. See FORTIFICATION.

Counter-irritants, agents applied to the skin so as to redden (rube-facients), to vesicate (vesicatories or blisters, q.v.), or to produce pustules, purulent issues, or even sloughs of skin and of the subcutaneous textures. The milder counter-irritants are mustard (see CATAPLASM), turpentine applied on warm cloths, and spirit or acetic acid in lotion. The stronger are blisters of Cantharides (q.v.) or of ammonia; Croton-oil (q.v.) or Tartar Emetic (q.v.), in ointment; setons, caustic or pea-issues, and the moxa; and above all, the actual Canthary (q.v.) or hot iron. None of the stronger counter-irritants should be used without careful consideration and medical advice; great mischief is often done by their careless or improper use. Counter-irritants relieve internal pain, check inflammations, and tend to promote the absorption of morbid effusions. Their effect is probably due mainly to reflex action, produced by the impression they cause upon the nerves of the skin to which they are applied.

Amongst horses, counter-irritants are much used for strains and diseases of the joints, but should never be applied, as they too often are, in recent cases, or whilst the part is hot or inflamed. Cantharidine preparations, or ointment of biniodide of mercury, are the most convenient. For cows, use fomentations, followed by the smart friction of mustard-paste; for dogs, soap-liniment, strengthened, if required, by ammonia or turpentine.

Countermarching. See MARCHING.

Countermine. See MINE.

Counterpoint, in Music, has been defined as

'the art of combining melodies.' The name arose from the early system of notation by points. When another part or melody was added to one already represented by a row of points, this was called *punctum contrapunctum*. A single melody is usually taken as the 'subject,' and the part or parts added are called the 'counterpoint.' When this is done according to the numerous and stringent rules of the old authorities, it is called strict counterpoint; but in modern music these rules are much relaxed. The devices of counterpoint are, however, still largely relied on; Wagner, the greatest innovator of our time, being also one of the greatest practical contrapuntists. The aim of Beethoven in his later works to make every part *sing*, and not be a mere filling up of the harmony, may be referred to as illustrating the object of these devices; and there is no doubt that as used by the classical writers, they are the source of some of the grandest effects in music.

In simple counterpoint the parts are written above or below the subject without regard to their capability of being transposed. It is divided into different species, according as the added parts contain one, two, or four notes against each note of the subject, or are written in syncopated notes, or have a combination of all or any of these, when it is called 'florid.' The so-called 'rules' are in effect limitations of the degrees in which the parts may progress—e.g. the prohibition of consecutive octaves and fifths. The general principle of them is to secure complete *independence* of melodic motion in the parts, while at the same time the laws of harmony are observed. When the parts reach the number of eight or more in vocal music, they are sometimes divided into different choirs, which sing alternately together and in antiphony. A famous example of this class is Tallis's motet 'Spem in alium non habui,' for forty voices, in eight choirs, each of five voices. In double counterpoint the subject and counterpoint are so written that each may form the bass to the other. When in this transposition the upper part is taken to the octave below, or *vice versa*, it is called double counterpoint at the octave; but it may also be at any other interval, the fourth, fifth, &c., or even at two different ones. In treble counterpoint each of three melodies can be put as the bass to the others; and similarly in quadruple and quintuple counterpoint; but counterpoint beyond double can only be at the octave, as the other intervals are impracticable. One or more free parts may be added to fill in the harmony. The following instance of quintuple counterpoint is taken from the finale of Mozart's 'Jupiter' Symphony:

Among the other devices of counterpoint may be mentioned those of contrary motion, augmentation, and diminution, the latter two referring to the time-values of the notes. See IMITATION.

The history of the art of counterpoint can be traced step by step from its beginnings in the rude efforts at part-writing, called *organum*, barbarous to modern ears, in medieval church music, of which

the earliest known account we have is by Hucbald, a Flemish monk, who died in 930. The earliest existing specimen of part-music is an English one—a *rota* or round, written by a monk of Reading in 1226 to words beginning 'Sumer is icumen in,' the MS. of which is in the British Museum. The Polyphonic schools of composition in Flanders, England, Germany, and Italy, of the four succeeding centuries, reaching their culmination in Palestrina, were based pre-eminently on counterpoint. Bach is, however, usually considered its greatest master. There is an enormous number of treatises on the subject in most European languages; it will be sufficient to refer to that of Sir F. A. G. Ouseley, based on Cherubini, and to the primers published by Novello & Co.

Counterscarp is that side of the ditch of a fort which is nearest to the besiegers; the other side being called the *escarp* or *scarp*.

Countersign, in military affairs, is a watch-word used to prevent unauthorised persons passing a line of sentries whose orders are to stop any one unable to give it. It is fixed each day by the commanding officer, but may be changed at any moment if necessary, and is only communicated to those entitled to know it.

Counter-tenor, the highest adult male voice, the same as Alto (q.v.). See also CONTRALTO, TENOR.

Country-dance (Fr. *contre-danse*, of which the English term is a corruption), a dance in which as many couples can take part as there is space to accommodate them; the gentlemen being ranged at the commencement on one side, and the ladies on the other. The dancers are constantly changing places, leading one another back and forward, up and down, parting and uniting again. 'Sir Roger de Coverley' is the best known example. See DANCING.

County (derived from Fr. *comté*; Lat. *comitatus*) is now the recognised subdivision of the three kingdoms for judicial and local government purposes.

History.—The term 'county' corresponds with shire (Saxon, *scir*, from *sciran*, 'to divide'), a word which, however, it has now to a great extent superseded. It means a division of a kingdom immediately superior to the hundred, and its first use was in connection with the assignment of jurisdiction for judicial business. Some counties, such as Essex, Kent, Middlesex, Surrey, Sussex, were ancient Saxon kingdoms, but other counties or shires were formed by the subdivision of Mercia, Wessex, Northumbria, and the other Saxon kingdoms. The shire represented in its constitutional machinery either the national organisation of the several divisions created by West Saxon conquest, or that of the early settlements which united in the Mercian kingdom as it advanced westwards, or the rearrangement by the West Saxon dynasty of the whole of England on the principles already at work in its own shires. The division of England into shires, which was begun before the time of Alfred, was probably not completed till the Danes, Angles, and Saxons were united into one kingdom under Edgar. In the government of the shire there were two officers, the ealdorman and the *scir-geréfa*, or sheriff. The ealdorman (the *princeps* of Tacitus, the *satrapa* of Bede, the *dux* of the Latin chroniclers, and the *comes* of the Normans) was originally elected by the Witan, but in course of time the office tended to become hereditary, though in all cases down to the Norman Conquest the consent of the king and the Witan was necessary to each fresh nomination. The ealdorman shared with the sheriff and the bishop the administrative functions of the county in the shire-moot. The sheriff was

the representative of the king alone, and was the chief judicial officer of the shire, on whom was imposed the duty of executing the law and acting as steward of the royal demesne. Each county or shire comprised a number of hundreds, and just in the same way as the hundreds had their moot, so each county or shire had its moot, which was attended by the representatives of the hundreds and townships, and by a representative body of witnesses to give validity to its proceedings. According to the laws of Edgar, the shire-moot was held twice a year. After the Conquest the shire-moot continued to be held in each county, but its independence was much interfered with by the exercise of the royal prerogative. Between the reigns of Henry I. and Henry III. these courts began to meet more frequently, and eventually as county courts, or sheriff's courts, met once a month, and continued to be held, though under varying conditions, until comparatively modern times.

Constitution.—The organisation of a county in England comprises the following officers: (1) A lord-lieutenant, who is the military representative of the crown, and whose duty it is to select persons for the commission of the peace; (2) a *custos rotulorum* (keeper of the records); (3) a sheriff; (4) a coroner; (5) justices of the peace, qualified by an estate in possession of £100 a year, or in reversion of £300 a year, or by two years' assessment to the inhabited house duty at £100. All the justices for a county hold the general and quarter sessions as prescribed by law. A single justice may act in petty sessions. (6) A clerk of the peace, who is appointed by the *custos rotulorum*, but may be removed by the justices; (7) a county treasurer; (8) a surveyor, and other minor officers. The duties that now belong to the county justices are mainly of an imperial character, and relate to the maintenance of the militia, to the local administration of the criminal law, and to the carrying out of certain matters connected with parliamentary representation, licensing, assessment, appeals, and so forth.

County Councils.—By the Local Government Act, 1888, all duties purely relating to matters of local government in England and Wales that were performed by the justices in quarter sessions were transferred to county councils which were newly established by the act. These councils are elected by the inhabitants of the county, who are enrolled as 'county electors' for the purpose. A county elector may be a man or woman, but must be of full age and not subject to any legal incapacity, and must not have been in receipt of parochial relief. Such a person must have been an occupier of some building or land in the county for a certain term, and must have paid all rates due and complied with certain conditions as to residence, &c. For the purposes of the establishment of county councils in England and Wales what are termed administrative counties are formed. Of these there are sixty, and the number of county councillors and county aldermen for each county council is as follows, the aldermen forming one-fourth of the total in each case, viz.: *England*—Bedford, 68; Berks, 68; Bucks, 68; Cambridge (exclusive of the Isle of Ely), 64; Cambridge (Isle of Ely Division), 56; Chester, 76; Cornwall, 88; Cumberland, 80; Derby, 80; Devon, 104; Dorset, 76; Durham, 96; Essex, 84; Gloucester, 80; Hereford, 68; Herts, 72; Hunts, 52; Kent, 96; Lancaster, 140; Leicestershire, 72; Lincoln (Holland), 56; Lincoln (Kesteven), 64; Lincoln (Lindsey), 76; London, 137; Middlesex, 72; Monmouth, 64; Norfolk, 76; Northampton (exclusive of the Soke of Peterborough), 68; Northampton (Soke of Peterborough), 40; Northumberland, 80; Notts, 68; Oxford, 76; Rutland, 28; Salop, 68; Somerset,

88; Southampton, 100; Stafford, 100; Suffolk (Eastern Division), 76; Suffolk (Western Division), 64; Surrey, 76; Sussex (Eastern Division), 68; Sussex (Western Division), 60; Warwick, 72; Westmoreland, 56; Wilts, 80; Worcester, 76; York (East Riding), 68; York (North Riding), 80; York (West Riding), 120. *Wales*—Anglesey, 56; Brecknock, 60; Cardigan, 64; Carmarthen, 68; Carnarvon, 64; Denbigh, 64; Flint, 56; Glamorgan, 88; Merioneth, 56; Montgomery, 56; Pembroke, 64; and Radnor, 32. These are distinct from the aldermen and councillors in boroughs, who take no part in county administration.

The powers and duties which are given to the county councils by the Local Government Act, 1888, relate to county finance, rating and assessment, county buildings, bridges, lunatic asylums, reformatories, registration and polling of parliamentary electors, contagious diseases (animals), the appointment of coroners, maintenance of highways, preventing the pollution of rivers, and numerous minor matters. The control of the police is vested in the courts of quarter sessions and the county councils jointly. As regards its finances, each county council is empowered to make and levy county and other rates, and it will also receive its share of the income derived from certain license duties collected by the imperial government, together with a proportion of the probate duty collected in the United Kingdom.

County Rate.—The county rate is made under an Act 15 and 16 Vict. chap. 81, and is assessed, not on individual properties, but on the various parishes, and a precept is issued to the guardians of each union requiring them to pay to the county treasurer the aggregate amount of the sums payable by the parishes in their union. It can be expended only for 'county purposes,' which the county council is required to provide funds for in the execution of its powers as above enumerated.

County Boroughs.—By the Local Government Act, certain boroughs are exempted from the jurisdiction of the county councils of the counties in which they are situated, and are enabled to retain their independence, subject to certain special regulations for the adjustment of their financial relations with the counties. These boroughs are called 'county boroughs,' and are such as either were counties in themselves before the passing of the Local Government Act, 1888, or on the 1st of June 1888 had a population of not less than 50,000. They are as follows: Barrow, Bath, Birkenhead, Birmingham, Blackburn, Bolton, Bootle-cum-Linacre, Bradford, Brighton, Bristol, Burnley, Bury, Canterbury, Cardiff, Chester, Coventry, Croydon, Derby, Devonport, Dudley, Exeter, Gateshead, Gloucester, Halifax, Hanley, Hastings, Huddersfield, Hull, Ipswich, Leeds, Leicester, Lincoln, Liverpool, Manchester, Middlesbrough, Newcastle-upon-Tyne, Northampton, Norwich, Nottingham, Oldham, Plymouth, Portsmouth, Preston, Reading, Rochdale, St Helens, Salford, Sheffield, Southampton, South Shields, Stockport, Sunderland, Swansea, Walsall, West Bromwich, West Ham, Wigan, Wolverhampton, Worcester, Yarmouth, and York.

County Courts are sixty tribunals which have been established in the different counties of England for the hearing of cases of a minor importance relating to civil matters only. They are now regulated by the County Courts Consolidation Act, 1888, and under that statute can exercise jurisdiction in questions of law and of equity. Since their establishment in 1846 their powers have been gradually enlarged, and the tendency is to transfer cases in which the matters in dispute are not great from the higher courts to these courts. The registrar has power to take all undefended and

admitted cases by leave of the judge. In every action or suit of whatever nature where more than £5 is claimed, and in all other actions, by leave of judge, a jury may be demanded. The number of jurymen to try a cause in county courts is five. There is a right of appeal in all cases where more than £20 is claimed, and by leave of judge in all other cases. The judge only may commit to prison in cases where he is satisfied the debtor has the means to pay the debt or instalment thereof. There is no other ground of imprisonment for debt in county courts. A debtor may be committed for any period not exceeding forty-two days, and can be imprisoned only once for the same default.

In Scotland the tendency of the constitution under the feudal system was towards English methods of administration, and this brought about, among other innovations, the division into counties or shires. Its introduction seems to have begun early in the 12th century, and to have proceeded northwards. The crown at an early period adopted the practice of appointing Sheriffs (q.v.) in Scotland, and local judges for each county, and the system of appointing justices of the peace was introduced by James VI. There are now thirty-three counties in Scotland. The county organisation comprises a sheriff-principal (appointed by the crown for a county or a combination of counties), sheriff-substitutes, justices of the peace, commissioners of supply, county road trustees, and their officials. The Local Government Act, 1888, did not apply to Scotland or Ireland.

In Ireland the division into counties was begun in the time of King John, and it was not completed till that of James I. There are now thirty-two counties, each of which is divided into baronies. Its county organisation comprises the sheriff, the grand jury, justices of the peace, and officials. The grand jury consists of twenty-three persons, and is appointed under the Act 6 and 7 Will. IV., chap. 116. It is the principal county authority for purposes of local government, and its powers end with each of the assizes. The system of county government is thus seen not to be based on popular representation, as is the case in England and, to some extent, in Scotland.

In the United States the county is a creation of the legislature of each state, and is not a thing of gradual growth, as in England. Each county is invested with certain corporate rights and powers to enable it to perform the duties required of it in the machinery of government, and its affairs are managed by a board of commissioners or supervisors, who can levy and collect taxes and hold real and personal property for the benefit of the inhabitants. In every county there is a sheriff, coroner, treasurer, recorder of deeds, and registrar of wills. All officers are elected by the people. New counties are created by the subdivision of the existing counties. County courts exist in each county, but their powers vary according to the state they are in, some having very extensive common-law and equity jurisdiction, while others can deal only with small suits, and are limited to chancery jurisdiction and matters affecting trust properties.

For authorities, see Stubbs, *Constitutional History* (1874-78); Hallam, *Constitutional History* (1827; new ed. 1866); Freeman, *Norman Conquest* (1867-79); Gneist, *English Constitution* (trans. 1886); also LOCAL GOVERNMENT, and works there cited.

Coup is a French word signifying 'a stroke,' used in certain phrases that have become current in Europe. A *coup d'état* ('stroke of state') means an arbitrary encroachment suddenly effected by the governing authorities upon the constitution of the state, altering or setting aside the prerogatives of other parts of the body politic. The term is applied particularly to the treacherous but successful attack

COUPAR-ANGUS

upon the liberties of his fellow-countrymen by Louis Napoleon, 2d December 1851. *Coup de main* ('a stroke of the hand') is a sudden and successful attack; *coup d'œil* ('a stroke of the eye') is a summary view of a complicated matter; *coup de théâtre* is a trick of the stage; and *coup de grâce* is the merciful blow that puts a victim out of pain.

Coupar-Angus, a town chiefly in Perth but partly in Forfarshire, near the left bank of the Isla, a tributary of the Tay, 13 miles NNE. of Perth, and 15 NW. of Dundee. Here are remains of a Roman camp, within which is the fragment of a Cistercian abbey, founded by Malcolm IV. in 1164, and forming the subject of a monograph by Rogers and Allan (2 vols. 1879-80). Linen is manufactured. Pop. (1841) 1868; (1881) 2154. See also CUPAR.

Couped, or **COUPÉ**, in Heraldry, is used to describe the head, or any limb of an animal cut off in a straight line. It is distinguished from *erased*—i.e. forcibly torn off, and therefore ragged and uneven.

Couple is the name given in statics to a pair of equal forces acting on the same body in opposite and parallel directions. The effect of a couple is to rotate the body about a certain definite line (the axis) perpendicular to the plane in which the forces constituting the couple lie.

Couplet. Any two lines which rhyme together may be called a couplet; but the term is more frequently used to denote two lines which contain the complete expression of an idea, and are therefore to a certain extent independent of what goes before or what follows. The poetic wits of the age of Queen Anne excelled in this kind of aphoristic versification. Pope, as has been said, reasons in couplets. For example:

'Tis with our judgments as our watches, none
Go just alike, yet each believes his own.

However effectively epigrammatic short aphorisms may be expressed in rhymed couplets, a long poem in this rhythm becomes wearisome to the ear. Not all the alert genius of Pope, nor the sonorous strength of Dryden could avert from their favourite rhythm the damning sin of monotony.

Coupon (Fr., and from *couper*, 'to cut'), a term signifying any billet, cheque, or other slip of paper cut off from its counterpart. It is, however, applied chiefly to a dividend or interest warrant, which is presented for payment by holders of debentures. Coupons in Great Britain require to be stamped. The term is also applied to one of a series of tickets which are vouchers that certain payments will be made or services be performed, at various times or places, in consideration of money paid.

Courant (Fr.), the heraldic term for 'running.'

Courbet, GUSTAVE, painter, was born at Ornans, Franche-Comté, on the 10th of June 1819. In 1839 he was sent by his father, a well-to-do farmer, to study law in Paris, but all the bent of his singularly strong and self-assertive nature was turned towards art. He made himself acquainted with the Flemish, Florentine, and Venetian schools; but amid all he was careful to preserve—as he phrases it—his 'own intelligent and independent individuality.' In 1841 he took to landscape painting in the forest of Fontainebleau. In 1844 he began to exhibit at the Salon; and his works created a great sensation when shown in the Salon of 1850. Marred by frequent coarseness, and by defects of drawing, Courbet's works possess fine and powerful colour, and are valuable for their firm basis in actual fact, for their truth to an individual and personal impression of nature. His hunting scenes and animal subjects are especially vigorous and spirited. In 1869 he accepted the

Cross of the Order of St Michael from the king of Bavaria, and after the revolution of 1870 he was appointed Director of the Fine Arts. In the following year he joined the Commune, and was concerned in the destruction of the Vendôme Column (10th May), for which, in the following September, he was sentenced to six months' imprisonment, and to be fined for its restoration, his pictures being sold in 1877 towards that purpose. On his release he retired to Vevey in Switzerland, where he died, 31st December 1877. An exhibition of nearly two hundred of his works was brought together in the Ecole des Beaux Arts, Paris, in 1882. See the *Century* for February 1884.

Courbevoie, a town of France, on the left bank of the Seine, opposite the north-western suburbs of Paris. It has many handsome villas, a large barrack, bleaching-fields, and a carriage factory. Pop. (1896) 15,937.

Courier, PAUL LOUIS, one of the most powerful and brilliant of French writers, was born in Paris on January 4, 1772. His boyhood was spent in Touraine, and he afterwards studied at the Collège de France and the School of Artillery at Chalons. He then served for some eighteen years in the army, but his interest lay wholly in study, and especially in the study of the Greek language. His military experiences ended in 1809 on the field of Wagram, from which he was carried insensible to Vienna. Thenceforth he devoted himself to letters. He lived for some time at Florence, where he became embroiled with the librarian of the Laurentian Library, in regard to a manuscript of Longus. The quarrel led to the publication of the *Lettre à M. Renouard*, in which Courier's incomparable ironic faculty was for the first time revealed. He removed to Paris in 1812, and in 1814 settled on his estate at Touraine. In 1816 he issued the first of his famous pamphlets, the *Pétition aux Deux Chambres*, a scathing exposure of the wrongs inflicted on the peasantry by the government of the Restoration. The *Pétition* was read by high and low, and its author was thenceforth recognised as a political power in France. Courier continued the attack in a series of admirably witty letters in the *Censeur*, and in 1821 there appeared the inimitable *Simple Discours de Paul Louis, Vigneron de la Chavonnière*. In this pamphlet the scheme to purchase the estate of Chambord for the Duc de Bordeaux by a 'national offering,' wrung from the peasantry, was mercilessly derided and laid bare. The *Simple Discours* is Courier's masterpiece. It was made the subject of a government prosecution, and its author underwent two months' imprisonment in Sainte Pélagie, where he formed the acquaintance of Béranger. On his release he was again tried, but escaped with a reprimand, for his *Pétition pour les Villageois qu'on empêche de danser*. His subsequent writings were published anonymously at Brussels. They comprised *Réponses aux Lettres Anonymes*, the *Gazette du Village*, the *Livret de Paul Louis*, the *Pièce Diplomatique*—an imaginary letter from Louis XVIII. to the king of Spain—and the *Pamphlet des Pamphlets*, a vindication of pamphleteering, which appeared in 1824, and which Armand Carrel called 'the swan-song of Courier.' On Sunday, May 10, 1825, Courier was found shot dead a little before sunset in the grounds of his house at Varetz.

With the exception of Pascal, Courier is the greatest master of irony in the ranks of French authors. A deadly controversialist, he was at the same time an exquisite artist, whose style is characterised by austere simplicity of diction. See the notice of Courier in the edition of his works edited by Armand Carrel (4 vols. Paris, 1834), and an

admirable essay by Mr H. Traill in the *Fortnightly Review* of February 1877.

Couriers are persons hired to accompany travellers abroad, whose special duty is to make all arrangements for the journey, and relieve their employers as far as possible of all anxiety about passports, exchange of money, hotel negotiations, and the like. The speaking of several languages is one of many important qualifications in a good courier.—King's or Queen's Messengers are sometimes called Foreign Office couriers.

Courlan, an American wading-bird of the genus *Aramus*, usually placed among the Rails (q.v.). The North American courlan or crying-bird (*A. giganteus*) is 27½ inches long, with long bill and short wings, is a rapid runner, and has a cackling note. It inhabits Florida and the West Indies. The nest is usually attached to reeds. The flesh of the young is good eating. The South American courlan (*A. scolopaceus*) is larger.

Courland, or **KURLAND**, a Russian government, and one of what are called the Baltic provinces. It was formerly an independent duchy—properly, indeed, consisting of two duchies, Courland and Semgallia—and belonged, along with Livonia, to the Teutonic Knights. The difficulty of resisting the Russians led to the acknowledgment in 1561 of the feudal sovereignty of Poland. The country was long distracted by the contentions of two parties, one Russian and the other Polish; and after being for some time very completely under Russian influence, it was finally united to Russia in 1795. Biron (q.v.) was made Duke of Courland in 1737. It contains about 10,540 sq. m., with a population in 1883 of 637,028, mostly Protestants. It is generally a level country, with ranges of low hills, and contains many lakes, bogs, forests, and sand-dunes, but some parts have a very fertile soil. Cattle-breeding is on the increase; game abounds; and bears, boars, elks, and wolves are met with occasionally. The proprietors of land are mostly German; the peasantry, who constitute the bulk of the population, of Lettish extraction, are chiefly engaged in husbandry. The Russians do not amount to 2 per cent. of the population. There is little manufacturing industry, but trade is rather increasing. The capital is Mitau, but the most flourishing town is Libau.

Courses. See **SAILS**.

Coursing is defined by Dr Johnson as 'the sport of hunting hares, foxes, and sometimes deer with greyhounds.' From the sportsman's point of view foxes and deer must be eliminated from the definition, for coursing is now understood to be the pursuit of hares by a brace of greyhounds. The saying that 'a gentleman was known by his hawk, his horse, and his greyhound,' is a very ancient one; and King John is recorded to have accepted greyhounds in lieu of a money fine; but in those times it was generally deer that were coursed. In Elizabeth's reign the sport attained a fashion and celebrity previously unknown, and has since that time been followed up with undiminished zeal.

Late in the 16th century we have a record of some laws of the leash framed by the then Duke of Norfolk on principles which have been largely adhered to since. To Lord Oxford, the lord-lieutenant of Norfolk, the sport of coursing is much indebted. Indeed, by some he is called 'the father of modern coursing;' and he it was who founded the first society, as it was then called, in 1776 at Swaffham in Norfolk. Other clubs were soon organised, Lord Craven founding one at Ashdown Park in 1780, and this was followed by the Malton Club in Yorkshire and the Bradwell and Tillingham Club in Essex, besides many others

starting soon after the opening of the 19th century.

After the passing of the Game Laws in 1831 coursing became much more general, and the sport was taken up by the public, meetings prior to that time being principally supported by members of clubs, of which there were a large number spread over the kingdom. From that date up to 1875 the growth of coursing was very great, and all the chief meetings throughout England, Scotland, and Ireland were attended not only by those who owned dogs, but also by many who simply went for the love of the sport. It was feared by many that the Ground Game Act of 1880 would greatly interfere with public coursing, and this fear naturally caused coursers to follow the example of Mr Case, of Plumpton, who originated the inclosed system, the first ground being made over his farm in Sussex. Up to this time coursers as a body had looked rather askance at the new method of carrying on the sport; but the Ground Game Act caused more inclosures to be formed, and then the fact of their being so easy of access added greatly to their popularity.

The real sport of coursing can only be obtained at the open meetings, so called in distinction to the inclosed, notwithstanding that these latter fixtures have been for a time in favour with those who prefer the 'ease and comfort' obtained from commencing the day some time between eleven and twelve and finishing at four, whilst all the courses run can be witnessed from a grand-stand. At the inclosed fixtures the betting as a rule is far higher than when the coursing takes place in some open country where the slipper and dogs have to be followed from one end of the day to the other, for this would be far too much work for the ordinary betting-man.

At a coursing-meeting two Greyhounds (q.v.) are slipped together, and the judge who has been appointed by the committee or by the votes of the nominators decides which is the winner of the trial upon the one uniform principle that the greyhound which does most towards the killing—though he may not actually kill—is to be declared the winner. The judge has a recognised code of points to go by, these points being *speed*, for which one, two, or three points may be allowed; *the go-bye*, two or three points; *the turn*—that is, bringing the hare round at not less than a right angle—one point; *the wrench*—bringing the hare round at less than a right angle—half a point; *the kill*, one or two points or even less; and *the trip*—where the hare is thrown off his legs—one point.

Those fixtures held over the downs have always been looked upon as amongst the very best of the open meetings. The Amesbury meeting has always been held over the splendid range of Wiltshire downs belonging to the Antrobus family. The village of Amesbury, which is the headquarters for this fixture, is 7½ miles north of Salisbury. The Ashdown Park Club was established by the then Earl of Craven in 1780, and the stakes up to 1850 were confined to its members; but since that date open meetings have taken place in addition to others held by the South of England Club. The Berkshire village of Lambourn is the headquarters for the Ashdown meetings. Another favourite meeting is held over the Stockbridge Downs, a short distance from the well-known racecourse. The Waterloo Cup meeting takes place over the so-called Plains of Altcar (belonging to the Earl of Sefton) in Lancashire, and here, too, the Altcar Club holds its fixtures. The Ridgway Club meeting is another of the large and old-established Lancashire fixtures, but the running there is confined to members. The Clifton Arms Hotel at Lytham is the headquarters. Two meetings

are annually held at Southport. In Yorkshire the best meetings take place under the North of England Club, several estates being lent by the owners for their fixtures; and in addition Scarborough and other places annually hold open meetings. Lincolnshire has a well-managed fixture at Sleaford. In the Midlands Lichfield is the best supported meeting, the Marquis of Anglesey allowing the coursing to take place over his estate at Beaudesert. Newmarket—the turf metropolis—annually boasts of a large and well-attended meeting. Farther south the Cliffe and Hundred of Hoo Club and the Essex Club both hold open fixtures—the former over the Cliffe marshes beyond Gravesend, the Essex Club at Southminster.

The Border Union ranks as the best meeting held in the north, and this fixture, which now takes place in November, is much looked forward to by both northern and southern coursers. Longtown, $9\frac{1}{2}$ miles north of Carlisle, is the headquarters. The principal meetings in Scotland are Carmichael and Corrie. In Ireland, Mourne Park may be said to be the chief meeting (though really coming under the head of 'inclosed'), many English dogs being sent across the Channel to compete, and the coursing season is always opened there. Other fixtures are held by the Northern Club and the Leinster and Limerick clubs.

The first ground over which 'inclosed' coursing took place in 1876 was at Plumpton in Sussex. Here originally there were three fields, with plantations for letting the hares out from and escape coverts made at the farther end; but the smallest of these inclosures was soon done away with, and the sport took place over the Station Field, which was 800 yards long by 300 yards wide, and the Hill Field, 700 yards by 300 yards. Since 1886, however, the Station Field only has been used; and this is on an incline from one end to the other, affording good trials, and fairly well testing both the speed and stamina of the greyhounds. In connection with High Gosforth Park an inclosure was made 5 miles from Newcastle-on-Tyne. The coursing-ground is slightly down hill from the slipping station for about 150 yards, and from that point a very easy rise to the escape covert. At Haydock Park, near Newton Bridge station, on the Liverpool and Manchester Railway, are two fields quite distinct, which are used on alternate days, so that the same hares are not coursed two days in succession.

Kempton Park, the nearest inclosed ground to London, is situated in the Vale of Sunbury, $16\frac{1}{2}$ miles from the metropolis. Two meetings a season are held here, and the champion meeting which annually takes place in January holds the highest rank in this style of coursing. All the fastest dogs in the United Kingdom are brought together, for, as a rule, it is to the dog with the most speed that the chief prizes in the inclosures fall, the working qualities of the greyhound not being sufficiently brought into play.

At Wye, near Ashford in Kent, an inclosure has been established, and meeting after meeting takes place here throughout the season, with at times a very small interval between them. Here the ground is on the incline nearly all the way, and this, as a rule, gives the slower greyhounds a better chance of gaining the judge's verdict, as, though generally led, they when once in possession go the better with their game. The average number of points made in a course here are certainly greater than at the other inclosures. The inclosure at Four Oaks Park, about a mile from Sutton Coldfield, is another that is almost all on the incline, but the meetings here are now few and far between. The coursing arena is 700 yards in length, and 400 yards in width.

Court, PRESENTATION AT. Formal presentation to the sovereign of persons whose status entitles them to that honour, takes place either at St James's Palace, at a levee, intended for gentlemen only, or at Buckingham Palace, a drawing-room, where both ladies and gentlemen appear. The days when levees and drawing-rooms are to be held are always announced some time beforehand. It is difficult in the present day to define exactly who may and who may not be entitled to be presented. Members of families of the nobility and landed gentry, diplomats, members of the House of Commons, persons holding high offices under the crown, judges, magistrates, church dignitaries, officers in the army and navy, persons who have attained distinction by eminence of any kind, and the wives and daughters of the same classes, form the larger number of those presented at levees and drawing-rooms. Persons are often presented on entering on some office, or attaining some dignity. Any one who has been once presented is entitled to appear at any future levee or drawing-room without a new presentation. The whole arrangements connected with presentations are under the supervision of the lord chamberlain, in whose office in St James's Palace information is given to all persons wishing to be presented. The names of ladies and gentlemen desiring presentation, and of the ladies, noblemen, and gentlemen who are to present them, have to be submitted to the sovereign for approval, and there is a strict exclusion of persons of damaged reputation, whatever their rank. Court dress or official uniform must be worn. A British subject who has been presented at St James's may on any after occasion claim to be presented by the British minister at any foreign court. As to court dress both of ladies and gentlemen, court etiquette, court mourning, &c., reference may be made to *Old Court Customs and Modern Court Rule*, by the Hon. Mrs Armytage (1883).

Courtallum (Küttälum), a town of the district of Tinneveli, Madras, stands amongst the Ghats near the southern end of the peninsula; and though only 450 feet above sea-level, serves as the sanatorium of the district, deservedly enjoying a reputation for salubrity of air, richness of vegetation, and beauty of scenery. Pop. (1881) 1216.

Courtesy, or **CURTESY**, in Law, is the life interest which the surviving husband has in the real or heritable estate of the wife. Both in England and in Scotland this customary right has been regarded as a national peculiarity. Littleton speaks of it as tenure 'by the curtesie of England, because this is used in no other realme but in England only.' In Scotland it is called the courtesy or curiality of Scotland. It was probably introduced into both countries from Normandy. The four circumstances which are requisite to make a tenancy by courtesy in England are—marriage, seizin of the wife, living issue, and the wife's death. The rule that the child must have been heard to cry, which at one time was followed in England, is still adhered to in Scotland. It is not necessary, however, in either country, that the child survive; it is enough that it was once in existence, although it should have died immediately after its birth. In both countries, the child must be the mother's heir, and it is consequently said that courtesy is due to the surviving husband rather as the father of an heir than as the widower of an heiress.

Courtesy Titles are titles allowed to certain near relations of peers by understood usage and the courtesy of society, but to which the users have no legal right. The subject of courtesy titles, though tolerably familiar in its general outline to persons resident in Britain, is complicated

enough to be a frequent source of perplexity to Americans and foreigners, and may be thus explained: Dukes, marquises, earls, and even viscounts are often in possession of a number of titles belonging to an inferior grade in the peerage, which have in many cases been gradually accumulated by the ancestors of the peer in the course of his upward progress in the peerage. Some peers have as many as sixteen inferior titles—e.g. the Duke of Athole, who has one marquise, four earldoms, three viscounties, and eight baronies. While in ordinary parlance a peer is known by his highest title (or titles, if he holds two of the same degree), his eldest son bears by courtesy one of his inferior titles. Thus the eldest son of the Duke of Devonshire is Marquis of Hartington; of the Duke of Buccleuch and Queensberry, Earl of Dalkeith; of the Marquis of Bute, Earl of Dunfries. There is no rule as to which inferior title should be assumed, a lower one being occasionally preferred to a higher; and the courtesy title may be different in one generation from another. The inferior title of a viscount who is also a baron is never borne as a courtesy title by his son; but a usage prevails among viscounts and barons (more properly 'lords') in the peerage of Scotland, of the eldest son designing himself 'master'; thus the eldest sons of Viscount Arbutnot and Lord Lovat are known as the Master of Arbutnot and Master of Lovat. Courtesy titles are allowed to the eldest sons of courtesy marquises and earls. Thus the eldest son of Earl Percy, himself eldest son of the Duke of Northumberland, is Lord Warkworth. There are various instances of titles borne by heirs-apparent or grandsons of peers which have no existence among the family honours, or are derived from them by some modifications. While Earl Nelson's inferior titles are Viscount Merton and Baron Nelson, his eldest son is known as Viscount Trafalgar. There are a few cases where, in consequence of the inferior title being identical with the higher one, the eldest son substitutes the family surname for the title. The Earl of Gosford, whose family surname is Acheson, is also Viscount Gosford and Baron Gosford; and his son adopts the courtesy style of Viscount Acheson. The holders of courtesy titles, not being legally peers, can sit in the House of Commons.

The younger sons of dukes and marquises have the courtesy title of 'Lord' prefixed to their Christian name and surname—e.g. Lord Charles William de la Poer Beresford, second son of the late Marquis of Waterford; and the daughters of dukes, marquises, and earls, have 'Lady' followed by their Christian name and surname, the surname being that of their husband if married, or his courtesy title if he be a courtesy peer. But if a lady enjoying such courtesy title marry a peer (not by courtesy), she only takes her husband's peerage title. Thus the fifth Duke of Buccleuch's second daughter, by her marriage with Donald Cameron of Lochiel, became Lady Margaret Elizabeth Cameron, while the same duke's eldest daughter is Marchioness of Lothian. Lady Emily Somerset, daughter of the Duke of Beaufort, on marrying Viscount Dupplin, eldest son of the Earl of Kinnoull, was known as Lady Emily Dupplin; but on her husband succeeding his father as Earl of Kinnoull, she became simply Countess of Kinnoull, this change of designation involving, curiously enough, a loss of precedence, inasmuch as the rank of a duke's daughter is higher than that of a countess. When, as often happens, a royal warrant is granted to the brothers and sisters of a peer whose father has never been in possession, giving them the precedence of the sons and daughters of a peer, they enjoy the corresponding courtesy titles. The title 'Honourable,' used by sons of earls, viscounts,

and barons, and daughters of barons, belongs, not of courtesy, but of right, to them in common with all sons and daughters of peers.

The widow of a peer or a knight is allowed by courtesy to retain the title she acquired from her husband, notwithstanding a second marriage; the widow of a baronet is legally entitled to do so.

Along with courtesy titles may be ranked the appellations of the judges of the Court of Session in Scotland, who prefix 'Lord' either to their surname or to a territorial designation. These titles, though given in general society as well as on the bench, are not used in subscribing the judge's name, even to official papers. Hence Lord Medwyn's signature, 'J. H. Forbes,' and Lord Mure's, 'David Mure.' The wives of judges do not participate in their husband's titles. See ADDRESS, FORMS OF.

Court-fool. See JESTER.

Court-hand, a name given in England to a modification of the Norman handwriting, as distinguished from the modern or Italian handwriting which was in use in the English law-courts from the 16th century till abolished by law in the reign of George II. See WRITING.

Court-martial, a court for the trial of all persons subject to military law or to the Naval Discipline Act. In the army, before the institution of a standing army in 1660, military discipline was maintained by articles of war issued by the crown, to remain in force only so long as the campaign continued. These ordinances were administered by the Court of Chivalry (q.v.), of which the judges were the Lord High Constable and the Earl Marshal. In 1689 the first Mutiny Act (q.v.) was passed by parliament, and, with the articles of war, made by royal prerogative, constituted the law under which discipline in the army was maintained. This law, which is now embodied in the Army Act of 1881, provides for the assembly of courts-martial for the trial of offences which are of too grave a character to be dealt with summarily by the regimental commanders. They are of five kinds—general, district, regimental, field-general, and summary. The sovereign issues a warrant authorising each general officer to convene the two first named, and every regimental commander has power, in virtue of his office, to convene the third. The fourth can only be convened in countries beyond the seas, and to try offences against the person or property of an inhabitant when an ordinary general court-martial cannot conveniently be assembled. The last can only be convened on active service under similar conditions, and, with the fourth, has the same powers as a general court-martial.

A general court must consist of five officers (nine in the United Kingdom, India, Malta, and Gibraltar), including the president, who must be the senior and a field-officer, except in special circumstances, when a captain may preside, and each member must have held a commission for three years. Similarly, a district court must consist of three or five officers of two years' service, and a regimental court of three officers of one year's service; if no captain is available, a lieutenant may preside over either of them. All members must be strictly impartial, and may be challenged by the prisoner on that point. A field-general court must consist of three officers, of any rank, and a summary court of the same number, if available, otherwise two are sufficient; but in that case it cannot pass sentence of death, and, with three members, all must concur in such a sentence.

Any of these courts is competent to try any offence, but not any offender; thus an officer or

a civilian subject to military law, and on the same footing as an officer (e.g. a newspaper correspondent) can only be tried by a general, field-general, or summary court-martial, and a warrant-officer cannot be tried by a regimental court. Their powers of punishment vary also, from forty-two days' imprisonment to death. An officer may be sentenced to cashiering, dismissal, forfeiture of rank, or reprimand; a non-commissioned officer to reduction to the ranks, and like a private soldier, to discharge with ignominy, forfeiture of service, medals, &c., fines and stoppages of pay; all ranks and civilians, if subject to military law because accompanying a force on active service, may be sentenced to imprisonment, penal servitude, or death.

All sentences must be confirmed before they are carried out—those of general, field-general, and district courts by the sovereign, or officer authorised to confirm by warrant from Her Majesty; those of regimental and summary courts by the convening officer. The confirming authority may commute, mitigate, or remit the whole or part of a sentence, and may order both finding and sentence to be revised (unless the prisoner is acquitted), but cannot, nor can the court on revision, increase the sentence.

The procedure is similar to that of civil courts—the court is public, and the same rules of evidence are in force; but the members of a court-martial act as both jury and judge—i.e. they find the facts and allot the sentence. All are sworn, and each votes, commencing with the junior, both on the finding and sentence, as well as on any question that may arise, the majority deciding. The witnesses are also sworn. An officer is appointed as judge-advocate in important trials, to assist the court on points of law, see that the proceedings are regular, and, with the president, take care that the prisoner is treated with strict fairness. Counsel may appear on both sides at general courts, and, if barristers or officers subject to military law, may address the court, and examine and cross-examine witnesses; or before any court the prisoner may be assisted in his defence by a 'friend,' who may make suggestions to him, but is not allowed to address the court or the witnesses. The prosecutor must be an officer and not a member of the court; he is sworn, and charged with the duty of eliciting the truth, but not necessarily of obtaining a conviction. The proceedings are all written, except those of summary courts, which have a necessarily abbreviated form of procedure, like the drum-head court-martial for which they have been substituted.

Contempt of a court-martial by persons subject to military law is punishable by the same or another court-martial, and, in the case of civilians, by a civil court, to which the offence is certified by the president. Witnesses are summoned by the convening officer or the president, and, if civilians, their travelling expenses must be tendered. Sometimes courts of inquiry are held instead of a court-martial, not to try or to punish, but to make an investigation; the members not being on oath. Such a court occasionally precedes a court-martial.

On board a man-of-war no military court-martial may sit except a regimental court, with the sanction of the captain of the ship, for the trial of a non-commissioned officer, and it may only sentence him to reduction to the ranks. Marines are liable to trial by military court-martial when not borne on the books of a man-of-war, in which case they come under the Naval Discipline Act. Naval courts-martial consist of admirals, captains, and commanders, who try offences against the Naval Discipline Act. The chief admiral of the fleet or squadron appoints the members; but all captains on the station have a right to sit, if not implicated.

The court-martial is open to all the crew and others as spectators. The sentence is final, and needs no confirmation.

Courtney, LEONARD HENRY, was born at Penzance, in Cornwall, the son of a banker there, July 6, 1832. Educated at Penzance and St John's College, Cambridge, he graduated second wrangler and first Smith's prizeman in 1855, and became fellow of his college the year after. In 1858 he was called to the bar, and from 1872 to 1876 he filled the chair of political economy at University College, London. He early began to write for the *Times*, and his pamphlets and articles to monthly magazines placed him among the ablest and most advanced *doctrinaire* Liberals in England. He early became an eager advocate for proportional representation and a wide extension of local government. He was returned for Liskeard in 1876, and in 1885, and again in 1886, for South-east Cornwall. He was Under-secretary of State first in the Home and next in the Colonial Office, and in May 1882 succeeded the ill-fated Lord Frederick Cavendish as Financial Secretary to the Treasury. He was appointed chairman of committees in both the parliaments of 1885 and 1886.

Court of Session, the supreme court of civil jurisdiction in Scotland, was constituted in 1532. The credit of its origin is generally ascribed to the Duke of Albany, who when regent had submitted a scheme for the establishment of such a court to Pope Clement VII.; and the details of the scheme were carried out by Archbishop Dunbar of Glasgow, who was then Lord Chancellor. Its constitution was principally modelled on that of the parliament of Paris, of which body the Duke of Albany was at that time a member. French influence was clearly seen in many features of the Court of Session, and to this day may be recognised in the names of its officers—president, king's advocate, advocates, dean of faculty, procurators, &c. The judges of the Court of Session originally consisted of the Lord Chancellor, Lord President, and fourteen ordinary judges or 'senators of the College of Justice,' together with an indefinite number of extraordinary lords, who represented the peerage. At first, half the number of the judges were laymen appointed by the king, and half ecclesiastics appointed by the church. In 1584 all clergymen were declared disqualified from holding judicial office, but so late as 1664 the Archbishop of Glasgow was made an extraordinary lord. The extraordinary lords themselves were abolished in 1723, and the Court of Session then consisted of the Lord President and fourteen ordinary judges, the office of Lord Chancellor having been abolished at the Union. The Court of Session first sat in the Tolbooth or prison of Edinburgh, but in 1639 was accommodated in the buildings of the Parliament House, which was then erected. It sat as one chamber, one of the ordinary lords going by rotation weekly to sit in what was called the Outer House. Here all cases, with certain exceptions, were in the first place heard and decided by the Lord Ordinary, but an appeal lay from his judgment to the whole court. Fresh changes were made in 1808 and 1810; and in 1830 the total number of judges was reduced to thirteen, the two divisions each consisting of four, including the Lord President and Lord Justice-clerk, whilst the number of the Outer House judges remained as before: this is the present constitution of the court. In 1830, moreover, the office of president was united with that of Lord Justice-general or president of the High Court of Justiciary (q.v.), the supreme criminal court in Scotland. Prior to 1887 five of the judges were appointed Lords Com-

missioners of Justiciary, but by the Criminal Procedure (Scotland) Act of that year all the judges are now members of that court. Since the Union in 1707, several courts which had a separate existence, and in some cases an exclusive jurisdiction, have been merged in the Court of Session. These are the Court or Commission of Teinds (though this still sits nominally as a separate court), in which questions relating to the law of teinds or church tithes were decided; the High Court of Admiralty, dealing with maritime cases; the Court of Exchequer, having jurisdiction in all matters relating to crown rents, customs, &c.; and the Commissary Court of Edinburgh, which had to do with wills. The judges of the Court of Session are appointed by the crown from the bar, and hold their offices *ad vitam aut culpam*. See APPEAL, JUSTICIARY (COURT OF).

Court-plaster. See PLASTER.

Courtrai (Flem. *Kortrijk*), a town of Belgium, in the province of West Flanders, 54 miles SW. of Brussels by rail, and 6 miles from the French frontier. Courtrai, which is built on both sides of the Lys, is surrounded with ancient walls, and has a fine old bridge flanked with Flemish towers, a noble town-hall (1526), belfry, and a beautiful Gothic church, founded in 1238 by Baldwin, Count of Flanders. Table damask, linen, and lace are the principal articles of manufacture, and employ 5400 hand-loom and several large factories. There are extensive bleaching-grounds in the vicinity, and the neighbouring plains supply fine flax in large quantities to many European markets. Pop. (1875) 27,076; (1887) 29,307. In 1302 the Flemings, citizens of Ghent and Bruges chiefly, won a splendid victory over the chivalry of France beneath the walls of Courtrai, called 'Battle of the Spurs,' from the number of gilt spurs afterwards gathered from the dead by the victors. Henry VIII.'s 'Battle of the Spurs' was fought at Guinegate (q.v.) in 1513.

Courts of Law. See COMMON LAW, CHANCERY, EQUITY, APPEAL, HIGH COURT OF JUSTICE, COURT OF SESSION, COUNTY COURTS, ADMIRALTY COURT, DIVORCE COURT, &c.

Cousin (Fr. from Low Lat. *cosinus*; for Lat. *consobrinus*), a kinsman; more specifically the son or daughter of an uncle or aunt. The children of brothers or sisters are *cousins-german* (German being the Lat. *germanus*, 'brother'). The children of cousins-german are *second cousins*; and if A and B are cousins, A is a *first cousin once removed* to the children of B, as B is to the children of A. See CONSANGUINITY.

Cousin, VICTOR, the founder of systematic eclecticism in modern philosophy, was born in Paris, November 28, 1792. He studied with brilliant success at the Lycée Charlemagne and the École Normale. He was attracted to the study of philosophy by Laromiguière, a disciple of Locke and Condillac; but appointed in 1815 assistant-professor to Royer-Collard at the Faculty of Letters, he threw himself heartily into the reaction against the sensualistic philosophy and literature of the 18th century. Following the path of his senior, he became an exponent of the doctrines of the Scottish metaphysicians, but exhibited far more brilliancy than the original authors of these doctrines. In 1817 Cousin visited Germany, and already introduced to its bolder speculative systems, he now zealously studied Kant, Jacobi, Fichte, Schelling, and Hegel. For his liberalism he was in 1821 deprived of his offices; and in a second visit to Germany in 1824-1825, suspected of carbonarism, he was arrested at Dresden, presumably at the instigation of the French police, and sent to Berlin, where he was detained for six months.

He took advantage of his compulsory residence in the capital of Prussia further to study the philosophy of Hegel. On his return to France he took a decided stand against the reactionary policy of Charles X., and in 1827 was reinstated in his chair at the Sorbonne. Meanwhile he had appeared as an author. During 1820-27 he published his editions of Proclus and Descartes and part of his celebrated translation of Plato. It has been said that to find an audience as numerous and as passionately interested as were those of Cousin, it would be necessary to go back to the days of Abelard. Cousin threw great moral earnestness into his work; his doctrines were for the most part new to his hearers, bold, and in harmony with the spirit of the time. The finest qualities of the national genius appeared in his lectures, a wonderful lucidity of exposition, a beauty of style such as few philosophers have equalled, and a power of co-ordinating the facts of history and philosophy in such a manner as to make each illustrate the other. At this period Cousin was one of the most influential leaders of opinion in Paris; and consequently, after the revolution of 1830, when his friend Guizot became prime-minister, Cousin was made a member of the Council of Public Instruction; in 1832 a peer of France; and later, Director of the École Normale. The great success of his efforts for the organisation of primary instruction was largely a consequence of those valuable reports which he drew up, from personal observation, on the state of public education in Germany and Holland. In 1840 he was elected a member of the *Académie des Sciences Morales et Politiques*, and in the same year became Minister of Public Instruction in the cabinet of Thiers. The revolution of 1848 found in Cousin a friend rather than an enemy, and he aided the government of Cavaignac. After 1849 he disappeared from public life. In his last years he lived in a suite of rooms in the Sorbonne, and he died at Cannes, 13th January 1867.

His philosophy is eclecticism, but not mere syncretism. He has a definite criterion of truth, and a definite method of observation, analysis, and induction; his system comprises psychology, ontology, and an eclectic history of philosophy. Psychological observation gives three great factors—sensibility, activity or liberty, and reason, the latter being impersonal. Cousin repudiates pantheism, with which he has often been charged; and criticising the opposing systems of sensationalism, idealism, scepticism, and mysticism as incomplete rather than false, he holds that each expresses a real order of phenomena and ideas. Cousin's influence revived the study of philosophy in France, and especially renewed interest in the history of philosophy. Amongst his pupils more or less influenced by his teaching are Jouffroy, Rémusat, Barthélemy, St Hilaire, Jules Simon, and Janet.

Cousin's chief works (besides those already mentioned) are *Fragments Philosophiques* (1826), *Cours de l'Histoire de la Philosophie* (1827), *Cours d'Histoire de la Philosophie Moderne* (1841), *Cours d'Histoire de la Philosophie Morale au XVIII^e Siècle* (1840-41), *Leçons de Philosophie sur Kant* (1842), *Études sur les Femmes et la Société du XVII^e Siècle* (1853), his famous *Du Vrai, du Beau, et du Bien* (1854; 23d ed. 1881), works on Aristotle, Locke, Kant, and Pascal, and his editions of Abelard and Pascal's *Pensées*. See ECLECTICISM; Sir William Hamilton's famous critique on the *Discussions*; Janet, *Victor Cousin et son Œuvre* (1885); and Jules Simon's brilliant Monograph (1887; translated by G. Masson, 1888).

Cousins, SAMUEL, engraver, was born, 9th May 1801, at Exeter, and early began to draw with the pencil. He was apprenticed to S. W. Reynolds, the excellent mezzotinter, in many of

whose plates he had a chief hand, while some fifty-five of the small mezzotints after Sir Joshua, which bear his master's name, were his work. About this period he also executed portraits in pencil. In 1826 he started on his own account as an engraver, and produced the 'Master Lambton' after Lawrence, a mezzotint which at once established his reputation. It was followed by a long series of admirable plates after Reynolds, Lawrence, Landseer, Leslie, Millais, Leighton, and other eminent painters. His 'Marie Antoinette in the Temple,' after E. M. Ward, he was accustomed to rank as one of his finest works. He was elected an Associate-engraver of the Royal Academy in 1835, and a Royal Academician Engraver in 1855, and he retired in 1880. To the Academy he presented a sum of £15,000 to found annuities for poor and deserving artists. He died 7th May 1887. His works were catalogued by Algernon Graves in 1880.

Coutances, a town in the French department of La Manche, 5 miles from the English Channel, and 57 S. of Cherbourg by rail. It stands on a hill crowned by the cathedral (dating from the 13th century), one of the finest specimens of ecclesiastical architecture in the Early Pointed style in Normandy. Pop. 8108.

Couthon, GEORGES, a fanatic of the French Revolution, was born in 1756 at Orcet, near Clermont, in Auvergne. An advocate at the outbreak of the Revolution, he was sent by Puy de Dôme to the National Convention, where, spite of his crippled limbs, he made himself conspicuous by his shrieking hatred of the priesthood and the monarchy. He voted for the death of the king without delay, became a devoted and bloodthirsty partisan of Robespierre, and was appointed in July 1793 a member of the *Comité de Salut Public*. At Lyons he crushed the insurrection with merciless severity, and outlived himself after his return to the Convention, with his frothy ravings against Pitt and the English nation. The fall of Robespierre brought down Couthon also. Accused by Fréron, he was thrown into prison, delivered by the mob with whom he was popular, recaptured by the soldiers of the Convention, and executed 28th July 1794, along with St Just and Robespierre.

Contras, a town in the French department of Gironde, on the left bank of the Dronne, 32 miles NE. of Bordeaux by rail, with some trade in flour and wine. Here, in 1587, Henry of Navarre gained a bloody victory over the forces of the League, under the Duc de Joyeuse, who perished. Pop. 2202.

Coutts, THOMAS, banker, was born in 1735 in Edinburgh, the son of a merchant and banker, who was lord provost in 1742-44. With his brother James he founded the banking-house of Coutts and Co. in London, and on the latter's death in 1778 became sole manager. Keen and exact in matters of business, although charitable and hospitable in private, he left a fortune of some £900,000 at his death in 1822. By his first wife, who had been a servant of his brother's, he had three daughters, who married respectively the Earl of Guilford, the Marquis of Bute, and Sir Francis Burdett, Bart.; in 1815 he married Miss Mellon the actress. See BURDETT-COUTTS.

Couvade, a singular and widespread custom among savages in many parts of the world, and regulating the conduct of a father in connection with the birth of a child. In Guiana, even before the child is born, the father abstains from some kinds of animal food. The mother works up to a few hours before the birth, and retires alone, or with some women, to the forest for the birth. In a few hours she returns and resumes her ordinary work.

Meanwhile the father has taken to his hammock, and abstains from every kind of work, from meat and all other food except weak gruel of cassava meal, from smoking, from washing himself, and especially from touching weapons of every kind. During this time, which may extend for weeks, he is fed and cared for by the women. The explanation is unattainable; but the custom appears to imply a mysterious magical and sympathetic connection between father and child, such that if the father infringe the rules of couvade the child suffers. If he eat capybara flesh, the child will have protruding teeth like those of that animal; if he eat an animal with spotted skin, the child will be spotted too. In Guiana the child is not weaned till the third or fourth year. Indians often allege in explanation that the child descends more directly from father than from mother. Some recent anthropologists find the origin of the custom in the transition from the original matriarchal system (see *TRIBE*), in which descent and inheritance were reckoned through the mother alone, to the patriarchal system. In some places still the father has to buy the child from the mother; among the ancient Romans, the father had to lift the child from the ground. The couvade may therefore be a ceremony by which the father secures and proclaims his property in the new-born child. Diodorus records the custom as in use among the ancient Corsicans; and it has been found by ancient and modern travellers in parts of China, Borneo, Africa, North and South America. The name, now commonly used by anthropologists, is French, being from *couver*, 'to hatch eggs.' See Tylor, *Early History of Mankind* (1878); Giraud-Teulon, *Les Origines de la Famille* (1874).

Covenant (Lat. *convenire*, 'to come together'), a contract or agreement; a term much used by theologians, and in its ordinary signification, as well as in its theological use, nearly if not always exactly equivalent to the Hebrew *berith* of the Old Testament and the Greek *diathēkē* of the New. Applied to relations established between God and men, the term covenant must be understood with a certain modification of the meaning which it bears when employed concerning the relations of men to one another, when two independent parties enter into a covenant, which they have equal right to make or to refuse to make; and is sometimes employed as equivalent to *dispensation*, and the Jewish dispensation is called the *Old Covenant* (or *testament*, by another translation of *diathēkē*), in contradistinction to the Christian, which is called the *New* (see *BIBLE*). The 'Covenant' or 'Federal' system of theology was developed by Cocceius (q.v.). God, in his supremacy, is regarded as appointing certain conditions for his creatures, which they cannot but accept, yet their willing consent to these conditions gives to the relation established the nature of a covenant; and thus God is commonly said to have made two covenants with man—the *first covenant*, or *covenant of works*, with Adam, as the representative of the whole human race, promising life (with perfect happiness), upon condition of perfect obedience, whilst death was threatened as the penalty of transgression; the *second covenant*, or *covenant of grace*, being that on which depends the whole hope and salvation of man since the first covenant was broken, and in which life is freely offered to sinners, and they are simply required to believe in Jesus Christ that they may be saved. This covenant God is regarded as having made with Christ, as the representative of his people, and with them in him. The older theologians often speak of the *covenant of redemption* between God and Christ, employing the term *covenant of grace* rather to designate the whole dealings of God with men in

giving effect to the covenant of redemption; but the term *covenant of grace* has long been almost universally employed to include all that was comprehended under both terms. The *Abrahamic covenant* is the covenant of grace as declared to Abraham, in its particular relation to him and his seed. God is represented in Scripture as sustaining a *covenant relation* to his *own people*, to the Jews under the Old Covenant, to believers in Christ under the New; and doctrinal theology consists not a little in tracing out the nature of this relation, and the consequences which flow from it. As the people of God collectively sustain a covenant relation to him, so do believers individually; and it has not been an uncommon thing for pious persons to endeavour to reduce to writing their sense of this *covenant obligation*, under the notion of a *personal covenanting* with God; and of binding themselves by a stronger obligation to what they believed to be good and their duty. It has also been common for men, from the earliest ages, to enter into covenants with one another with more or less of religious solemnity; and this has in particular been done among those who have suffered persecution, or have been engaged in contests concerning matters of religion, for which the authority of certain passages of the Old Testament is strongly pleaded. Instances occur in the history of the Waldenses, and of some of the Reformed churches, particularly in Scotland.

THE COVENANTS, known in Scottish history and tradition, originated in the Reformation movement of the 16th and 17th centuries. The first Reformation, in 1560, was preceded by several religious bonds among the Reformers themselves; but the work of reformation was crowned in both first and second periods by the whole nation engaging in public religious covenanting. These public national covenants are two in number—the National Covenant, and the Solemn League and Covenant.

The *National Covenant*, which is sometimes called the 'Scots Confession' and the 'Short Confession,' to distinguish it from the more elaborate Confession of Faith enacted and placed on the statute-book by parliament in 1560, was drawn up in 1580, at the command of James VI., by one of his chaplains, John Craig (q.v.), to counteract attempts which were being made by the Roman Catholics to regain their lost hold of Scotland. It contains a profession of adherence to the 'true Christian faith and religion' more particularly expressed in the Confession of 1560, an explicit renunciation of the tenets of popery, which are detailed at length, and a pledge of obedience to the Presbyterian discipline of the church as then established, and of allegiance to the king in the defence of the gospel, all being ratified by solemn oath. By the ordinance of the king, the Privy-council, and the General Assembly, this Covenant was sworn and subscribed by all ranks and classes in 1581; renewed in 1590 in a bond specially directed against the machinations of the Holy League, which had in 1588 despatched the Armada against the British Isles; again renewed in 1596, and still again in 1638. In the last-mentioned year it was renewed in a bond directed against the attempts of Charles I. to enforce the Laudian service-book and Episcopacy upon Scotland. The swearing and subscribing of the Covenant throughout the country was inaugurated in the Greyfriars' Churchyard at Edinburgh, on 28th February; numerous copies were then sent out over the country, and of these many are still extant both in private and public custody. In the library of the Faculty of Advocates at Edinburgh alone, no fewer than five parchment copies are preserved with the original signatures of Rothes, Montrose, Loudoun, and many others of the nobility, gentry,

commissioners of counties and burghs, and ministers. Only one of these, however, is connected with the year 1638. At the meeting of the General Assembly in Glasgow, on 21st November of that year, the Covenant was ratified and appointed to be again sworn, while in pursuance of the object of the Covenant, the assembly deposed the whole of the Episcopal hierarchy which had been established by James VI. The other four copies of the Covenant above referred to were subscribed in 1639. The Covenant was further ratified by the parliament of Charles I., held at Edinburgh, June 11, 1640; and it was subscribed by Charles II. on his landing in Scotland, at Speymouth, on June 23, 1650, and again at his coronation at Scone, on January 1, 1651.

The *Solemn League and Covenant* was in effect an international treaty between Scotland and England, for the object of securing the civil and religious liberties of these kingdoms. In 1643 commissioners were sent by the parliament to Edinburgh to solicit the assistance of the Scots on the basis of a treaty between the two kingdoms. To this the Scots Convention of Estates and also the General Assembly cordially assented, on condition that the treaty was drawn up in the interests of their religious as well as their civil liberties. Committees of both were appointed to meet with the English commissioners, and the result of their deliberations was the Solemn League and Covenant. It is believed to have been largely the work of Alexander Henderson. It was hailed by both the representative bodies of the Scots with joyful unanimity, and sent to England for approbation, with their warmest recommendations and assurances that it would prove 'the most powerful means, by the blessing of God, for settling and preserving the true Protestant religion with perfect peace in all his majesty's dominions, and propagating the same to other nations, and for establishing his majesty's throne to all ages.' It was received with almost perfect unanimity by the English parliament and the Westminster Assembly of Divines, both of whom forthwith swore and subscribed it, and sent copies over the kingdom, with their ordinance that it should be subscribed and sworn by all. Zachary Crofton gives a list of 793 ministers in twelve only of the counties of England, the West Riding of Yorkshire, and the city of London who subscribed their adherence to the Covenant. As soon as intimation of its acceptance by England was received in Scotland, the Solemn League and Covenant was enjoined to be sworn there by all ranks and classes; and being sent to Ireland was embraced by the Protestants there with like eagerness and satisfaction.

The prime object of the Solemn League and Covenant, as stated in the preamble thereof, was 'the preservation of ourselves and our religion from utter ruin and destruction,' and the Covenanters pledged themselves, in their places and callings, to endeavour the preservation of the reformed religion in the Church of Scotland, and the reformation of religion in England and Ireland, in the way of securing a uniformity of religion in the three kingdoms, in doctrine, worship, discipline, and government. There can be little doubt that Presbyterianism was intended, as prelacy, which had just been abolished by both English and Scottish parliaments, was specially marked for extirpation along with popery. The Covenanters also pledged themselves to 'preserve the rights and privileges of the parliaments,' to 'defend the king's majesty's person and authority in the preservation and defence of the true religion and liberties of the kingdoms,' to endeavour that the three kingdoms might 'remain conjoined in a firm peace and union to all posterity,' and finally, to evince a thorough and real reformation of life both in public and in private.

Solemn League and Covenant was renewed in Scotland in December 1648, and along with the National Covenant was sworn to and subscribed by Charles II. at Speymouth and Scone. In fighting for his succession against Cromwell, the Scots in 1650 enacted that the motto on all their colours and standards should be 'For Covenant, religion, king and kingdom,' and their watchword at the battle of Dunbar was 'The Covenant.' After the Restoration, parliament decreed that the Covenants were not obligatory on the lieges; in 1662 they were declared unlawful oaths, and all acts ratifying and approving them were annulled; in 1682 an oath was imposed specially renouncing the obligations of the Covenants, and in 1685 it was declared to be treason to take them.

During the period, however, between the Restoration and the Revolution, the Covenants were adhered to by many who, upon this account, were called COVENANTERS. They maintained that these Covenants, notwithstanding all acts of parliament to the contrary, were binding upon the nation, and great numbers of them suffered and died in this testimony. Their heroic resistance was justified by the Revolution of 1688, when the nation united in one final effort for the restoration of civil and religious freedom. The Covenants, however, found no place in the polity of the reconstructed Church of Scotland, and so far as it and the nation in general is concerned, they remain a dead letter. They are nevertheless printed along with the authorised standards of the church—viz. the *Westminster Confession of Faith*, and Catechisms, &c. But their continued obligation upon the entire nation remained a prominent principle of the Original Secession and Reformed Presbyterian churches, both of which have frequently renewed them from the Revolution down to the present day. See SCOTLAND (CHURCH OF), CAMERONIANS.

Covenant, in English Law, an agreement by *Deed* (q.v.) in writing, signed, sealed and delivered. A special action of *covenant* lay where a party claimed damages for breach of a covenant; but since the passing of the Judicature Act, 1875, this is no longer a technical expression. A covenant may also be *implied*. 'Covenant running with the land,' is a covenant affecting the land into whose-soever hands it comes. In the United States, the term covenant is used with the same sense as it has in England. The action of covenant is not there in use, a covenant being enforced by an ordinary civil action. The covenant running with the land is almost universally replaced in the United States by a covenant of warranty, by which the grantor of the deed, and not the land itself, is bound.

Covent Garden, corrupted from *Convent Garden*, from having been originally the garden of the Abbot of Westminster, is a spacious square in London, celebrated for a great market held within it of fruit, vegetables, and flowers. The square was formed about 1631 from the designs of Inigo Jones, and has the arcade or piazza on the north and north-east side, Tavistock Row on the south, and the church of St Paul's on the west. In the 17th century Covent Garden was a very fashionable quarter of the town. The scene of one of Dryden's plays is laid here, and frequent allusions are made to the place in plays of Charles II.'s time. The market, now so famous, appears to have originated about 1656 in a few wooden sheds and stalls. Covent Garden is for a stranger one of the sights of London, and is seen to greatest advantage about three o'clock on a summer morning; Tuesday, Thursday, and Saturday being the principal days.

Coventry, a city, parliamentary and municipal borough, and manufacturing town in the north of Warwickshire, on the Sherbourne, an affluent of

the Avon, 18½ miles ESE. of Birmingham, and 94 NW. of London. It stands on a gentle eminence in a valley, with a ridge of hill on the south, and still contains some old houses, with timbered fronts projecting into the streets, and which belong to the 15th and 16th centuries. Town improvements in recent years have necessitated the removal of many old houses and the construction of new streets, the area of the city being greatly extended. The modern buildings include a corn exchange, market-hall, baths, Free Public Library, School of Art, new grammar and other schools, churches, chapels, and hotels, many tricycle and bicycle works, the Coventry and Warwickshire Hospital, and the Coventry Provident Dispensary (about 20,000 members being connected with the last-mentioned institution). Coventry is rich in benevolent and charitable institutions, which have been greatly augmented by the benefactions of the late David Spencer. In 1887 Mr Spencer provided a building for a technical school; a few years earlier he had given four thousand guineas for a public recreation ground; and at his death (June 9, 1888) he bequeathed about £100,000 for benevolent purposes. A beautiful approach to the city from the London and North-western Railway Station has been made by the opening of the Coventry Park for building purposes, and the laying out and ornamentation of Grey Friars' Green. A statue of Sir Thomas White has been erected, and a memorial of James Starley, the inventor of the modern tricycle. At a cost of many thousands of pounds the principal streets have been widened, and a steam tramway now runs through the city. During recent years upwards of £70,000 has been expended in church restoration, and during 1887-89 all of Tennyson's 'three tall spires' were in the restorers' hands. Large sums have also been expended by the various nonconformist congregations in the erection of new, and the restoration of existing places of worship. The chief buildings are the ancient churches, with imposing spires, that of St Michael's rising to a height of 300 feet. St Michael's Church, built 1230-1395, is said to be the largest parish church in England, and is one of the noblest of the lighter Gothic structures. St Mary's Hall, built in the 14th century, for the Guild, is one of the finest specimens of ornamental work in England, with grotesque carved oak roof, ancient tapestry, and great painted window. The ancient walls, three miles in circuit, round Coventry were demolished by Charles II. Coventry returns one member to parliament. The chief manufactures are ribbons, watches, bicycles and tricycles (see CYCLING), cotton, worsted and woollen goods, and art metal works (the Albert Memorial, Hyde Park, London, being of Coventry manufacture). There are large silk-dyeing works. Coventry is nearly in the centre between the four great English ports, London, Bristol, Liverpool, and Hull, and has extensive canal communication with other parts of the country. The city is in an excellent sanitary state, its sewage being treated by an improved system of precipitation, at works erected at Whitley, about one mile from Coventry. The gas and water works both belong to the corporation. Under the Local Government Bill (1888), Coventry is reconstituted a county, and thus reverts to an ancient privilege which it enjoyed from 1451 to 1842. The ancient 'Coventry Great Fair' (formerly eight days) is now held annually, for five days, commencing on Whitmonday. Pop. of parliamentary borough (1841) 30,743; (1861) 41,647; (1881) 46,563, of whom 42,111 were within the municipal borough.

The name Coventry has usually been interpreted 'Convent-town,' but as the form in Domesday is *Coventre*, it is more likely 'town on the Couen'—*Couen* being the ancient British name of the

Sherbourne, and *tree* being 'town.' It is certainly a place of high antiquity. In 1043 Earl Leofric and his wife, Lady Godiva, founded here a magnificent Benedictine monastery. In memory of the noble deed of Godiva (q.v.), curious and splendid processions were formerly held in Coventry. In the 15th century religious mysteries or plays were often acted here by the Grey Friars before kings. Henry VIII. demolished the beautiful cathedral of Coventry. Here occurred the famous meeting for the intended trial by battle between the Dukes of Norfolk and Hereford, immortalised in Shakespeare's *Richard II.* Two memorable parliaments were also held in the monastery of Coventry in the 15th century. The one contained no lawyers, while the other passed attainders against the Duke of York and others. In the 15th, 16th, and 17th centuries, Coventry was famous for woollens, broadcloths, caps, and blue thread bonnets. 'George Eliot' lived in Foleshill Road during 1841-42. See T. Sharp's *History of Coventry* (Birmingham, 1871).

Coventry, SIR JOHN, a staunch cavalier who had sat in the Long Parliament (1640), and who at the coronation of Charles II. was made a Knight of the Bath. Elected for Weymouth in 1667, he asked, during a debate on playhouses (October 1670), a question which reflected on the king's amours. Charles and his minions were furious, and one December night Coventry was pulled from his coach by Sir T. Sandys and other ruffians, and his nose slit to the bone. Parliament took notice of this atrocious outrage, and by its 'Coventry Act' made cutting and maiming a capital offence; but they had not the courage to bring the king's braves to trial. Coventry died in 1682.

Coverdale, MILES, translator of the Bible, was born in Yorkshire in 1488. He made his studies at Cambridge, was admitted priest at Norwich in 1514, when he joined the Austin Friars at Cambridge, and probably imbibed his liking for the new doctrines from Robert Barnes, who became prior about 1523, and whose Protestantism led to his being tried and ultimately burned in 1540. Before long Coverdale went abroad. According to Foxe he was at Hamburg with Tyndale in 1529. His own translation of the Bible appeared in 1535, with a dedication by himself to Henry VIII., and secured the royal license in the quarto and folio editions of 1537. The Psalms of this translation still form the psalter in the Book of Common Prayer, and many of the finest phrases in our authorised version of 1611 are directly due to Coverdale. The original issue of the book is a folio volume, 'faithfully and truly translated out of Douche and Latyn into Englishe,' printed in German black letter, in double columns, with woodcuts and initials, and containing the Apocrypha. Its place of publication is very uncertain, and attempts have even been made to degrade Coverdale from its translator to a mere proof-reader. In the prologue to his own second edition (1550) he states that the translation was his own work, although not at his own cost, and that it was made 'out of five sundry interpreters,' most likely the Vulgate, Luther's version, the Zürich or German-Swiss Bible of 1531, and Tyndale's Pentateuch and New Testament. In 1538 Coverdale was sent by Cromwell to Paris to superintend in Regnault's press another English edition of the Scriptures. Francis I. had granted a license, but in spite of this, before the printing was finished, an edict was issued prohibiting the work. Many of the sheets were burned, but the presses and types were saved and hastily carried over to London, whither also some of the workmen soon came. Grafton and Whitchurch, the noted printers

of that day, were thus enabled to bring out in 1539, under Coverdale's superintendence, the 'Great Bible,' which was presented to Henry VIII. by Cromwell. The second 'Great Bible,' known also as 'Crammer's Bible' (1540), was also edited by Coverdale, who found it expedient to leave England on the fall of his patron Cromwell. While abroad he married, received the degree of D.D. from Tübingen, and acted as Lutheran pastor for some years at Bergzabern, in Rhenish Bavaria. In March 1548 he returned to England, was well received through Crammer's influence, and in 1551 was made Bishop of Exeter, discharging the duties with great diligence and zeal. On the accession of Mary he was deprived of his see, but was suffered to leave the country, at the earnest intercession of the king of Denmark, whose chaplain, Dr Macchabæus (MacAlpine), was Coverdale's brother-in-law. From Denmark he passed to Wesel in Westphalia and to Geneva, where he may have assisted in the preparation of the famous Geneva version (1560), the favourite Bible of the Puritans. Returning to England in 1559, he did not resume his bishopric, but was made D.D. by Cambridge in 1563, and the following year was collated by Grindal to the living of St Magnus, near London Bridge, which he resigned from growing Puritan scruples about the liturgy in 1566. He continued, however, to preach, but died early in 1568, and was buried in St Bartholomew's Church, and on its demolition in 1840 to make room for the New Exchange, was reburied in the south aisle of the church of St Magnus. The tercentenary of his Bible—the first complete English translation of the Scriptures—was celebrated October 4, 1835, when medals were struck in honour of the venerable translator. Most of Coverdale's works, including his letters, were edited for the Parker Society by Rev. George Pearson (2 vols. 1844-46). See *Memorials of Miles Coverdale* (1838), H. R. Tedder's article in the *Dictionary of National Biography* (vol. xii. 1887), and F. Fry's *The Bible by Coverdale* (1867).

Covered-way is a space 11 yards wide in most parts, outside the ditch of a fortress, between the Counterscarp (q.v.) and the Glacis (q.v.). The latter is arranged for musketry in the usual manner, and gives cover to soldiers standing upon the covered-way, which, being also protected from enfilade fire by traverses, is convenient for sentries, and for the passage of troops to the enlarged portions, called *places of arms*, where they assemble for making sorties. See FORTIFICATION.

Covilhão, a town in the Portuguese province of Beira, on an eastern spur of the Estrella Mountains, with some manufactures of brown cloth, and a pop. of 10,986.—Pedro de Covilham (or Covilhão), sent by the king of Portugal in 1486 to visit Prester John's country, reached Calicut overland in 1487, and Abyssinia in 1490.

Covington, a city of Kentucky, U.S., on the Ohio River, opposite Cincinnati, with which it is connected by a fine suspension bridge. Many of the inhabitants transact their business in Cincinnati, but Covington is itself a thriving place, with distilleries, as well as manufactures of glassware, nails, and tobacco. Pop. (1830) 715; (1850) 9408; (1880) 29,720.

Cow. See CATTLE, DAIRY.

Cowbane. See HEMLOCK.

Cowberry. See WHORTLEBERRY.

Cow-bird (*Molothrus peccoris*), also called Cowpen Bird, Cow Blackbird, &c., a native of North America, nearly allied to the Troupials, remarkable for its cuckoo-like habit of utilising the nests of other birds for its own eggs. The latter are

hatched sooner than those of the rightful owners, which fall victim to this lofty form of parasitism. The cow-bird is about 7 inches in length, predominantly brownish-black in colour, and has a short but sharply pointed beak. 'It utters a peculiarly liquid April sound.' The females are far more numerous than the males, and polygamy is therefore in vogue. The males have deeper, glossier coats than the females. It is said to damage the fields of sown maize, but feeds largely on insects. The name refers to its habit of frequenting cow-pens for the sake of the attracted insects. Seven other species of *Molothrus* are known, occurring from La Plata to the United States.

Cow-boy. See RANCHING.

Cowbridge, a municipal borough of Glamorganshire, on the Ddaw, 12 miles W. of Cardiff (17 by rail), with which and Llantrissant it returns one member to parliament. It has an old gateway and a grammar-school (1678). Pop. 1229.

Cow-catcher, a kind of barred iron cone or hook shaped arrangement, about 6 feet long, projecting from the front of locomotives, close over the railway track, and attached to the buffer-beam by strong bolts. It is generally used upon American lines where unfenced. Sometimes it is sheathed with iron plates in winter, when it acts as a snow-plough. Despite its name, it catches no cows, but generally throws any animal struck up on the buffer-beam, or clears the line by shoving forward and tossing aside.

Cowdenknowes. See EARLSTON.

Cowell, EDWARD BYLES, a learned Sanskrit scholar, was born at Ipswich, January 23, 1826. He was educated at Ipswich grammar-school and Magdalen Hall, Oxford, and in 1856 sailed for Calcutta, to fill the chair of History in the newly-established Presidency College, becoming also soon after principal of the Sanskrit College. He returned home in 1864, and was elected in 1867 professor of Sanskrit at Cambridge, and in 1874 to a fellowship in Corpus Christi College. His most important works are Vararuci's *Prākṛta-Prakāśa*, text and translation (1854); *Kātha-Upanishad*, text and translation (Calcutta, 1861); editions of a part of the *Yajurveda*, with Dr Roer (1858-64), of the *Maitri-Upanishad* (1864), and the *Kusumāñjali* (1864); and translations of the *Cāṇḍīya-Sūtras* (1878) and the *Sarvadurgā-Saṃgraha*, with Gough (1882). In 1873 he edited Colebrooke's *Essays*. A later work is the *Dīrghavadāna*, a Sanskrit collection of Buddhist legends, edited with P. A. Neil (Cambridge, 1886).

Cowen, FREDERIC HYMEN, composer, born at Kingston, Jamaica, 29th January 1852, studied under Benedict and Goss, and in Germany, and in 1868 settled in London. He has produced an opera, *Pauline* (1876), four cantatas, several symphonies, one of which, No. 3 (Scandinavian), is esteemed throughout Europe, a number of overtures, piano-forte pieces, and minor works, and over 100 songs, many of them very popular.

Cowes, a seaport and watering-place in the north corner of the Isle of Wight, 1½ miles SSE. of Southampton by water, and 4 N. of Newport by rail. It consists of West and East Cowes, lying on opposite sides of the mouth of the estuary of the Medina, and connected by steam-ferry. Standing on a hill-slope, West Cowes has a striking aspect from the sea, and is the seat of much trade, being the chief port of the island, and the headquarters of the Royal Yacht Club (1815), whose regattas are held here. Their club-house was originally a fort, built by Henry VIII. in 1540. Yacht-building is the great speciality of Cowes, which has a fine promenade (1864), excellent hotels, baths, villas,

lodging-houses, &c. Slatwoods at East Cowes was the birthplace of Dr Arnold, and in the vicinity are East Cowes Castle (1798), Norris Castle (1799), and Osborne House (1845). The last, built by Cubitt as a marine residence for Queen Victoria, is an Italian edifice, with a flag-tower 112 feet high, and beautiful grounds. Pop. of West Cowes (1851) 4786, (1881) 6772; of East Cowes (1861) 1954, (1881) 2615.

Cowhage, COWAGE, or COWITCH, consists of short, slender, brittle hairs, which cover the pods of species of *Mucuna*, a papilionaceous climber, particularly *M. pruriens* of the West Indies and *M. urens* of the East. These hairs readily stick in the skin and cause intolerable itching, and were hence formerly used (as still in their native country) as a vermifuge. They are administered in syrup, and of course act mechanically. The unripe pods are eaten like kidney-beans.

Cowl. See BENEDICTINES.

Cowley, ABRAHAM, in his own day considered the greatest of English poets, was born in London, 1618. His father was a stationer in that city, and died before his son's birth. By the exertions of his mother, Cowley received a learned education. At an early age he was sent to Westminster School, where he displayed an almost unparalleled precocity. It was by the reading of the *Fairy Queen*, a copy of which lay in his mother's window, that his mind was turned to poetry. He wrote excellent verses at the age of ten, and published a volume of poems at fifteen. In 1637 he proceeded to Cambridge, and while here wrote, among many other pieces, a large portion of his epic, the *Davideis*, on the subject of the life of King David. On the outbreak of the Civil War, he was ejected (1643) from Cambridge for refusing to take the oath tendered to all the members of the university. At Oxford, however, the headquarters of the king's party, he continued his studies for other two years. On the queen's flight to Paris, Cowley followed her, and did effectual service to the royalist cause by various missions, and by carrying on the secret correspondence in cipher between the queen and Charles. In 1656 he returned to England, but was arrested and only allowed at large on a bail of £1000. To conciliate the party in power, he qualified himself as a doctor of medicine, by way of proving that he had abandoned all political connections. On Cromwell's death, Cowley again went to Paris, but returned to England at the Restoration. He was disappointed in the hope of preferment, especially of the mastership of the Savoy, which both Charles and his father had led him to expect. By the generosity of the Duke of Buckingham and Cowley's lifelong friend the Earl of St Albans, he at length received a comfortable provision. Cowley died at Chertsey, London, 28th July 1667.

Cowley's most ambitious works are the *Davideis*, the *Pindarique Odes*, written in supposed imitation of Pindar, and the *Mistress*, a series of love poems. His fate as a poet is one of the most singular in literature. Deemed unapproachable in his own day, he has ever since sunk steadily in popular estimation. Dr Johnson's explanation is still accepted as the best that can be suggested. Cowley wrote for the court and the reigning taste, and not for the general heart of men. What he is still admired for is his astonishing ingenuity and agility of mind. Moreover, though the bulk of his verse can never again have any living interest, he has not a few passages characterised by delicacy and power. By his small collection of essays, Cowley takes rank with Goldsmith and Addison as one of the masters of simple and graceful prose style. It is by these essays that Cowley is now best known to modern readers. They are included in Grosart's

complete edition (1881). See Sprat's *Life of Cowley* (1668), and Johnson's *Lives of the Poets*.

Cowley, HANNAH (1743-1809), wrote thirteen lively dramatic works, including *The Belle's Stratagem* (1782), and several volumes of feeble verse. She was attacked along with the other Della Crusceans by Gifford in the *Baviad* and *Maviad*.

Cowley, HENRY RICHARD CHARLES WELLESLEY, EARL, diplomatist, was born June 17, 1804. His father, the first Baron Cowley, was a younger brother of the great Duke of Wellington. He was educated at Eton, and at twenty began a long career as a diplomatist by becoming an attaché at Vienna. He was in succession secretary and ambassador at Constantinople, minister-plenipotentiary to Switzerland (1848), to the Germanic Confederation (1851), and in 1852 succeeded the Marquis of Normanby as ambassador at Paris, a position which he held with rare tact and temper throughout all the difficulties that occurred until his resignation in 1867. With Clarendon he represented Great Britain at the Paris Congress of 1856, and in 1860, with Cobden, he arranged the commercial treaty between France and England. He succeeded to his father's title in 1847, was created Viscount Dangan and Earl Cowley in 1857, and made a K.G. in 1866. He died July 14, 1884.

Cow-parsnip (*Heracleum*), a genus of Umbelliferae, of which one species (*H. Sphondylium*) is a common and rank wayside weed, which, however, when cut early in the season, affords a wholesome fodder to pigs and cattle. *H. sibiricum*, a much larger species, has been recommended for cultivation on account of the great quantity of herbage it yields very early in the season, and with other species (*H. giganteum*, &c.) it is also used with much effect as a decorative plant. *H. lanatum* is very common in North America.

Cowper, WILLIAM, surgeon and anatomist, was born at Petersfield, in Sussex, in 1666, settled as a surgeon in London, and died 8th March 1709. He made some new anatomical observations, notably discovering the glands beneath the male urethra called 'Cowper's glands,' and published *The Anatomy of Human Bodies* (1698) and other works.

Cowper, WILLIAM, was born in 1731 at the rectory of Great Berkhamstead, in the county of Hertford. He was sent to Westminster School at so early an age that all his impressions were painful, and he thus conceived a hatred of public schools which was never modified. He complains that there he became an adept 'in the infernal art of lying,' an art which we could hardly assert either to be extinct in our public schools at the present time, or to be or ever to have been entirely confined to them. Among his schoolfellows were Churchill the poet, and Warren Hastings; and for these two at least he seems to have maintained a lasting affection. On leaving school he was articled to an attorney named Chapman, with whom he idled away his time for several years. One of his fellow-pupils there was Thurlow, who in a jesting mood promised to give Cowper an appointment when he should be Lord Chancellor. The boyish ambition was verified, as every one knows, but not the promise. Cowper was called to the bar in 1754, and lived for some time the ordinary life of a young man, not uncheerful, though with occasional fits of depression. He belonged to the 'Nonsense Club,' founded by Bonnell Thornton and George Colman, and is supposed to have contributed some short articles to the *Connoisseur*, a paper started by them. He also fell in love, during this period, with Theodora, the daughter of his uncle Ashley Cowper, a lady who seems to have had for him a far deeper feeling

than his essentially recipient nature could return. Certainly he appears to have made no particular effort to overcome his uncle's opposition to his suit. In those days a well-connected young man was more easily provided for than now, and a sinecure appointment, as 'Commissioner of Bankrupts,' gave Cowper a certain independence, which he enjoyed tranquilly, relying on the influence of his relations to promote him further, an expectation which they on their side did all they could to fulfil. His cousin, Major Cowper, had the right (extraordinary to hear of nowadays) of appointing to the office of Clerk to the Journals of the House of Lords, and also to the joint offices of 'reading clerk and clerk of the committees' to the same august assembly. All these appointments happened to fall vacant at the same time (1763). Major Cowper wished his cousin to take the latter and more valuable office, but Cowper in one of his fits of self-depreciation, preferred the other, which was found eventually to involve a so-called examination as to his fitness for the office, meaning in fact only an appearance before the bar of the House. The idea of this appearance unmanned him altogether. A fixed idea, the well-known forerunner of madness, that every one was hostile to him, gradually took possession of his mind; and the horror grew by continual brooding, until suicide seemed the only way of escape. He several times attempted to make away with himself, and on one occasion at least was only saved by a fortunate accident. When his friends were finally made aware of his condition, they gave up at once a project so evidently impracticable; but Cowper's mind was permanently unhinged. He fell into a state of religious despair as to the consequences of the crime he had almost committed, in the height of which his misery found vent in the composition of a copy of *Sapphics*, in which he describes himself as 'damned below Judas, more abhorred than he was,' and again, 'man disavows and Deity disowns me.'

It was found necessary to remove him to a private asylum at St Albans, where he was gradually restored to health by judicious treatment. After this, in June 1765, he drifted to the quiet town of Huntingdon, where he made acquaintance with an amiable and religious family to which he was at once attracted, and in which he was soon accepted as an inmate. The head of the family, Mr Morley Unwin, was a clergyman, but retired from active work, and with his wife and two children lived a life of almost perpetual devotion, into which Cowper plunged, spending most of his time in religious exercises of various kinds, and correspondence on religious subjects. Cowper continued to reside with Mrs Unwin after her husband's death (July 1767), but they soon removed to Olney in Buckinghamshire, where the famous John Newton was curate. This remarkable man soon acquired the most complete influence over the gentle invalid; and, under Newton, Cowper worked among the poor of his friend's parish, devoting his whole time to pious exercises and good works. Owing, perhaps, to these exertions, and to the unbroken monotony of the atmosphere, signs of his former madness began to reappear, and in 1773 it burst out. He was at the time in Newton's vicarage, and here he remained for more than a year, refusing to return to his own house though it was but next door. After his recovery (which was never complete) he lost—we might almost say, though it seems cruel, he was delivered from—the companionship of Newton, who was presented in 1779 to the rectory of St Mary Woolnoth. The effect of his departure on Cowper was miraculous; whether Newton, in his intense enthusiasm miscalculated his friend's powers, or whether he was only ignorant

of the delicate nature of the mind on which he was working, it is evident that the constant intercourse with him, aided perhaps by the wearying sameness of the life, had an oppressive and crushing effect upon Cowper. Even after Newton's departure, the old gloom appears in letters addressed to him, while in correspondence with Hill or Unwin, Cowper is always cheerful, full of graceful playfulness, entering into a pleasant record of his amusements and occupations, his hares and garden and greenhouse. To the quiet of this period of his life we probably owe the tranquillised condition of mind which makes the tone of Cowper's poetry contrast so strangely with the sentiments of his early experiences. An astonishment almost amounting to incredulity fills our mind when we find the madman, the religious fanatic, who despaired of salvation, and on several occasions attempted suicide, luxuriating in the quiet of nature, which he fully appreciated and enjoyed, and changing his abject fears of God's wrath for a tender delight in and love of the ordinary works of His hands.

He was, however, as yet no poet at all. Mrs Unwin was the first who had the wisdom to perceive that a variety of occupation was necessary to Cowper, and that something to occupy his mind during the gloomy months of winter was of the highest importance to his well-being. No power of initiation seems to have existed in his mind, but he followed with docility his friend's suggestions, and when she bade him write poetry, did so. His first volume (1782) was in the fashion of the time, and consisted of several poems on abstract subjects, a poetical dialogue called 'Table Talk' being added to lighten and enliven the book. Probably Cowper himself was not conscious at the time how much higher he was capable of flying and was destined to fly; but once more a happy suggestion came to his aid. In 1781 he accidentally made the acquaintance of Lady Austen, a woman full of intelligence, and of a gay and happy disposition, bringing sunshine with her. The acquaintance rapidly grew into a warm friendship, and Lady Austen settled in Newton's deserted vicarage, next door, it will be remembered, to Cowper's house. The inhabitants of the two houses soon, of course, grew intimate, with the happiest results to the poet. It is to Lady Austen's playful commands to write a poem for her on any subject, 'this sofa for instance,' that we owe Cowper's greatest work, *The Task*. She has also the credit of having told him the story of John Gilpin, reproduced in the immortal ballad the next morning: and there can be no doubt that this lady was his better angel, and made the happiest revolution in the too-serious house. His position between his old friend and his new one, both being women, has been the subject of many, and we think somewhat vulgar comments. That Cowper was engaged to marry Mrs Unwin, that this project was defeated by a dawning love between the poet and Lady Austen, and that jealousy and passion came in to disturb their relations is an oft-repeated tale. It surely, however, requires but little reflection to see how unnecessary such a theory is. Cowper was in every way calculated to arouse a more than passing interest in the heart of an intellectual woman, but neither in his past nor his present was there anything that could inspire such a woman with the desire of marrying him. He had the gift of making friends and calling forth sympathy in an unusual degree, and the influence of this tender sympathy not only saved but made him what he grew to be. If Lady Austen had never said to Cowper, 'Why not try blank verse?' that grand revolt against the smoothness and artificial perfection which Pope had established as essentials of poetry might have been indefinitely postponed. Against a style which repelled him,

Cowper was the first to protest by the effectual reproduction of a more excellent way. He took that polished and splendid instrument from the hand of Milton, without his grandeur of tone, yet with a sweetness and serious power not unworthy of it. His schoolfellow, Churchill, had struck a rougher and more vigorous note, yet had not been bold enough to return to the old ways. But the timid poet in his seclusion, under the influence of his domestic muses, with unexpected boldness, seized on his inheritance. Wordsworth carried on both style and subjects, but he, like Gray, put of his own into the theme, and described less Nature herself than the thoughts which she inspired. In Cowper, on the contrary, we have Nature's very face, the calm description of a quiet scene painted by one who loved her for herself, not peopled with fancies by a poetical observer.

How his friendship with Lady Austen came to an end has never been clearly known, but at the end of 1783 she retired to Bristol, and Cowper writing to Unwin declared the connection at an end. It is a commonplace to talk, of course, of jealousy between Lady Austen and Mrs Unwin, and it is easily comprehensible that the latter lady may have objected to see her place as Cowper's friend and adviser taken from her by a stranger. However, as regards our poet, Lady Austen had done her work; *The Task* was published in 1785, and its power and the greatness of the old-new method very soon made themselves apparent. Whether Cowper has retained the high place which was accorded to him in the surprise and delight of the new movement, is a question which will be answered according to individual tastes and opinions, but there can be no doubt that the publication of *The Task* had a most powerful effect upon the literary tastes of the time.

It is characteristic of Cowper that on the departure of Lady Austen, he fell for some time into a little of his old melancholy, until in 1786 Lady Hesketh appeared upon the scene, and the poet accepted the new comforter in lieu of her who was gone. His translation of Homer was carried on under the influence of this new adviser, who was a relation of his own, and consequently escaped the imputation of wishing to marry him. She procured the removal of the sad poet and his ailing companion to Weston-Underwood, where they made acquaintance with the Throckmorton family, and received much comfort and consolation in their waning days. This move, as well as the translation of Homer, Newton, with whom Cowper still kept up a correspondence, condemned with almost brutal violence of language, and it is an evidence of his temporary recovery of strength, that Cowper defended himself without, however, losing his temper. Against Newton's advice he continued his translation, which brought him in at least a little money if not much fame: and the money was by this time much needed. In 1787 he had another attack of his old ailment, and again attempted suicide. From this attack he never seems to have completely recovered, and when he was almost at his worst, Mrs Unwin had a stroke of paralysis which cast a gloom over this devoted pair from which they never emerged. In 1794 a pension of £300 a year was assigned to him, but too late to confer much comfort or relief. When Mrs Unwin died in 1796 he heard the news without emotion, and growing gradually weaker, died peacefully at East Dereham, Norfolk, on the 25th of April 1800. Curiously enough, out of the gloom of his last waning years came two of his most beautiful and touching poems, the lines 'Addressed to My Mother's Picture,' and those entitled 'My Mary.'

Hayley's Life first appeared in two volumes in 1803. The later editions (1806, 1809, 1812) were in four volumes,

and contained supplementary letters. The standard edition of Cowper's works is that edited by Southey, with a memoir (15 vols. 1834-37), and reprinted in Bohn's 'Standard Library' (1853-54). Others are those of Grimshawe (8 vols. 1835), the Aldine edition, with a good life by John Bruce (1865), and the Globe edition, with a memoir by Rev. W. Benham (1870). There are selections of the poems, by Mrs Oliphant (1883), and of the letters, by Rev. W. Benham (1884) in the 'Golden Treasury' series. For criticism, see Ste. Beuve's *Causeries du Lundi* (vol. xi. 1868); Stopford-Brooke's *Theology in the English Poets* (1874); Goldwin Smith's monograph in the 'English Men of Letters' series (1880); Leslie Stephen, in series iii. of 'Hours in a Library' (1882); and Mrs Oliphant, in *The Literary History of England* (1882).

Cow-plant (*Gymnema lactiferum*), a perennial Asclepiad of Ceylon, which has acquired a factitious celebrity from the oft-repeated statement that its milky juice is used as milk, and that its leaves are boiled to supply the want of cream! But this, according to Sir J. E. Tennent, arises entirely from the appearance of the juice, which indeed probably contains a share of the poisonous principles so general in this order.

Cowry (*Cypræa*), a large genus of Gasteropods in the Prosobranchiate section, including over a hundred species, some of which are very familiar as decorative objects and as furnishing a medium of exchange with uncivilised peoples. The shell has more or less of an oval form, and is usually thick, polished, and beautifully coloured. The young shells are delicate and more typically snail-like, but in the adults the large last whorl more or less conceals the others, and has its outer lip bent in towards the inner. The internal axis may be wholly absorbed. The animal has a broad head, a protrusible proboscis, eyes associated with the long horns, and a broad foot protruded through the elongated aperture. The mantle or skin fold, which forms the shell as in other molluscs, extends over the whole or most of the surface, and thus conceals during life what gives the dead shells half their charm. In habit the cowries are predominantly sluggish animals, creeping slowly on rocks and coral reefs. They are mainly carnivorous in diet. Though widely distributed, they thrive best in the tropical seas. Fossil forms occur abundantly (about 80 species) from the chalk onwards. The nearest relations of the cowries are the two genera *Ovulum* and *Trivia*. The former includes the *Poached Eggs* and the *Waver's Shuttle* (*Ovulum volva*); two species are found on British shores. The genus *Trivia* includes the little 'cowry' (*Trivia europæa*), not uncommonly found on British coasts—e.g. near John o' Groat's House.

The cowries proper are well known in several practical connections. The money cowry (*C.*

moneta), common in the Indian and Pacific oceans, is used as currency in many parts of Southern Asia and Africa. In India its value has varied between 2400 and 3200 to the rupee.

Cowries are familiar in England as counters in games

of chance. From prehistoric times they have been used to form necklaces and other ornaments of the person. In some cases they are worn as charms, and their bright colours, so attractive to human eyes, have also been utilised in catching cuttle-fishes. Cowries have had their share in later days in the conchological craze, and 'small fortunes' have been spent in gathering that wealth of varied colour which a good cabinet dis-

plays. A single shell of *C. princeps* has been sold for £40.

Cowslip (*Primula veris*; see PRIMROSE),* a common native of pastures in England and many other parts of Europe, although rare in Scotland, a delicate and modest little flower, a universal favourite, both for its beauty and its fragrance. It differs from the common primrose conspicuously in having umbels of flowers on a scape; it is supposed to be the original of the garden polyanthus. Darwin holds the common cowslip to be a cross between the cowslip and the common primrose. Its bells were long supposed to be the haunt of fairies, and the name of Fairy Cups is still given to them in some parts of England. The flowers are sometimes fermented with sugar to make *cowslip wine*, which is not unpalatable. It was once a favourite domestic soporific. The leaves are by some used as a salad and pot-herb, and also as food for the silkworm before those of the mulberry have expanded. The American cowslip (sometimes also called Shooting-star) is *Dodecatheon Meadia*, a very handsome spring flower. This and other species are also well known in cultivation.

Cow-tree, a name given to a number of trees of different natural orders, the bland milky juice (Latex, q.v.) of which is used instead of milk. The most famous of these is the Palo de Vaca of the Cordilleras and Caraccas (*Galactodendron* (*Brosimum*) *utile*), an artocarpaceous tree, with large laurel-like leaves and very small flowers. The milk is obtained by piercing the bark of the trunk or branches, and flows so freely that an ordinary bottle may be filled in half an hour. The milk has an agreeable creamy odour and taste recalling that of cow's milk, but is slightly viscid and soon becomes yellow, gradually thickening into a somewhat cheesy consistency. Its chemical composition, of course, widely differs from that of milk, but its nutritive value is considerable. It is much used by the negroes and Indians.

The cow-tree or Hya-hya of Demerara is *Tabernaemontana utilis*, a tree belonging to the Asclepiadaceæ. In this order the milky juice is usually acrid and poisonous, and even that of other species of the same genus is of sharp and burning taste. In this case, however, the latex is agreeable and wholesome, although somewhat sticky, owing to the large proportion of caoutchouc.

Cow-wheat (*Melampyrum*), a genus of Scrophulariaceæ, of which the deep-furrowed two-celled capsule somewhat resembles a grain of wheat. They are annual weeds, growing in woods, corn-fields, and pastures, and are eaten by cattle. Being root-parasites, they grow on the roots of other plants. *M. pratense* is common in Europe and North America.

Cox, DAVID, landscape-painter, was born at Deritend, a suburb of Birmingham, 29th April 1793. His father was a blacksmith, and he worked at the forge for a time; and after trying various employments and studying drawing under Joseph Barber, he was scene-painter in the Birmingham, Swansea, and Wolverhampton theatres, and occasionally appeared upon the boards in minor parts. He next took lessons in London from John Varley; in 1805 and 1806 visited North Wales, which to the end of his life was his favourite sketching-ground; and taught as a drawing-master, mainly in Hereford, publishing *A Treatise on Landscape Painting and Effect in Water-colours* (1814), and other educational works, illustrated by soft-ground etchings by his own hand. In 1813 he joined the Society of Painters in Water-colours, to whose exhibitions he was a regular contributor. From 1827 till 1841 his headquarters were in London, but he was constantly sketching in the country,

Money Cowry.

and occasionally he made brief visits to the Continent, executing water-colours of noble quality which slowly but steadily made their way with the public, and are now recognised as entitling their painter to a place among the very first of English landscapists. In 1839 he turned his attention seriously to oil-painting, a medium which he had hitherto used only for sketching, and soon he had mastered the process. He executed in all about a hundred works in oil. These are less widely known than his water-colours, but they are of at least equal quality. In 1841 he settled at Harborne, near Birmingham, where he resided for the rest of his life. It was during this period that he produced his greatest works, those most rapidly synthetic in execution, and most deeply poetic in feeling. They mainly owe their inspiration to the scenery of North Wales, and especially of Bettws-y-Coed (q.v.), which he visited every autumn. He died at Harborne, 15th June 1859. The manliness and simplicity of the painter's own character is reflected in his direct, faithful, and forcible art. His works are distinguished by great breadth, purity of tint, truth of tone, and brilliancy of effect, and they are admirable in their rendering of atmosphere, and in their suggestion of the sparkle and breezy motion of nature. Among the more celebrated of his oil pictures are 'Lancaster Castle' (1846); 'Peace and War' (1846), a small picture 18½ by 24 in., for which Cox received £20, but which fetched £3602 in 1872 (his lifelong ambition had been 'some day, D.V., to get £100 for a picture); 'The Vale of Clwyd' (1846 and 1848); 'The Skylark' (1849); 'Boys Fishing' (1849); and 'The Church of Bettws-y-Coed.' Among his very numerous water-colours are 'Lancaster Sands' (1835); 'Ulverston Sands' (1835); 'Bolton Abbey' (1847); 'Welsh Funeral' (1850); and 'Broom Gatherers on Chat Moss' (1854). His water-colour titled 'The Hayfield,' fetched £2950 in 1875. His works have been frequently brought together in exhibitions, and he was admirably represented by forty-six examples in the Manchester Exhibition, 1887. See the Memoir by N. N. Solly (1875), and the Biography by William Hall (1881).—His son, David Cox the younger (1809-85), was also known as a water-colour painter.

Cox, Sir George, an eminent mythologist, was born in 1827, and educated at Rugby and Trinity College, Oxford. He took orders in 1850, and after holding curacies in Devonshire, and an assistant-mastership at Cheltenham, became vicar of Bekesbourne in Kent, and afterwards rector of Scrayingham, York. In 1877 he succeeded to his uncle's baronetcy. An industrious man of letters, he has written much on ancient history and on mythology. His *Tales of Ancient Greece* (1868) was a collected edition of several admirable earlier volumes of Greek history. His most important work, *The Mythology of the Aryan Nations* (2 vols. 1870), was an uncompromising development of the solar and nebular hypothesis as the key to all mythologies. It is learned, lucid, and courageous; but the extreme to which a serviceable enough theory has been pushed in an attempt to account for the unaccountable, and to reconcile the irreconcilable, has exposed its real weakness. His *History of Greece* (2 vols. 1874) was a work of great learning, and his *Introduction to the Science of Comparative Mythology and Folklore* (1881) showed its author's old ingenuity and erudition, but none the less the singular limitation of his knowledge. Other works are *Latin and Teutonic Christianity* (1870), *The Crusades* (1874), *History of British Rule in India* (1881), and *Lives of Greek Statesmen* (2 vols. 1886), and concise *History of England* (1887). With W. T. Brande he edited the useful *Dictionary of Science, Literature, and*

Art (3 vols. 1865-67). His *Life of Bishop Colenso* appeared in 1888.

Coxe, Henry Octavius, librarian, was born at Bucklebury vicarage in Berkshire, September 20, 1811. He had his education at Westminster and Worcester College, Oxford, and entered the manuscript department of the British Museum in 1833, soon after taking orders. In 1838 he became attached to the Bodleian Library, in 1860 its head, and here his marvellous knowledge and patient kindness made him the very ideal of the librarian. Already in 1857 he had been sent by Sir G. C. Lewis to the East on a tour of discovery, which resulted indeed in his finding many codices, though the grasping greed of the ignorant monks, at last awakened to their value, made it impossible to buy them. Coxe held in succession several curacies near Oxford, and in 1868 became rector of Wytham. He was Select preacher in 1842, Whitehall preacher in 1868, and in 1878 presided at the first annual meeting of the Library Association at Oxford. Coxe died July 8, 1881. Although himself an excellent palæographer and ripe scholar, Coxe did much more for others' reputations than his own. The most important of his own works were an edition of Roger of Wendover's *Chronicle* (5 vols. 1841-44), and of Gower's *Vox Clamantis* for the Roxburghe Club (1850), and his Catalogues of MSS. in the colleges and halls of Oxford (1852), and of the Bodleian MSS. (1853-54). See Dean Burgon's *Lives of Twelve Good Men* (1888).

Coxe, William, historical writer, was born in London, 7th March 1747, and from Eton passed to King's College, Cambridge, of which he became a fellow in 1768. As tutor to the sons of four persons of quality, he spent much of twenty years on the Continent, where he neglected no opportunity of collecting information about the countries which he visited. The result appeared in fourteen works of travel and history, careful but dull, the best known being his *History of the House of Austria* (1807). He died, a prebendary of Salisbury and Archdeacon of Wilts, at Bemerton rectory, 16th June 1828.

Coxswain, or **COCKSWAIN** (pronounced *corn*, and often abbreviated to *cox*), on board ship, is the steersman of a boat, and commander of the boat's crew. In boat-racing, the coxswain should always by preference be a very light weight. See **ROWING**.

Coxwell, Henry Tracey, aeronaut, born in 1819, at Wouldham, near Rochester, was educated for the army, but settled as a surgeon-dentist in London. From boyhood he had taken a keen interest in ballooning; in 1844 he became a professional aeronaut, and in 1845 established the *Aërostatic Magazine*. Since then he has made some 700 ascents, the most remarkable being that of 1862, when he reached, with Mr Glaisher, a height of seven miles. He is author of *My Life and Ballooning Adventures* (2 vols. 1887-88). See **BALLOON**.

Coyote. See **WOLF**.

Coypu (*Myopotamus coypu*), a large rodent in the porcupine section of the order. It is the only known species of its genus, is common in South America on both sides of the Andes, lives (in pairs) in burrows near water, and feeds on aquatic plants. The animal measures from one to two feet in length, not including the long scaly tail; the general colour is brown varying towards yellow; the hind-feet are webbed and enable the coypus to swim well. The mother-animal swims with her young on her back, and this habit may have something to do, it is suggested, with the peculiar position of the teats, which are high up on the

flanks. The coypu is much hunted for its flesh and fur. The latter is best known under the

Coypu (*Myopotamus coypu*).

Spanish name of Nutria, and forms an important article of commerce.

Cozens, JOHN ROBERT, water-colour painter, was born in England in 1752. He was instructed by his father, Alexander Cozens, also known as an artist in water-colours, who was one of the two natural sons of Peter the Great, by a woman from Deptford who accompanied the Czar to Russia. In 1776 he visited Switzerland, with R. Payne Knight, and in 1783 returned from an extended tour in Italy with William Beckford, who commissioned many of the washed drawings which he then executed. Among his English subjects are some fine studies of trees made in Windsor Forest. In 1794 the artist's mind gave way, and in his later days he was befriended by Sir George Beaumont and Dr Munro. The date of his death has been usually stated as 1799, but there is reason to believe that he was alive after 1801. The great qualities of his art have commanded the enthusiasm of brother-painters. Turner and Girtin copied his drawings, and Constable pronounced that 'his works were all poetry,' that he was 'the greatest genius that ever touched landscape.' He to some extent extended the very limited colour-scheme of previous painters in the medium, introducing greater force and variety of tinting; and he substituted for their topographical treatment of landscape a rendering more imaginative and more perceptive of the delicacies of atmospheric effect. In composition, his works are singularly large and harmonious, and they evince an especial sympathy for nature in her moods of placid sublimity. There is a fine series of his works in the British Museum Print Room.

Crab, a popular name legitimately applied to any of the short-tailed (*Brachyura*) division of decapod Crustaceans (q.v.). The body is usually short and compressed; the abdomen is short and is tucked up beneath the relatively large cephalothorax; there are 1 to 4 reduced abdominal appendages, but seldom any tail-paddles; the antennæ are short. In the common Shore-crab (*Carcinus menas*) the carapace is a wide shield, broader than long, and bent inwards at the sides; the eyes are stalked, and lie as usual above and in front of the antennules, though apparently rather external to them; the antennules have the ear-sac lodged in their dilated base; the bases of the antennæ are immovable, and the opening of the excretory organ at their base has a curious movable plate. The hindmost of the foot-jaws or maxillipedes is in part expanded into a broad plate which covers the neighbouring appendages. The great claws are generally larger in the male than in the female, and thus the market value of the male Edible Crab (*Cancer pagurus*) is said to be five times as great as that of the female. The reduced

abdominal appendages of crabs are solely used for reproductive purposes. The two anterior pairs are copulatory in the males; those that persist in the females have the eggs attached to them. The abdomen is always larger and broader in the females. The nervous system is peculiar in the centralisation of the thoracic ganglia into a single mass. The alimentary, circulatory, and excretory systems do not present any important peculiarities. The gills are always fewer than in the crayfish, never exceeding nine on each side. The gill-cavity is large, especially in the land-crabs. In the common shore-crab, the larva leaves the egg as a zoea, after repeated moults becomes a sort of hermit-crab-like form known as a Megalopa, and gradually with broadening shield, loss of abdominal

Great Crab (*Cancer pagurus*).

appendages, bending up of the abdomen, and modification of the anterior limbs becomes a miniature adult.

General Life.—Crabs feed chiefly on other animals both alive and dead. The Swimming Crabs (*Portunus*)—e.g. *P. pelagicus*, attack fishes. *Cardisoma carnifex*, found in the mangrove swamps of the West Indies, is fond of the fruit of a species of Anona, but is also notorious for burrowing in the cemeteries. The well-known Land-crab (*Gecarcinus ruricola*) damages sugar-canes. Many crabs are very rapid runners, especially the sand and land forms; others are powerful burrowers—e.g. the Calling Crab (*Gelasimus*), which has one of its great claws much exaggerated, and carried during locomotion over its head in such a way that it looks as if it were beckoning; others again are expert swimmers—e.g. our British pelagic *Polydora henstovii*, which has a light shell, and four of its thoracic appendages flattened for swimming. In regard to respiration it is worth noticing that the land-crabs are so far terrestrial that they are liable to be drowned in water. The male crabs are usually larger, and sometimes fight with one another as well as with other species. In some cases (*Gelasimus*) the bright colour is only acquired at the period of reproductive maturity. The sexes of the common Shore-crab (*Carcinus menas*) are said to unite just after the female has moulted her hard shell. In all but the land-crabs the female carries about the eggs till they are hatched.

Habitat.—Almost all crabs are strictly marine forms, and the majority frequent shallow water. Among the terrestrial forms the best known are the species of *Gecarcinus*, swiftly moving nocturnal crabs in tropical regions of both hemispheres, chiefly vegetarian in their diet, migrating in companies to the sea for egg-laying purposes. The genus *Ocypoda* includes some land forms, and some which produce a shrill noise by rubbing the ridged surface of the second-last joint of

the right great claw against a sharp edge of the second joint. The Calling Crab (*Gelasimus*) makes large burrows, and the male closes the mouth of the hole with its exaggerated great claw. The Pea-crabs (*Pinnotheres*) live inside bivalves (*Pinna*, *Mytilus*, *Macra*, &c.). One species (*P. veterum*) was said by the ancients to nip the mollusc when danger threatened, and to receive its share of food in return. There is no doubt as to the share of food, but no evidence that the crab rewards its host. In the genus *Telphusa* all the species live in fresh water in the warm parts of the globe. The European species (*T. fluviatilis*) is tolerably common in southern Europe, was known to the ancients both in its habit and edibility, and is often figured on Sicilian coins. As regards geological distribution, the *Brachyura* do not certainly appear before the upper Jurassic, and become gradually more numerous in Cretaceous and Tertiary strata.

Moulting and Amputation.—Like other crustaceans, crabs periodically cast their chitinous and limy shells. The moults are most frequent in youth, when the rapid growth of the body conflicts with the rigidity of the armature. Extra feeding may accelerate the process. Before moulting the old shell becomes virtually dead, reserve stores are used in fresh growth, a new shell begins to form within the old, and finally with considerable, and sometimes fatal effort, the shell is cast. It is left in apparent intactness, a very image of its lost tenant. The new suit, which is at first soft, requires several hours or days to acquire firmness. The loss of internal linings, of stomach mill, of the outer covering of the eyes, &c., as well as of the entire outer armature, leaves the crab very much *hors de combat*. The period is one of great disadvantage to the crabs, not only from the fatigue and often fatality of the process, but from the state of defenceless helplessness in which they are temporarily left. In many cases crabs lose their limbs in fighting, and they may voluntarily resign them (as in *Porcellana plutechelys*) to save their bodies. Sudden panic or injury is said to lead to similar self-inflicted amputation or 'autotomy.' Like many animals lower in the scale, crabs are able to make good their injuries, though several moults are required to regenerate a limb.

Masking.—A common habit among crabs is that of masking themselves with foreign objects. Thus both the European species of *Maia* (*M. squinado* and *M. verrucosa*) are usually overgrown by Algae, Hydroids, and Polyzoa; the same is true of *Pisa*; in *Inachus* the long feet are especially well concealed by seaweeds; our common *Stenorhynchus* is often covered by a sponge growth; the Mediterranean *Dorippe lanata* uses its hind-legs to carry some living or dead object upon its back, and thus very emphatically asserts its innocence; the common *Dromia* (*D. vulgaris*) holds sponges on its back in similar fashion. See COMMENSALISM.

Intelligence.—As in several features of their structure, so in their intelligence, crabs appear to hold the highest place among crustaceans. Moseley observed how a sand-crab (*Ocypodaippeus*), which dreads the sea, dug itself into the sand and held on against the undertide of each great wave. Romanes refers to the alleged habit of the common crab in stationing a hard-shelled individual as sentinel during the moulting season. There seems to be not a little of the intelligent in some cases of crab-commensalism. Darwin has, however, given a crowning instance of intelligence which is worth many less emphatic. Some shells were thrown towards the hole of a burrowing shore-crab (*Gelasimus*). One rolled in, three remained a few inches from the mouth. In a few minutes the crab came

out, bearing the shell which had fallen in, and removed it to the distance of a foot. 'It then saw the three other shells lying near, and evidently thinking that they might likewise roll in, carried them to the spot where it had laid the first.'

Common British Forms.—The Common Shore-crab (*Carcinus maenas*); the Great Crab (*Cancer pagurus*), so much eaten; the Slender Spider-crab or Slender-beaked Crab (*Stenorhynchus tenuirostris*), with very long spider-like legs and bright

Slender Spider-crab (*Stenorhynchus tenuirostris*).

pink triangular body; the large Thorny Spider-crab (*Maia squinado*); the Common Swimming Crab (*Portunus variegatus*), common on Scotch coasts, with the last pair of legs flattened like oar-blades; the Velvet Fiddler-crab or Devil-crab (*Portunus puber*), with a brown hairy shell; the Masked Crab (*Corystes cassivelaninus*), with a carapace marked so as to suggest a mask, often found buried in the sand of English and Welsh coasts; the small Four-horned Spider-crab (*Pisa tetraodon*); the little Pea-crab (*Pinnotheres pisum*, &c.), inside bivalves, are familiar British species.

Classification.—Crabs are generally classified according to the shape of their cephalothorax into five families: (1) Catometopa, usually quadrangular—e.g. *Ocypoda*, *Grapsus*, *Pinnotheres*, *Gecarcinus*; (2) Cyclometopa, usually broad, narrowed behind, bow-shaped in front—e.g. *Telphusa*, *Cancer*, *Portunus*, *Carcinus*; (3) Oxyrhyncha, triangular, pointed in front—e.g. *Maia*, *Pisa*, *Hyas*, *Stenorhynchus*, *Inachus*; (4) Oxy stomata, usually round—e.g. *Calappa*, *Illa*; (5) Notopoda, with the last or last two pairs of limbs more or less turned back—e.g. *Dorippe*, *Porcellana*, *Lithodes*, *Dromia*.

See CRUSTACEA, CRAYFISH, HERMIT-CRAB, LOBSTER. Besides general works mentioned under Crustacea, see Balfour's *Embryology*; W. K. Brooks, *Handbook of Invertebrate Zoology* (Boston, 1882); Frédéricq, *Archiv. Zoologic Expér.* (1883); Huxley's *Invertebrates*; Romanes, *Animal Intelligence* (Inter. Sc. Series, 1886); Carus Sterne, *Werden und Vergehen* (1886); Woodward, in Cassell's *Natural History*.

Crab, ROGER, hermit, was born about 1621 in Buckinghamshire, and served for seven years (1642-49) in the Parliamentary army. He then set up in business as 'a haberdasher of hats' at Chesham, in his native county. He had imbibed the idea that it was sinful to eat any kind of animal food, or to drink anything stronger than water; and in 1651, determined to follow literally the injunction given to the young man in the gospel, he sold off his stock-in-trade, distributing the proceeds among the poor, and took up his residence in a hut. His food consisted of bran, turnip-tops, dock-leaves, and grass. The persecutions the poor man inflicted on himself caused him to be persecuted by others, cudgelled, and put in the stocks. He was four times imprisoned for sabbath-breaking and other offences, yet still he persisted in his course of life. He published *The English Hermit, Dagon's Downfall*, and a tract

against Quakerism'; and he died at Bethnal Green, 11th September 1680.

Crab-apple is a term applied somewhat vaguely to any sour and uncultivated variety, or species of apple. Thus *Pyrus spectabilis* of shrubberies is known as the Chinese Crab, *P. prunifolia* as the Siberian Crab, *P. coronaria* as the American Crab, and *P. baccata* of North Asia (including *cerasifera*) as the Cherry Crab. More strictly, however, the term is applied to the wild varieties of the true apple (*P. Malus*, var. *sylvestris*). Of this, again, two main varieties are distinguished, one smooth-leaved and sour (var. *austera*), the other more or less woolly-leaved and sweeter (var. *mitis*). The former of these may therefore be considered as the crab-apple proper.

Crabbe, GEORGE, poet, was born on Christmas Eve of 1754, at Aldelburgh, on the Suffolk seaboard. His father, 'salt-master' and warehouse-keeper, was a clever, strong, violent man; the mother, a meek, religious woman; and of three brothers, one perished captain of a slaver, another was lost sight of in Honduras. George, the eldest, got some schooling at Bungay and Stowmarket, then from 1768 to 1774 was surgeon's apprentice at Wickham-Brook and at Woodbridge. In his first place he had to help the ploughboy; in his second he fell in love with Sarah Elmy ('Mira'), who lived with her uncle, a wealthy yeoman, at the old moated hall of Parham. A spell of drudgery in his father's warehouse—nine months in London, picking up surgery cheaply—some three years' struggling practice at Aldelburgh—at last in April 1780, with £3 in his pocket, he sailed again for London, resolved to try his fortune in literature. Eight years before he had written verses for *Wheble's Magazine*; he had published *Inebriety, a Poem* (Ipswich, 1775); and now his *Candidate* soon found a publisher, unluckily a bankrupt one. A season of penury, dire as Chatterton's, was borne by Crabbe with pious bravery; he had to pawn clothes and instruments; appeals to Lords Thurlow, North, Shelburne, met no response; and early in 1781 he saw himself threatened with arrest for debt, when he made his case known to Burke. Forty-one years later he told Lockhart at Edinburgh, how, having delivered the letter at Burke's door, he paced Westminster Bridge all night long until daybreak. Burke proved a generous patron; from the hour of their meeting Crabbe was a 'made man.' He stayed at Beaconsfield; he met Fox, Johnson, and Reynolds; Thurlow gave him a bank-note for £100; Dodsley brought out his *Library*; and the very next winter he was ordained to the curacy of his native town. He resided as domestic chaplain to the Duke of Rutland at Belvoir Castle (1782-85); married Miss Elmy (1783); held four livings in Dorset, Leicester, and Lincoln shires, but spent thirteen happy years in Suffolk, at Parham, Great Glenham, and Rendham (1792-1805); returned to Muston, his Leicestershire rectory; and his wife having died there in 1813, exchanged it the next year for Trowbridge in Wiltshire. His gentle, kindly life, in which botanising had given place to fossil-hunting, was broken now and again by visits to London and its best society; he witnessed the Bristol riots (1831), as fifty-one years before he had witnessed those of Lord George Gordon; and on 3d February 1832 he died at Trowbridge.

Three novels, a treatise on botany, and poems untold all perished in great yearly 'incremations'; but still, Crabbe published *The Village* (1783), *The Newspaper* (1785), *The Parish Register* (1807), *The Borough* (1810), *Tales* (1812), and *Tales of the Hall* (1819), for which last and the earlier copyrights Murray paid him £3000. Of these poems Words-

worth wrote in 1832, 'They will last full as long as anything expressed in verse since first they made their appearance;' and Jane Austen said Crabbe was the only man whom she would care to marry. Byron, too, Scott, Jeffrey, Wilson, Lord Tennyson, Swinburne, Cardinal Newman, and, above all, Edward Fitzgerald, must be reckoned among his few votaries. 'Though nature's sternest painter, yet the best,' Byron's verdict upon him, is truer than Horace Smith's, 'a Pope in worsted stockings,' for this refers but to the accident of metre—the rhyming heroics, which, thirty per diem, Crabbe ground out anywhere. Their subject-matter, though, is all Crabbe's own. He is as much the poet of East Anglia as Scott of the Borderland or Wordsworth of the Lake Country. Its scenery and the life of its fisher-folk and peasantry he described with a realism greater than Zola's, if sometimes almost as tedious. Zola! nay, Crabbe has closer kinship to Balzac; and his strong, sombre pictures of sin and suffering are ever and again fit up with homely pathos and shrewd, Dutch-like humour. 'The tragic power of Crabbe,' Mr Swinburne says, 'is as much above the reach of Byron, as his singularly vivid, though curiously limited, insight into certain shades of character.' And in old John Murray's words, 'Crabbe said uncommon things in so common a way as to escape notice;' surely he claims notice from such as rank thought higher than expression.

An admirable Life by his son, the Rev. George Crabbe (1785-1857), for twenty-three years vicar of Bredfield, Suffolk, is prefixed to *Crabbe's Works* (8 vols. 1834). See also Mr Leslie Stephen's 'Hours in a Library' (2d series, 1876); Mr Fitzgerald's *Readings in Tales of the Hall* (1882); the essay on Crabbe by Mr W. J. Courthope in vol. iii. of Ward's *English Poets* (1884); and T. E. Kebbel's *Crabbe* (1888).

Crab-stones, or CRAB'S EYES. See CRAY-FISH.

Cracked Heels. From careless grooming, washing horses' legs and imperfectly drying them, permitting them to stand in accumulations of filth or exposed to draughts, the skin becomes inflamed, tender, itchy, thickened, and by-and-by cracked. An ichorous and fetid discharge exudes, and lameness often results. In animals with round *gunny* legs it is sometimes constitutional; underbred horses with rough hairy fetlocks present the majority of cases; white heels, being more delicate, are especially affected; whilst the hind limbs, exposed as they are to filth and cold, suffer most frequently. Cleanse carefully with tepid water; wash with a diluted solution of Goulard's Extract, or any other mild astringent; or dress occasionally with oxide of zinc ointment. Give, besides, a half-dose of physic, and a few mashes, afterwards carrots, swedes, or such laxative food, and where the ailment is persistent, use Diuretics (q.v.). When the skin is dry and irritable, poultice and apply glycerine before proceeding with astringents. In cold weather, and especially when the horse is heated, interdict washing the legs; but allow them to dry, and then brush off the dirt.

Cracovienne (krakowiak), the national dance of the Polish peasantry around Cracow. It has a very marked rhythm in $\frac{3}{4}$ time, and is often accompanied by singing. The Poles have a multitude of little ditties of two lines each, adapted to this music and dance.

Cracow (Pol. *Krakow*, Ger. *Krakau*), a city of the Austrian crown-land of Galicia, 259 miles NE. of Vienna by rail. It stands 672 feet above sea-level, in a wide, hill-girt plain on the left bank of the Vistula, which here becomes navigable, and is spanned by a bridge (1850) leading to Podgorze. The old walls have been converted into promenades,

and a line of detached forts now defends the city. Its older portion is a labyrinth of narrow, dark, and deserted streets, but contains many fine specimens of Gothic architecture in its churches and other edifices; and some handsome buildings are also to be seen in the more modern suburbs. On the Wawel rock, in the midst of the houses, rises the old castle of the Polish kings, degraded now to a barrack. The neighbouring cathedral (1320-59) is a splendid pile, containing the graves of John Sobieski, Poniatowski, Kosciusko, and many more heroes, with Thorwaldsen's statue of Christ. The university was founded in 1364, by Casimir the Great, and reconstituted under the Jagellons in 1394. Long the centre of light for Poland, it had decayed under Jesuit influence, but was reorganised and reopened in 1817, and now is attended by more than 800 students. It possesses a library of 150,000 volumes, and many MSS. of great value in connection with Polish history. Cracow has important fairs, and its trade and manufactures (chemicals, tobacco, beer, agricultural implements, &c.) have of late years greatly revived. Three miles west of the city is a grassy mound, 150 feet high, reared in 1820-23 to the memory of Kosciusko. It is composed of earth taken from all the patriotic battle-fields of Poland. The population has varied much at different periods, from 80,000 in the 16th century to 10,000 at the end of the 18th, 49,835 in 1869, and 66,095 in 1880, of whom 20,269 were Jews.

Cracow was founded by Krak, Prince of Poland, from whom it derives its name, about the year 700, became the capital of Poland in 1320, and continued such till 1609, when that honour was transferred to Warsaw. It was taken by the Bohemians in 1039, by the Tartars in 1241, by the Swedes in 1655 and 1702, and by the Russians in 1768. On the third partition of Poland, in 1795, it was assigned to Austria. From 1809 to 1815 it formed part of the duchy of Warsaw. The congress of Vienna established it as a republic, with a territory of 425 sq. m., and containing about 140,000 inhabitants, under the protectorate of Russia, Prussia, and Austria. Internal dissensions between the nobles and the common people afforded a pretence for interference, and the sympathy shown by the inhabitants of Cracow for the cause of Polish independence in 1830 and following years was made the ground of the annexation of Cracow to the Austrian dominions (1846). See POLAND, and the works of Essenwein (Leip. 1869) and Miltner (3d ed. Cracow, 1880).

Crag, a local term given specially to those masses of shelly sand which have been used from very ancient times in agriculture to fertilise soils deficient in calcareous matter. Geologists have used it to characterise several groups of strata. See PLIOCENE.

Crag and Tail, a term used to designate a peculiar hill conformation, in which a bold and precipitous front exists on one aspect of a hill, while the opposite is formed of a sloping declivity.

Castle Rock, Edinburgh.

Fine examples of this structure occur in and around Edinburgh, where the bold 'crag' faces the west and the 'tail' slopes towards the east; as, for example, the Castle rock, precipitous and unapproachable on every side except to the east. The

structure owes its origin to the juxtaposition of rocks of variable degrees of durability—the harder and more durable rocks having resisted denudation, and so protected the more readily eroded rocks that occur on the lee side of the former. The crag and tail phenomena of central Scotland and other regions which have been subjected to extreme glaciation (see GLACIAL PERIOD) is due to glacial erosion and accumulation. The crag faces the direction from which the ice came, and thus by opposing its advance induced excessive erosion upon the ground immediately in front. A hollow has thus usually been scooped out in this place, and continued along either side of the obstruction for some little distance. This somewhat crescent-shaped hollow is well seen on the west side of Edinburgh Castle rock, sweeping round on the north by Princes Street Gardens (the old Nor' Loch), and on the south by the valley of the Cowgate. The morainic material dragged along underneath the ice accumulated in the rear of the crag, so that the strata in that position are usually covered to a greater or less depth with boulder-clay, &c. The High Street of Edinburgh is thus built upon morainic materials.

Craig, JOHN, Scottish Reformer, was born in 1512, next year lost his father at Flodden, and was educated at St Andrews. He joined the Dominicans there, but fell under suspicion of heresy, and after a brief imprisonment (1536) went to Rome. Through Cardinal Pole he gained admission to the Dominican convent of Bologna, where he became the master of novices; next a copy of Calvin's *Institutes* fell in his way, and converted him to Protestantism. On 18th August 1559 he was lying in the dungeon of the Inquisition, condemned to suffer next morning at the stake, when Pope Paul IV. died, and the mob broke open the prisons, and set the prisoners at liberty. A bandit befriended him; a dog brought him a purse of gold as he was wandering helpless through a forest; he escaped to Vienna, and there preached in his friar's habit, one of his hearers being the Archduke Maximilian. Presently the new pope, learning his whereabouts, demanded his surrender; but Maximilian gave him a safe-conduct, and in 1560 he returned to Scotland. In 1563 he was appointed coadjutor to Knox, and with him was accused by the Earl of Bedford of having been privy to Rizzio's murder; in 1567 he incurred some censure for proclaiming, under strong protest, the banns between Queen Mary and Bothwell; and in 1572 he was sent to 'illuminate the dark places' in Angus and Aberdeenshire. He came back to Edinburgh in 1579 as a chaplain to James VI., took a leading part in the church's affairs, and had a share with Melville in the Second Book of Discipline. He was the author of the 'Confession of Faith' or first National Covenant, 'subscribed by the king's majesty and his household and sundry others' at Edinburgh, 28th January 1580. He withstood the restoration of prelacy; but his comparative moderation was not seldom displeasing to the 'popes of Edinburgh.' He died 12th December 1600. His *Short Summe of the whole Catechisme* (1581) has been reprinted in fac-simile, with a valuable introductory Memoir by T. G. Law (Edin. 1883).

Craig, THOMAS, writer on feudal law, was born in 1538, either at Craigfintray (Aberdeenshire) or in Edinburgh. From St Andrews he passed in 1555 to the university of Paris, and in 1563 was admitted an advocate at the Scottish bar, being next year appointed justice-depute of Scotland, and in 1573 sheriff-depute of Edinburgh. Whilst head of the criminal judicature, he did not neglect the muses, as was evidenced by an epithalamium on Queen Mary's marriage with Darnley and a poem on the

birth of James VI. Besides several more Latin poems, and the masterly *Jus Feudale* (1608; 3d ed. 1732), by which he is chiefly remembered, he wrote three other Latin treatises—on James VI.'s right to succeed to the English throne, on the advisability of a union between the two kingdoms, and on the homage controversy between Scotland and England. He stood high in favour with James, who wanted to knight him in 1603, and, on his declining, dispensed with the ceremony, but gave him the title. He died 26th February 1608. See his *Life* by P. F. Tytler (1823).

Craig-fluke (*Pleuronectes cynoglossus*), a flat fish in the same genus as Dab, Plaice, and Flounder (q.v.).

Craigleith Stone, a siliceous sandstone belonging to the lower carboniferous series, quarried at Craigleith, 2 miles W. of Edinburgh, and largely used for building in that city, for which it is admirably adapted by its purity and durability.

Craik, GEORGE LILLIE, a versatile and industrious author, born at Kennoway, Fife, in 1798, was educated for the church at St Andrews University, but, preferring a literary career, came to London in 1826, and formed a connection with Charles Knight. His first work of importance was the *Pursuit of Knowledge under Difficulties* (1831). He also contributed largely to the *Penny Magazine* and *Cyclopædia*, and in 1839 became editor of the *Pictorial History of England*, some of the most valuable chapters of which were written by himself. From these his *Sketches of the History of Literature and Learning in England* (6 vols. 1844) and his *History of British Commerce* (3 vols. 1844) were reprinted. In 1849 Craik was appointed to the chair of History and English Literature in Queen's College, Belfast, a situation which he occupied till his death on 25th June 1866. His other works include *Spenser* (1845), *Bacon* (1846-47), *Romance of the Peerage* (1848-50), *The English of Shakespeare* (1856), *History of English Language and Literature* (1861; 9th abridged ed. 1883).—His youngest daughter, Georgina Marion Craik, born in London in 1831, began to write at nineteen, and had published more than two dozen novels up till 1888.

Craik, MRS. Dinah Maria Mulock, well known as the author of *John Halifax, Gentleman*, was born at Stoke-upon-Trent in 1826. She early took the burden of supporting an ailing mother and two younger brothers, and wrote stories for fashion-books, as well as for graver publications. Her first serious appearance as a novelist was in 1849, with her story *The Ogilvies*, which was followed by *Olive*, *The Head of the Family*, and *Agatha's Husband*. But she never surpassed or even equalled her domestic novel *John Halifax* (1857), which has had, and still continues to have an extraordinary popularity, and has been translated into French, German, Italian, Greek, and Russian. The scene is laid at Tewkesbury, where a marble medallion has been placed to her memory in the abbey. A pension of £60 a year, awarded to her in 1864, she set aside for authors less fortunate than herself. In 1865 she married Mr George Lillie Craik, a partner in the publishing house of Macmillan & Co. (nephew of the subject of the preceding article, and spent a period of quiet happiness and successful literary industry at her home, Corner House, Shortlands, Kent, where she died 12th October 1887. Much of Mrs Craik's verse is collected in *Thirty Years' Poems* (1881). She wrote a good deal for the magazines, and produced in all forty-six works, viz.—fourteen more novels, and several volumes of prose essays, including *A Woman's Thoughts about Women* (1858), and *Concerning Men, and other Papers* (1888). See

Mrs Oliphant's sketch in *Macmillan's Magazine* (1887).

Craill, an antique little coast-town in the 'East Neuk' of Fife, 2½ miles WSW. of Fife Ness, 10 SE. of St Andrews, and 43 NE. of Edinburgh by rail. There is a fragment of a castle of David I.; and the church, which was made collegiate in 1517, is an interesting Second Pointed structure. John Knox here preached his 'idolatrous sermon,' 9th June 1559; and in 1648, James Sharp was appointed minister. The fishing is not what it once was, and the harbour has little trade; but Craill is a pleasant summer-resort. It was made a royal burgh in 1306, and unites with the other six St Andrews burghs to return one member to parliament. Pop. (1861) 1238; (1881) 1148.

Crake. See CORN-CRAKE.

Crambé, a genus of Crucifere, having a pod (*siliqua*) of two unequal joints, of which the upper is globose and one-seeded, the lower abortive. *C. maritima* is well known as Sea-kale (q.v.). *C. tartarica*, of Eastern Europe, with much divided leaves and a great fleshy root, is cultivated in Roumania as cauliflower, and its root is eaten either boiled or in salads.

Cramer, JOHANN BAPTIST, pianist, was born at Mannheim in 1771, the son of Wilhelm Cramer (1745-99), a musician of repute, who settled in London in 1772. From 1788 the son undertook concert tours on the Continent, and gained a high reputation as a facile and expressive performer. He founded the musical publishing firm which bears his name in 1828, and after some years' residence in Paris, died in London, 16th April 1858. Most of his compositions are now forgotten, but his series of *Studies* is a work of importance.

Cramp is a word applied to muscular contractions of an irregular kind, in a somewhat variable way.

(1) In its common use, it denotes an involuntary and painful contraction of a voluntary muscle or group of muscles. It is most apt to occur when a muscle has been fatigued; though any muscle may be affected, those of the calves most often suffer. It is especially common in pregnant women and persons of a gouty diathesis, and is a prominent feature in some diseases, especially cholera. There is no specific for preventing it; each case must be treated on its merits. The contraction and accompanying pain is usually cut short if the affected muscle be stretched—e.g. in the case of the calf-muscles, the knee must be straightened and the foot bent up as far as possible towards the front of the leg, to lengthen the affected muscles to the utmost, and similarly with other cases.

(2) *Writer's Cramp* is the commonest and best known of a group of diseases called *trade spasms*. The person affected can use his fingers for any purpose, even the most delicate manipulations, so long as he does not attempt to write; but whenever he does so, the muscles refuse to obey his will, and the pen either drops from his hand or executes spasmodic purposeless movements. Similar conditions may occur in telegraphists and pianists—in fact, in any case where frequent and continued use of particular muscular actions is necessary. These distressing and troublesome affections have recently been cured in some cases by means of Massage (q.v.) and systematic gymnastic exercises of the affected parts.

(3) *Bather's Cramp*.—A good swimmer, while bathing, is seen to throw up his arms, perhaps is heard to cry out once, and then sinks to rise no more. It is said that 'bather's cramp' has been the cause of his death. This phrase, however, is merely an apology for ignorance: what has happened, and whether it is the same in all

apparently similar cases is as yet quite uncertain. Cramp, in the ordinary sense, of one or more limbs, though very embarrassing and alarming, would not be so disastrous to a practised swimmer as to make him sink without a struggle; and, though common in bathers, cannot be accepted as the cause of all the fatal accidents like that described above. Of other theories advanced, the most probable is that sudden failure of the heart's action, a partial or total faint, is the cause of the calamity, at least in very many cases. A sudden plunge into cold water by itself causes some strain upon the heart; and swimming, about the most severe of all forms of exercise, increases its work very greatly—sometimes, it is easy to believe, beyond safe limits. The recorded experience of some who have narrowly escaped death from this cause makes it appear extremely probable that it is the real explanation of at least some of these sad accidents. No one when out of practice should attempt a long swim in cold water; and persons with weak hearts should be especially careful to avoid fatiguing themselves when bathing.

Cramp Rings were rings which were supposed to cure cramp and the 'falling-sickness.' They are said to have originated as far back as the middle of the 11th century, in a ring presented by a pilgrim to Edward the Confessor, which, after that ruler's death, was preserved as a relic in Westminster Abbey, and was applied for the cure of epilepsy and cramp. Hence appears to have arisen the belief that rings blessed by English sovereigns were efficacious in such cases; and the custom of blessing for distribution large numbers of cramp rings on Good Friday continued to exist down to the time of Queen Mary. The accomplished Lord Berners, ambassador to Spain in Henry VIII.'s time, writes from Saragossa to Cardinal Wolsey: 'If your grace remember me with some crampe ryngs ye shall doo a thing muche looked for; and I trust to bestow thaym well with Goddes grace.' The metal rings were composed of what formed the king's offering to the cross on Good Friday, usually either gold or silver. The superstitious belief in the curative property of cramp rings made out of certain pieces of silver obtained in particular ways still lingers in some districts of England.

Cran (Gaelic), a measure of capacity in Scotland for herrings when just taken out of the net. It amounts to 37½ imperial gallons, and comprises about 750 herrings on an average.

Cranach, LUCAS, a celebrated German painter, so named from Kronach in the bishopric of Bamberg, Upper Franconia, where he was born, 4th October 1472. Little is known of his early life, but he seems to have been instructed by his father, and, possibly, by Matthew Grundewald; to have resided in Gotha, where he married Barbara Brengbier; and to have accompanied Frederick the Wise, Elector of Saxony, to the Holy Land in 1493. Certainly he was befriended by that prince, and was his court-painter at Wittenberg, an appointment which he received in 1508, along with a patent of nobility, and the 'motto,' or *kleinod*, of a crowned and winged serpent, with which he marked his subsequent works, instead of (sometimes in combination with) the initials which he had previously used. Monopolies for printing and the sale of medicine were also bestowed upon him. The house in which he carried on his manifold occupations was standing at Wittenberg till 1871, and his importance in the town may be gathered from the fact that in 1537, and again in 1540, he was elected a burgomaster. In 1509 he accompanied an embassy to the Emperor Maximilian, and while in the Netherlands he portrayed the

prince, afterwards Charles V., then a boy of nine. After the death of the Elector Frederick in 1525, he was continued in his official position by his brother, and also by his successor, John Frederick the Magnanimous, whose captivity at Augsburg the artist shared, and whose release he is believed to have procured from the emperor in 1552. He returned with his master to Weimar, and died there on 16th October of the following year. The superiority of his earlier works, both in painting and engraving, is doubtless to be accounted for by the fact that in later life the pressure of numerous commissions necessitated the assistance of his sons, and of many other pupils. His paintings, executed in oils on panel, include sacred and a few classical subjects, hunting-scenes, and portraits.

His drawing is commonly hard and defective, but his colouring is rich, warm, and effective, and a certain homely earnestness, sometimes mingled with humour, characterises his productions. A quaint portrait of a girl in an elaborate costume from his hand is in the National Gallery, London. He was closely associated with the German Reformers, many of whom were portrayed by himself and his pupils. Figures of Luther and Melancthon, and the painter himself, are introduced in his 'Crucifixion' in the Stadtkirche, Weimar, a work engraved in Waagen's *Handbook of Painting* (ed. of 1874), and usually regarded as the artist's most important composition. Three of his copper engravings, dated 1519, 1520, and 1521, represent Luther; and among his other principal works with the burin are 'The Penitence of St John Chrysostom' (1509), and a portrait of the Elector Frederick. His wood-engravings are more numerous, including 'The Passion,' 15 cuts; 'The Martyrdom of the Apostles,' 12 cuts; and 'The Wittenberg Hagiology,' 119 cuts. He had three sons, all of whom were painters.—The second of them, LUCAS, the younger, born 1515, was a burgomaster of Wittenberg. He painted in the manner of his father, and their works are difficult to distinguish, especially as both artists used a similar mark. According to Schuchardt, however, in the productions of the son the crowned serpent appears with the wings folded, instead of erect as in those of the father. His 'Crucifixion,' or 'Nativity,' and a picture of 'The Lord's Vineyard,' symbolical of the progress of the Reformation, are in the Stadtkirche at Wittenberg, and his works may also be studied in Berlin, Munich, and at Dresden, where are his portraits of the Electors Maurice and Augustus, and a 'Crucifixion.' He died at Wittenberg in 1586.

Cranberry (*Oxycoccus*), a north temperate and arctic genus of small evergreen shrubs of the order Ericaceæ (sub-order Vaccineæ). The only British species (*O. palustris*, formerly *Vaccinium Oxycoccus*) grows in peaty bogs and marshy grounds, and is a small wiry shrub with creeping thread-like branches, and small oval leaves rolled back at the edges. Large quantities of the fruit, which is chiefly used for making tarts, are collected in some parts of Britain, as also in Germany and other European countries, although the draining of bogs has now made it scarce where it was once plentiful. The berries are an excellent antiscorbutic, and hence furnish an excellent addition to sea stores. Wine is made from them in Siberia, and a beverage made from them is sold in the streets of St Petersburg.—The American Cranberry (*O. macrocarpa*) is of similar distribution, but is a larger and more upright plant, with bigger leaves and berries. The berries are not now collected by means of a rake, but by hand, as the former method bruises them. Large quantities are exported to Europe, and the berries are also imported into Britain from Russia and other parts of northern Europe. Both kinds may be cultivated in

gardens, in a peat-soil kept very moist or round the margin of a pond.—The berries of the Red Whortleberry or Cowberry (*Vaccinium Vitis-Idæa*) are sold under the name of cranberries in Aberdeen and

Cranberry (*Oxycoccus palustris*):
a, flower; b, fruit.

other places, and are used in the same way.—The Tasmanian Cranberry is the fruit of *Astroloma humifusum*, a pretty little trailing Epacridaceous shrub; while in Australia the same name is given to other plants of the same order, notably *Styphelia ascendens* and *Lissanthe sapidæ*.

Cranborne, VISCOUNT, the courtesy title of the eldest son of the Marquis of Salisbury.

Cranbrook, a pleasant little market-town in the Weald of Kent, 46 miles SE. of London. It has a fine Perpendicular church, and a large trade in hops. From the 14th to the 17th century it was the centre of the broadcloth manufacture introduced by the Flemings. Pop. of parish (1881) 4216. See Tarbutt's *Annals of Cranbrook* (1875).

Cranbrook, GATHORNE GATHORNE-HARDY, VISCOUNT, was born 1st October 1814, at Bradford, the son of John Hardy, Esq., of Dunstall Hall, Staffordshire. Educated at Shrewsbury and at Oriel College, Oxford, where he took his B.A. in 1837, he was called to the bar in 1840, and in 1856, after unsuccessfully contesting Bradford nine years earlier, was returned as a Conservative by Leominster. In 1865 he defeated Mr Gladstone in the celebrated Oxford University election; in 1878 he was raised to the peerage as Viscount Cranbrook. He was Under-secretary of State for the Home Department (1858-59), President of the Poor-law Board (1866-67), Home Secretary (1867-68), War Secretary (1874-78), Secretary of State for India (1878-80), and Lord President of the Council (1885-89).

Crane (*Grus*), a genus of birds in the order Grallatores, the type of the family Gruide. This family differs from herons, storks, &c., in having the hind-toe placed higher on the leg than the front ones, and in certain characters of bill and skull. The members are also less addicted to marshy places, and feed not only on animal, but, to a considerable extent, on vegetable food. The cranes are all large birds, long legged, long necked, long billed, and of powerful wing. Some of them perform great migrations, and fly at a great height in the air. Some twelve species are known, mostly in the palaearctic region, but also in Asia, Australia, and America. Unlike other Grallatores, the young cranes are helpless and require to be fed. Only two eggs are laid.—The Common Crane (*G. cinerea*) breeds in the northern parts of Europe and Asia, retreating in winter to tropical or subtropical regions. Flocks of cranes periodically pass over the southern and central countries of Europe, uttering their loud

harsh cries in the air, and occasionally alighting to seek food in fields or marshes. The crane, when standing, is about four feet in height; the prevailing colour is ash-gray; the head bears bristly feathers, and has a naked crown, reddish in the male; the bill, which is longer than the head, is reddish at the root, dark green at the apex; the feet are blackish; the tail is short and straight. They are very stately birds, though their habit of bowing and dancing is often grotesque. The covering feathers of the wings are elongated, reaching beyond the ends of the primaries, and their webs are unconnected; they are varied and tipped with bluish-black, and are the well-known plumes once much used in ornamental head-dresses. The visits of the crane to Britain are now very rare, although in former times they were comparatively frequent. It feeds on roots, seeds, &c., as well as on worms, insects, reptiles, and even some of the smallest

Crane (*Grus cinerea*).

quadrupeds. The flesh is much esteemed. Cranes use their bill as a dagger, and when wounded are dangerous to the eyes of a rash assailant. They may be readily tamed in captivity and exhibit great sagacity.—The Whooping Crane (*G. americana*) is considerably larger than the common crane, which it otherwise much resembles except in colour; its plumage, in its adult state, is pure white, the tips of the wings black. It spends the winter in the southern parts of North America. In summer it migrates far northwards, but rather in the interior than the eastern parts of the continent.—To the crane family belong also the Demoiselles—e.g. *Anthropoides virgo*, from southern Europe to central Asia, and the Ethiopian Balearic Cranes—e.g. *Balearica pavonina*. See Blyth, *Natural History of the Cranes* (1881).

Crane, a machine for lifting weights, worked either by hand, or by steam, or by hydraulic power. The most common hand form consists of an upright revolving post and a projecting arm (usually at an angle of about 45°), the jib with a fixed pulley at its extremity. The lifting chain or rope is secured to the weight, passes over the fixed pulley, and then round a drum or cylinder; suitable toothed-wheel gearing worked by a handle revolves this drum, and thus winds up or unwinds the rope or chain, and so raises or lowers the weight, while at the same time the effort applied by the men at the handles is greatly magnified—namely, disregarding frictional losses, in the same proportion that the peripheral speed of the handles is reduced by the gearing interposed between handle axis and drum axis. The revolving motion of the upright post enables the load to be deposited at any point within the sweep of the jib. It is often arranged that the jib shall be hollow; the chain then passes down it, and there

is no fear of fouling; if also the jib is of a curved form, we obtain the full benefit of the lift, while in

the ordinary crane the form of the jib or the tie interferes with the usual height of lift.

Whenever much hoisting or heavy work has to be done, steam or hydraulic power is always used; the cranes are then either stationary or portable, the latter type being used whenever it is more convenient to move the crane to its work than the converse. The stationary power cranes differ from the hand ones mainly in their vastly greater power, and consequently greater size and complexity of gearing; where steam is used there are generally two direct-acting steam-cylinders, which replace the two handles worked by hand. The very powerful stationary cranes used in docks capable of lifting 50 to 75 tons are examples of this kind; they are always mounted on massive foundations, and so arranged as to sweep a whole circle. Hydraulic power is very largely used in cranes for these places and in great steel-works; they are simpler in construction, a good deal of gearing being done away with; the water in the operating cylinder is always under great pressure, usually 700 lb. on the square inch. In the hydraulic cranes originally introduced by Sir William Armstrong & Co., the power given out by the hydraulic cylinder is reduced by using systems of pulleys in the inverse order, the lifting chain being attached to the cylinder, then passing over a pulley fixed to the head of the ram, then round other fixed pulleys, and so up to the fixed pulley at jib end, the effect being to increase the motion of the ram, and so secure very rapid lifts at the expense of using more power. In one very ingenious steam-crane (Morrison's) the post of the crane is hollow, and forms the steam-cylinder, in which works a piston with flexible piston-rod—namely, the lifting chain; this form is very steady and very readily slewed.

Portable cranes are mounted on plain railway trucks, either of wood or iron. This truck carries firmly attached to it a central post, the whole of the rest of the crane being carried on a strong base-plate capable of revolving round this post as a pivot, the boiler being so placed (often standing on its own feed-water tank) on this base-plate that it forms a counterbalance to the weight to be lifted. The boiler is always of the vertical type, and very simple in its internal arrangements of tubes (see fig.), because it often has to work with very dirty feed-water. The gearing is usually carried by A frames bolted to the base-plate; the engine, having generally two small direct-acting steam-

cylinders, is easily reversed; by means of gearing and clutches, which are operated by the man in charge of the crane by hand or foot levers, the engine can perform the following operations: (1) Lower or raise the outer end of the jib; (2) slew the crane—i.e. the base-plate and all it carries; (3) propel the truck along the rails; (4) hoist the loads. For the last three operations the gearing is generally so arranged that there are two speeds, a quick and a slow, either of which can be used, depending on the work to be done. The figure shows a very common type of this kind, which will lift from 5 to 7 tons, according to the position of the jib. For the maximum load the chain end is often attached to end of jib, and then round a hanging-block, and so up to fixed pulley at jib end, thus doubling pull on chain. For the same purpose as the ordinary crane are used contrivances known as derricks, which consist essentially of a mast or tripod with a long cross-boom at the top, tied to the mast by guys; pulley-blocks attached to one arm of the boom form the means of lifting. They are a good deal used in America for very heavy work, such as raising wrecks, bridge-building, &c. They readily lend themselves for use as floating-cranes, since by making the vessel carrying them in watertight compartments which can be filled, it is a very easy matter to counter-balance the load.

Crane, THOMAS FREDERICK, a learned folklorist, was born in New York city, July 12, 1844. He was educated at the public school and academy of Ithaca, New York; and graduated at the college of New Jersey (Princeton) in 1864; A.M. in 1867; and Ph.D., *causa honoris*, in 1874. He was appointed assistant-professor of Modern Languages in Cornell University in 1868, professor of Spanish and Italian there in 1872, and professor of Romance Languages in 1881. Professor Crane has contributed a large number of articles to the *North American Review*, *International Review*, *Harper's Magazine*, *Lippincott's Magazine*, and *The Nation* on folklore and the literary history and philology of the Romance languages, especially during the period of the middle ages. Since his article on Italian folk-tales in the *North American Review* for July 1876, he has devoted much attention to the subject of the origin and diffusion of popular tales, and was one of the founders of the American Folklore Society (1888). Among his books are *Italian Popular Tales* (Boston, 1885); *Le Roman-tisme Français* (New York, 1887); and an edition (1889), for the English Folklore Society, of the *Exempla* or illustrative stories contained in the *sermones vulgares* of Jacques de Vitre, Bishop of Acre (died 1240), containing the Latin text, translation into English, elaborate notes on the origin and diffusion of the individual stories, and an introduction on the life of the author, and the use of illustrative stories in medieval sermons, &c. Professor Crane's *Italian Popular Tales* forms, from its extent, its scientific accuracy, and the wide learning of its notes, one of the most important of recent contributions to storiology.

Crane, WALTER, subject-painter, was born at Liverpool, 15th August 1845, the son of an artist, Thomas Crane (1808–59). He himself was trained as an artist, and his earlier as well as much of his later work consists of book-illustrations. Among these may be named his series of 'Toy-books' (1869–75), 'The Baby's Opera' (1877), and 'The Sirens Three,' in which last the poem as well as the designs was his work. In 1862 he began to exhibit paintings at the Royal Academy, showing in that year 'The Lady of Shalott'; and he was a constant contributor to the Grosvenor Gallery from

its foundation in 1877 till 1888. His pictures nearly always deal, in a somewhat decorative and archaic fashion, with subjects of an imaginative nature, such as 'The Riddle of the Sphinx' (1887). He has also produced many very delicate and refined landscape subjects in water-colours; and has designed wall-papers and interior decorations. In 1888 he was elected a member of the Royal Society of Painters in Water-colours.

Crane-fly. See DADDY LONG-LEGS.

Crane's-bill. See GERANIUM.

Crananore (properly *Kodungalūr*), a town in Cochin state, on the west coast of southern India. It stands on one of the openings of the great Cochin backwater, 18 miles N. of Cochin town; pop. about 10,000. The place is of great historical interest. It is the traditional scene of St Thomas's labours. The Syrian Christians were certainly established here before the 9th century, and the Jews' settlement was probably still earlier. Possessed by the Portuguese, it was taken from them by the Dutch in 1661; was seized by Tippoo in 1776, retaken, sold, and destroyed and abandoned by Tippoo in 1789.

Craniology. See SKULL, ETHNOLOGY.

Crank, in Machinery, is a lever or arm on a shaft, driven by hand (e.g. a winch-handle), or by a connecting-rod, its object being to convert reciprocating motion into rotary motion. Engine-cranks which convert the to and fro motion of the piston into continuous rotation of crank-shaft are connected to the piston-rod end by the connecting-rod. They are, when single, of steel, wrought-iron, or cast-iron, the crank in this case being either a simple arm, enlarged at one end to fit over the shaft, and with a pin at the other end embraced by the rod end (fig. 1); or else a disc centred on the shaft, with crank-pin as before (fig. 2). This last form is well balanced. When double, as is usual in large engines (fig. 3), they are now often built up

of steel, the two arms being shrunk on to the shaft, and pin on to them. In two positions during each turn, a connecting-rod exerts no power of rotation. These are when rod A and crank-arms B are parallel (as in fig. 3 and opposite position), and are the *dead centres*; all the push or pull of the rod only causes pressure on shaft-bearings. To carry the crank over these points either a heavy wheel (fly-wheel) is attached to the shaft, which stores up energy during other parts of the revolution, and gives it out at these points, or else two or more cranks are so placed on the shaft that when one is on its dead centre, the others are exerting nearly their maximum effort, which is when rod and crank are at right angles.

Cranmer, THOMAS, Archbishop of Canterbury, was born of a good old family at Aslacton, Nottinghamshire, 2d July 1489. He learned his grammar of 'a rude parish clerk,' a 'marvellous severe and cruel schoolmaster,' who seems to have permanently cowed his spirit; still, his father trained him in all manly exercises, so that even

as primate he feared not to ride the roughest horse, and was ever a keen hunter. By his widowed mother he was sent in 1503 to Jesus College, Cambridge, where in 1510 he obtained a fellowship. He forfeited it by his marriage with 'black Joan' of the Dolphin tavern, but regained it on her death in childhood before the year's grace was up; and taking orders in 1523, proceeded D.D., and became a divinity tutor. During the quarter of a century that he resided at Cambridge he did not greatly distinguish himself; Erasmus never so much as mentions him; he was just a clever, hard-reading college don.

But in the summer of 1529 the plague was raging in Cambridge, and Cranmer removed with two pupils to Waltham. Here he met Fox and Gardiner, the king's almoner and secretary; and their talk turning on the divorce, Cranmer suggested that Henry might satisfy his conscience of the nullity of his first marriage by an appeal to the universities of Christendom. The suggestion pleased Henry; he exclaimed, 'Who is this Dr Cranmer? I will speak to him. Marry! I trow he has got the right sow by the ear.' So Cranmer became a counsel in the suit. He was appointed a royal chaplain and archdeacon of Taunton; was attached to the household of Anne Boleyn's father (Anne at the time being Henry's paramour); penned a treatise to promulgate his view; and was sent on two embassies, to Italy in 1530, and to Germany in the middle of 1532. At Rome the pope made him grand penitentiary of England; at Nuremberg he had married a niece of the Reformer Osiander—a marriage uncanonical but not then illegal—when a royal summons reached him to return as Warham's successor in the see of Canterbury. He sent his wife secretly over, and himself following slowly, was consecrated on 30th March 1533, four days after the arrival of the eleven customary bulls from Rome. He took the oath of allegiance to the pope, with a protest that he took it 'for form sake, and with, as was usual, a contradictory oath of allegiance to the king.

That Henry looked for a pliable judge in Cranmer no man could doubt, least of all Cranmer himself, who in May pronounced Catharine's marriage null and void *ab initio*, and Anne's, four months earlier, valid; and who in September stood godfather to Anne's daughter Elizabeth. It was the samethroughout the entire reign. Cranmer annulled Henry's marriage with Anne Boleyn (1536), divorced him from Anne of Cleves (1540), informed him of Catharine Howard's prenuptial frailty, and strove to coax her into confessing it (1541). Sometimes he raised a voice of timid entreaty, on Anne Boleyn's behalf, on Cromwell's; still, if Henry said they were guilty, guilty they needs must be. He did what he dared to oppose the Six Articles (1539), naturally, since by one of them the marriage of priests was rendered felony, punishable with death; but he failed to stick to his opposition, and sent away his own wife to Germany, whence he did not recall her till 1548.

A kindly, humane soul, yet he was not ahead of his compeers—More, for instance, or Calvin—in the matter of religious toleration. We cannot acquit him of complicity in the burning of Frith and Lambert for denying the doctrine of Transubstantiation (1533-38), of Friar Forest for upholding the papal supremacy (1538), of two Anabaptists, a man and a woman (1538), of Joan Bocher for denying Christ's humanity (1550), and of a Dutch Arian (1551). In the death, however, of Anne Askew (q.v.) he seems to have borne no part; nor is there one word of truth in Foxe's legend that he coerced Edward VI. into signing the warrant for Joan Bocher's execution. With the dissolution of the monasteries he had little to do; but he

bestirred himself in promoting the translation of the Bible (q.v.) and a service-book, in curtailing the number of holy days, in the suppression of the cult of St Thomas of Canterbury, and in negotiating an eirenicon with foreign Reformers. On the path, indeed, towards Protestantism, he was ever in advance of Henry VIII., though to Henry he surrendered his right of private judgment as completely as ever Ultramontane to Pope. Thus, writing in 1540 on the sacraments, he could wind up a thesis with 'This is mine opinion and sentence at this present, which nevertheless I do not temerariouly define, but remit the judgment thereof wholly unto your majesty.' Henry repaid him with implicit confidence, and twice saved him from the plots of his enemies (1543-45).

On 28th January 1547 Henry died, and Cranmer sang mass of requiem for his soul. He had been slowly drifting into Protestantism; but now the inrushing tide swept him onward through all those religious changes by which the mass was converted into a communion—changes stereotyped in the Second Prayer-book of 1552. See ENGLAND (CHURCH OF), PRAYER-BOOK, ARTICLES, HOMILIES, CATECHISM. During this as during the preceding reign he meddled little with affairs of state, though he was one of the council of regency. What he did do was not too creditable. In gross violation of the canon law he signed Seymour's death-warrant; he had a chief hand in the deposition and imprisonment of Bishops Bonner, Gardiner, and Day; and won over by the dying boy-king's pleading, he reluctantly subscribed the instrument diverting the succession from Mary to Lady Jane Grey (1553). Herein he was guilty of conscious perjury, yet, the twelve days' reign over, he made no attempt to flee. On the contrary, he was roused to an outburst of indignation, rare with him, by a report that he had offered to restore the mass, had indeed restored it at Canterbury. In the heat of the moment he dashed off a letter, denouncing that report as a lie of the devil, which letter, unrevised, being prematurely circulated, on 14th September Cranmer was sent to the Tower, on 13th November was arraigned for treason, and, pleading guilty, was condemned to die. If he had been executed on that sentence, little could have been urged against his executioners, but he was reserved to be tried as a heretic, and, perchance, to recant his heresy. In March 1554 he was removed with Ridley and Latimer, to Bocardo, the common gaol at Oxford. He bore himself bravely and discreetly in a scholastic disputation, as also upon his trial before the papal commissioner, whose jurisdiction he refused to recognise. In October from the gaol he witnessed Latimer's and Ridley's martyrdom; in December judgment was pronounced against him; and on 14th February 1556 he was formally degraded, stripped of the mock vestments in which they had arrayed him. And now in rapid succession he signed form after form of recantation, seven in all, each more submissive than its predecessor. The last he transcribed on the morning of 21st March, and forthwith they brought him to St Mary's Church. If not before, he learned at least now from the sermon that he must burn; anyhow, when they looked for him to read his recantation, instead he retracted all that 'for fear of death' his hand had written 'contrary to the truth.' With a cheerful countenance he then hastened to the stake, and, fire being put to him, thrust his right hand into the flame, and kept it there, crying: 'This hath offended! Oh this unworthy hand!' Very soon he was dead.

Among Cranmer's forty-two writings, the chief of which have been edited by the Rev. H. Jenkyns (4 vols. 1833) and the Rev. J. E. Cox (2 vols. Parker Society, 1844-46), may be noticed his

prefaces to the Bible (1540) and the First Prayer-book (1549); the *Reformatio Legum Ecclesiasticarum*—his revision, happily abortive, of the Canon Law (q.v.)—first published in 1571; and *A Defence of the True and Catholic Doctrine of the Sacrament* (1550).

See *Narratives of the Reformation*, edited by J. G. Nichols (Camden Society, 1859), with a sketch of Cranmer by Ralph Morice, his secretary; Foxe's *Acts and Monuments*; Cooper's *Athenæ Cantabrigienses* (1858); Mr Gairdner's article in the *Dictionary of National Biography* (vol. xiii. 1888); Strype's *Ecclesiastical Memorials* (1721); Shakespeare's *Henry VIII.* and Lord Tennyson's *Queen Mary*; and the *Lives of Cranmer* by Strype (1694), Gilpin (1784), Todd (2 vols. 1831, with fine portrait), Le Bas (2 vols. 1833), Dean Hook, *Lives of the Archbishops* (vols. vi.-vii. 1868), and Collette (1887).

Cranmog, from the Gaelic *cran*, 'a tree,' a modern term employed to designate a species of lake-dwelling common in Scotland and Ireland, which consisted of an islet wholly or partially built up from the bottom of the loch by masses of brush-wood, steadied by piling, and consolidated by stones and gravel, the whole being surmounted above the level of the water by a platform of timber, earth and stones, on which were wooden huts, often surrounded by palisades for better security. The earliest occurrence of the word in historical documents is in the Register of the Privy-council of Scotland in 1608, when the 'Crannokis of the Ylig' are classed with 'houssis of defence and strongholds' to be given up to the king. See LAKE-DWELLINGS.

Crape, a thin fabric made of silk, which has been tightly twisted, without removing the natural gum with which it is covered when spun by the worm. It is woven as a thin gauze, then boiled to extract the gum, which causes the threads partially to untwist, and thus gives a waved and rough appearance to the fabric. It is usually dyed black, and used for mourning apparel. The nature of the finishing processes in the making of crape is kept secret by European manufacturers. In Japan, crape is manufactured by using alternately weft threads twisted in opposite directions, and these are of a much closer twist than ordinary threads. When the piece is woven it is dipped in cold, then in hot, and again in cold water in rapid succession, and afterwards rolled and dried. The effect of these operations on the weft threads produces the crisp surface. Chinese and Japanese crapes are often white, with coloured designs, or in single colours, and used for shawls, scarfs, &c.

Crashaw, RICHARD (circa 1613-49), an English religious poet, was the son of a clergyman in the English Church, and was born in London about 1613. He was educated at the Charterhouse, and at Cambridge, where he obtained a fellowship at Peterhouse in 1637. His leanings towards Roman Catholicism prevented him from receiving Anglican orders, and in 1644 he was ejected from his fellowship by the parliament for refusing to take the Covenant. He went to Paris, adopted the Roman Catholic faith, and suffered great pecuniary distress, until about 1648, through Cowley's influence, he was introduced to Queen Henrietta Maria, who recommended him to certain dignitaries of the church in Italy. He obtained a humble office in the household of Cardinal Palotta, but in April 1649, a few months before his death, he became sub-canon of the church of Our Lady of Loretto. In 1634 Crashaw published a volume of Latin poems, *Epi-grammatum Sacrorum Liber* (2d ed. 1670), in which appeared the famous line on the miracle at Cana:

'Nympha pudica Deum vidit et erubuit'

(The modest water saw its God and blushed).

In 1646 appeared his *Steps to the Temple; Sacred Poems, with other Delights of the Muses*—in which

there is much fervid poetry. The title of this collection, which is due to the editor, not the author, refers to its affinity with George Herbert's *Temple*. An edition (the third) was published at Paris in 1652, under the title *Carmen Deo Nostro*, with 12 vignette engravings designed by Crashaw. A collective edition of Crashaw's works was published in 1838, at London, by W. D. Turnbull, and a fuller edition in 1872 by Dr A. B. Grosart. Crashaw greatly resembles George Herbert in his cast of thought, and is not inferior to him in richness of fancy, though his conceits are more strained, and less under the control of taste. His devotional strains exhibit great copiousness and beauty of language.

Crassulaceæ, an order of calycifloral dicotyledons, allied to the Saxifragæ, are herbaceous or sometimes shrubby plants, always more or less succulent. About 400 species are known in the genera, chiefly from warm and temperate countries and in dry, sunny situations. South Africa and Mexico are peculiarly rich in species. *Sedum* (stone-crop) and *Sempervivum* (house-leek) are the most familiar genera. These and allied forms, such as *Echeveria*, are largely used for bedding-out purposes, grown on rockwork, or cultivated in the 'succulent-house.' *Crassula coccinea*, which, like nearly all its very numerous (150) congeners comes from the Cape, is in general cultivation on account of the beauty of its flowers. See SUCCULENT PLANTS.

Crassus, the surname of several old Roman families, among which that of the Licinii was most remarkable.—(1) LUCIUS LICINIUS, born in 140 B.C., was the best orator of his age, and was as distinguished for his wit as for his rectitude in the capacity of proconsul of Gaul. In 95 he was elected consul, along with Quintus Scævola, who had been his colleague in all his previous offices. During their consulship was enacted a rigorous law banishing from Rome all who had not the full rights of citizens, which embittered the feelings of foreigners toward Rome, and was one of the chief causes of the Social War. As censor in 92 Crassus closed all the schools of the rhetoricians, believing that they exercised a bad influence on the minds of young men. He died in 91 B.C., a few days after vigorously opposing in the senate the democratic consul L. Philippus. Crassus is one of the speakers in Cicero's *De Oratore*, and indeed is the representative of the writer's own opinions.—(2) MARCUS LICINIUS, surnamed *Dives*, the triumvir, was born sometime before 115 B.C. His father was a partisan of Sulla, and on the return of Marius and Cinna to Rome in 87 made away with himself. Cinna spared the boy's life, but subjected him to a jealous and dangerous surveillance, to escape which he went to Spain. He afterwards joined Sulla (83), and distinguished himself in the battle against the Samnites at the gates of Rome. As prætor he crushed the Servile revolt by the conquest of Spartacus at the battle of Lucania (71), and in the following year was made consul with Pompey, a colleague whom he hated. On the other hand, Cæsar valued the friendship of Crassus, the most wealthy of Roman citizens. He was a keen and far-seeing speculator, and devoted his entire energies to the accumulation of money. We are told that he even bought clever slaves, and had them taught lucrative arts that he might enjoy the profits. During his consulate, Crassus gave a feast to the people, which was spread on 10,000 tables, and distributed to every citizen a provision of corn for three months. Plutarch estimates his wealth at more than 7000 talents, and Pliny states that his lands were worth 8000 talents (say £2,000,000). About 60, Cæsar, Pompey, and Crassus entered into

a private arrangement for their common benefit, which paction is known as the first *triumvirate*. In 55, as consul with Pompey, Crassus had Syria assigned him for his province, and began to make preparations of war against the Parthians, hoping both for glory and for gain. The latter end he effected in the meantime by plundering the towns and temples in Syria. At length, however, he set out, but was misled by a treacherous guide, and utterly defeated in the plains of Mesopotamia by the Parthians. Crassus now retreated to the town of Carrhæ, intending to pass into Armenia; but was beguiled into a conference with the Parthian general, Surenas, and was slain at the appointed place of meeting. His head was cut off and sent to Orodes, who is said to have poured melted gold into the dead lips, saying: 'Sate thyself now with that of which in life thou wert so greedy.' His quaestor, Cassius, with 500 cavalry, escaped into Syria; but the remaining Romans were scattered and made prisoners, or put to death.

Cratægus, a genus of Rosaceæ, sub-order Pomæ, very nearly allied to *Mespilus* (Medlar) and *Pyrus* (Pear, Apple, &c.), but distinguished by the acute calycine segments, and by the round or oval fruit, closed at the apex, and concealing the upper end of the bony cells. The species are pretty numerous, natives of the temperate parts of the northern hemisphere, and in general have flowers in beautiful terminal corymbs. They are all large shrubs or small trees, more or less spiny, whence the name Thorn has been very generally applied to them. The only native of Britain is the common Hawthorn (q.v.), (*Cratægus Oxyacantha*). Most of the species resemble it considerably in habit, size, form of leaf, &c. A number of them are now frequent in plantations and shrubberies in Britain, of which perhaps the most common is the Cock's-spur Thorn (*C. crus-galli*), a native of North America from Canada to Carolina. Its leaves are not lobed; its fruit rather larger than that of the hawthorn. The Azarole (*C. Azarolus*), a native of the south of Europe, and the Aronia (*C. Aronia*), a native of the Levant, are occasionally cultivated for their fruit, which is about the size of the Siberian crab, and is used either for dessert or for pies. *C. orientalis* (or *odoratissima*) and *C. tanacetifolia* have also fruit of considerable size. The latter is much eaten in Armenia. *C. mexicana* has a large fruit, like a small apple, but not eatable. It is, however, very ornamental. The wood of most of the species much resembles that of the hawthorn. It is common to graft the rarer species on the hawthorn.—*C. Pyracantha* differs much in appearance from most of the genus; being a pretty evergreen shrub, with lanceolate crenate leaves, and rich clusters of red berries, which remain on it all winter; a native of rocky places in the south of Europe and the Caucasus. It is often employed in Britain as an ornamental covering for walls, and is known as the Pyracantha.

Crater. See VOLCANOES.

Cratinus, a Greek comic poet, born about 519 B.C., who did not begin to exhibit till sixty-five, and who died in 424. Next to his younger contemporaries, Eupolis and Aristophanes, he best represents the Old Attic comedy. He changed its outward form considerably, limiting the number of actors to three, and he was the first to add to comedy the interest of pungent and personal attack. The habits, manners, and institutions of his fellow-citizens he considered a legitimate mark for censorious satire. Even the great Pericles did not escape. Aristophanes repaid him in kind, but his allegation of habitual intemperance Cratinus himself admitted and defended humorously in his *Pytine*. His style was very metaphysical and

ingenious. Of his twenty-one comedies, nine of which obtained the first prize in the public competitions, we possess only some fragments, collected by Meineke in his *Fragmenta Comicorum Græcorum* (Berlin, 1840).—There was also a younger CRATINUS, an Athenian contemporary of Plato, who belonged to the school of the Middle Comedy.

Cratippus, a Peripatetic philosopher, a native of Mitylene, and a contemporary of Cicero, whose son Marcus he instructed at Athens in 44 B.C. Pompey visited him after Pharsalia, and Brutus turned aside to Athens to hear him, even while making preparations to meet Octavius and Antony. Nothing that Cratippus wrote has survived.

Crawford, THOMAS, sculptor, born in New York city in 1814, in 1834 went abroad for his studies, and settled in Rome, where he at first worked under the guidance of Thorwaldsen. Many of his earlier groups have found a place in Boston collections; his later works include the fine group known as the Washington monument, in the capitol park at Richmond, and the bronze figure of Liberty, surmounting the dome of the capitol at Washington. Stricken with blindness in 1856, Crawford died in London, 10th October 1857.

FRANCIS MARION CRAWFORD, novelist, son of the foregoing, was born in Tuscany, August 2, 1854. He had his education at Concord, New Hampshire; Trinity College, Cambridge; Karlsruhe, and Heidelberg. At Rome he devoted himself to the study of Sanskrit, and during 1879-80 was engaged in press work at Allahabad, where he was admitted to the Catholic Church. He was selected by the government committee to write the national ode at the centennial of the American Constitution, September 17, 1887. His first novel, *Mr Isaacs* (1882), was a book of striking and quite unusual merit, and at once found its author an audience. The rich romantic element in certain of the aspects and contrasts of modern oriental life was a distinct discovery to worked-out novelists. Its successors have been *Dr Claudius*, and *To Leeuward* (1883); *A Roman Singer*, and *An American Politician* (1884); *Zoroaster* (1885); *The Story of a Lonely Parish*, and *Saracinesca* (1886); *Marzio's Crucifix*, and *Paul Patoff* (1887); *With the Immortals* (1888); and *Sant' Ilario* (1889). Mr Crawford possesses imagination, originality, and direct vigour, with a graceful and vivid style, and remarkable power of description.

Crawford, WILLIAM HARRIS, American statesman, born in Virginia in 1772, practised law at Lexington, Georgia, and was elected to the state senate in 1802, and to the United States senate in 1807 and 1811. Appointed minister to France in 1813, and secretary of the treasury in 1816, he was a Democratic candidate for the presidency in 1824; but none of the candidates securing a majority, the House of Representatives chose John Quincy Adams. Crawford returned to Georgia, where he was thrice elected circuit judge, and died 15th September 1834.

Crawford and Balcarres, ALEXANDER WILLIAM CRAWFORD LINDSAY, EARL OF, born in 1812, was educated at Eton and Cambridge, and succeeded his father in 1869. He gained a high reputation for his works on religion, philosophy, and art; and his researches into the annals of his own house enabled him in 1848 to successfully prepare the case in assertion of his father's (Lord Balcarres) claims to the premier earldom of Scotland. Besides *Lives of the Lindsays* (1835), and the *Earldom of Mar* (1882), he wrote *Letters from the Holy Land* (1838), *Progression by Antagonism* (1848), and *Sketches of the History of Christian Art* (1847), by which he is best remembered. His dominant idea, however, was the formation of a

perfect library, to which for nearly half a century he devoted great industry and learning; and the library at Haigh Hall, near Wigan, is probably unrivalled among private collections. He died in Florence, 13th December 1880; his body, which for over seven months had been missing from the mausoleum at Dunecht, near Aberdeen, was found in a wood close by in July 1882.—His son and successor, JAMES LUDOVIC LINDSAY, born in 1847, was elected president of the Royal Astronomical Society in 1878-80, and F.R.S. in 1878, and received the degree of LL.D from Edinburgh University in 1882. In 1888 he presented to the nation the admirably equipped observatory at his seat of Dunecht, 12 miles W. of Aberdeen; and it was arranged to transfer the apparatus, with the magnificent astronomical library, to a new observatory to be erected near Edinburgh.

Crayer, CASPAR DE, a Flemish historical and portrait painter, was born at Antwerp in 1582. He lived first at Brussels, and afterwards at Ghent, where he died in 1669. The churches at Ghent contain many of his paintings, which are also common all over Flanders.

Crayfish (*Astacus*, Fr. *écrevisse*), a large fresh-water crustacean, in the long-tailed (*Macrura*) division of the order Decapoda. The body consists of two great divisions, the head and thorax protected by a rigid shield, and the abdomen or tail of six separate rings. The integument exhibits the characteristic Arthropod combination of lime and Chitin (q.v.). There are altogether twenty segments and nineteen pairs of appendages, not including the eyes. The sensitive antennules and antennæ, the six appendages crowded round the mouth, the great claws, the four walking legs, the little swimmerets under the tail, and the pair of large terminal paddles make up the series. These appendages, so different in form and function, are all homologous.

Crayfish (*Astacus fluviatilis*).

The *muscles* are well developed for working the tail, the appendages, and the stomach mill. The *nervous system* consists of brain and ventral chain of ganglia. The eyes are stalked and compound; the ear-sacs with their fringes of auditory hairs and inclosed foreign particles floating in a gelatinous fluid lie at the bases of the antennules, which also bear olfactory bristles. The most remarkable feature in the *alimentary system* is the gastric mill, a complex masticating apparatus in the fore-gut, the essential mechanism of which consists in the rapid clashing of three teeth—one dorsal and two lateral. On the walls of the stomach there are two limy concretions (*gastroliths*) which store lime preliminary to moulting. There is a large digestive gland opening into the small mid-gut; the hind-gut is long and straight. The *circulatory system* consists of a dorsal heart, whence the blood passes by arteries and capillaries to the body, thence

by venous channels to the gills, and thence back again to the heart. The *respiratory system* includes twenty pairs of feathery gills lying under the shelter of the sides of the great shield. The ceaseless baling movement of one of the mouth appendages secures a current of water. The *excretory system* is represented by a 'green-gland' or kidney, lying behind the base of the antennæ, on which its opening, shielded by a prominent knob, may be readily seen. The *reproductive system* consists of three-lobed essential organs with paired ducts opening on the thoracic legs.

The eggs are laid in November or December, and are glued by a secretion to the abdominal legs of the mother. The young are hatched in May to July. They do not differ in any important features from the adults, and the crayfish has thus very much abbreviated the typical life-history. The young escape from the inclosing egg-cases, to which they, however, adhere for a while by means of the strongly incurved claw-tips. The female with its crowd of attached young presents a curious and interesting appearance. The young crayfish moults eight times during its first year of life, five times in the second, twice in the third. The male is adult in its third year, and continues for some time at any rate to moult twice a year. The female is mature in the fourth year, and has only one annual moult. The moulting is in part the result of the fact that the inclosing armature does not grow with the growth of the body. Reserve products of lime and glycogen accumulate before moulting; the old shell virtually dies; a new armature (at first soft) begins to be formed; the animal grows; the old husk, including the hard structures of the stomach, is cast; and the crayfish is left perfectly limp and helpless. The fatigue of the process is shown in the great mortality.

The crayfish is exclusively a fresh-water form, barring the fact that some related genera (*Engurus*, *Cambarus*, *Parastacus*) appear to be for the most part terrestrial. They usually make burrows by the sides of streams, and often lie at the mouths of their holes in wait for passing prey. They are chiefly nocturnal. In their diet they are strikingly omnivorous, eating most things available, from worms to water-voles. Dead animals, molluscs, worms, and insect larvæ form their chief sources of supply. In captivity they may be kept for a while on bread crumbs. In certain cases they do not refrain from eating one another. Their chief enemies are said to be eels and otters.

Crayfishes, though fresh-water forms, have a peculiarly wide distribution. The English and Irish crayfish is a variety of *A. fluviatilis*, and is by authorities designated *A. torrentium*. It occurs all over Europe, except in Scandinavia and Scotland, but is locally limited by the presence of sufficient lime in the water for shell-forming purposes. Another variety of *A. fluviatilis*, *A. nobilis*, is also widely distributed on the Continent. This variety is much cultivated in France and elsewhere for the sake of its dainty though not abundant flesh. They are in best condition from May to August. In ponds for artificial breeding, the animals often fall victims to disease, probably of a fungoid character. In rivers they are sometimes netted, sometimes lured by a light in the darkness. Numerous other species occur both in the Old and New World, and along with the southern forms (*Parastacidae*) may be fairly called cosmopolitan. In the United States, where they are very common, their burrows sometimes cause crevasses or ruptures in the artificial dykes of rivers. The largest species measures over a foot in length. Crayfish-like forms appear in the Middle Mesozoic times, and a somewhat doubtful *Astacus* (*A. philippi*) has been found in the carboniferous limestone of Ireland. It is

probable that they were originally marine. The term crayfish is often extended to the nearly related marine form, the Norway Lobster or *Nephrops norvegicus* (see LOBSTER). See Huxley's *Crayfish: an Introduction to Zoology* (Inter. Sc. Series, 1877).

Crayon (Fr., 'a pencil'). Though used in French, and occasionally in English, to designate pencils generally, including those made of lead, the word crayon is more frequently applied in England to those small cylinders of charcoal, or of pipe-clay or chalk coloured with various pigments, which are used for drawing. Cohesiveness is given to the paste of which the cylinders are formed by means of gum, wax, soap, &c. Crayon drawings are often remarkable for the delicacy and softness with which objects are represented, but they are deficient in power. See PENCIL, CHALK.

Cream is the fat of Milk (q.v.). It exists in minute globules throughout the bulk of milk as it comes from the cow. In virtue of being lighter than the watery portion of milk, cream gradually rises and forms a thin yellowish greasy layer on the surface. *Devonshire cream*, or *clouted* (i.e. clotted) *cream*, is obtained by heating milk in a shallow wide pan on a hot plate or over a slow charcoal-fire. The milk should stand in the pan for twenty-four hours before heating. It usually takes from half an hour to three-quarters of an hour to heat the milk completely; but it must not boil. It then stands for twenty-four hours, when the cream is skimmed off, and a little sugar thrown on the top. *Whipped cream* is cream or milk beat up with white of egg by means of a whisk. *Lemon cream*, *Vanilla cream*, &c. are made with milk, white of egg, and sugar, and flavoured. *Cream cheese* may be made of rich cream, or cream, milk, and rennet, tied up in a clean wet cloth, and kept for some days in a cool place, then put in a finer cloth, and placed for a day or two in a mould, with a weight upon it. The term cream is used frequently for anything superior in quality; thus the French, in referring to persons in the height of fashion, speak of *La crème de la crème*, 'the cream of cream.'

CREAM SEPARATORS (Centrifugal).—The best-known forms are the 'Laval,' the 'Danish,' and the 'Victoria'—the latter a recent invention of a Glasgow firm. Though they differ in form and in detail, the principle involved in the work of separating the butter is common to all. Advantage is taken of the difference existing between the specific gravity of cream and the watery part of milk. While yet warm the milk coming from the cow is run into a strong, spherical, steel vessel revolving at high speed. As the milk is carried round within the vessel (whether revolving horizontally or vertically) it rises up the sides and stands as a wall, thus forming a lining of milk while the speed is maintained. The heavier part inclines outwards, and the light cream is forced inwards and forms an inner layer. From the positions indicated the separated cream and milk are conducted into different channels, and finally into different vessel receptacles. The advantages, as compared with the old method of flat setting (see MILK), are that the cream is got off immediately; no time is allowed for the development of acidity in either the skim milk or cream, and more of the cream present can be removed—the proportion being as 13 is to 11. Small machines driven by hand, costing £13, and separating 12 gallons of milk an hour, do not give quite so good results as those driven by steam. Prices range, for those of sizes capable of separating 45 to 150 gallons of milk an hour, from £24 to £45. A steam turbine has recently been adopted as the means by which power is communicated. The

cost of a turbine separator, capable of doing 90 gallons per hour, is £46. See BUTTER, DAIRY.

Cream of Tartar exists naturally in grape juice, but being insoluble in alcohol, it is gradually deposited, in the form of argol, as the sugar of the juice becomes converted into alcohol by fermentation. In the preparation of cream of tartar the argol is dissolved in hot water, to which charcoal or fine clay is added, to take up the colouring matter; by boiling and filtering a clear colourless solution is obtained, from which, on cooling, the cream of tartar separates as crystals. These crystals, after being exposed on linen for several days, become whiter and constitute the *crystals of tartar*, or, when ground to powder, the *cream of tartar*. Although cream of tartar is, practically speaking, the bitartrate of potash, $\text{KHC}_4\text{H}_4\text{O}_6$ (see TARTARIC ACID), yet it usually contains from 5 to 10 per cent. of tartrate of lime, while adulterants, properly speaking, may also be present. The tartrate of lime is derived from the clay added to purify it, and is more or less present in all commercial samples. In 1888, however, cream of tartar was offered in the market containing 99 per cent. of bitartrate of potash, so that it may be assumed that in future a purer article will be forthcoming. Cream of tartar is readily soluble in hot water, though it takes 60 parts of cold water to dissolve one part of it. *Soluble cream of tartar* is prepared by dissolving together 2 parts of Borax (q.v.) and 5 parts of cream of tartar, evaporating to dryness and powdering. Cream of tartar has an acid taste and gritty feel. When taken repeatedly in small doses of a scruple to a drachm, it acts as a refrigerant and diuretic; in doses of one to two drachms, it is useful as an aperient; and in larger doses of from two to three drachms it acts as a purging agent, accompanied by flatulence and griping. *Imperial liquid* is prepared by dissolving about a drachm of cream of tartar in a pint of boiling water, and adding a little lemon-peel and sugar to flavour it; when an agreeable refrigerant drink is obtained, which is highly serviceable in allaying thirst in feverish cases. Cream of tartar whey is obtained by adding two drachms of the salt to a pint of milk.

Crease, a Malay weapon. See KRIS.

Creasote (Gr. *kreas*, 'flesh'; *sōzō*, 'I preserve') is an oily substance obtained from the tar produced by the destructive distillation of wood. When Coal-tar (q.v.) is distilled, a certain portion called creasote oils passes over, and from this much of the creasote of commerce is obtained. This, although similar in some respects to wood creasote, is quite distinct chemically. The coal product consists largely of carboic acid, along with creasol and xylenol, while the wood product, to which alone the name creasote rightly belongs, consists of gnaiccol, creasol, and phlorol. As it contains several substances, so its boiling-point ranges from 392° to 428° (200°-220° C.). The leading character of wood creasote is that it instantly coagulates albumen, but does not coagulate Collodion (q.v.), in this respect differing from carboic acid. It has a very remarkable power of arresting the decay of meat or wood, and when meat is treated with so small a proportion as one-hundredth of its weight of creasote, and exposed to the air, it does not putrefy, but becomes hard and dry, assuming the taste and odour of smoked meat. Indeed, there can be no doubt that hams cured by means of wood smoke owe their preservation and flavour to some extent to the volatile creasote in the smoke. Railway sleepers and wood liable to be frequently wet are often saturated with the coal-tar creasote; or, where economy is not so essential, with the

wood creasote, and are thereby preserved indefinitely. In toothache, where the cause of pain is a carious tooth with an exposed, inflamed nerve, a drop of creasote, carefully inserted, after previously cleansing the cavity, will often give relief. In this case it acts by coagulating the albumen and destroying the nerves. Creasote acts powerfully on the skin, producing a white stain when applied to it. A few drops added to a pint of ink preserve it from mouldiness. Medicinally, it is given in doses of one or two drops, and has been found efficacious where there is a tendency to fermentation of the contents of the stomach and bowels. Owing to its action on the skin it acts as an energetic poison when taken in large doses.—The Creasote Plant (*Lorrea mexicana*), growing abundantly on the borders of the Colorado Desert, emits a strong odour of creasote. The odour arises from an exudation similar to Indian gum-lac, and is caused by the punctures of an insect, *Carteria Lorrea*.

Creasy, SIR EDWARD SHEPHERD, born at Bexley in Kent, in 1812, from Eton passed to King's College, Cambridge, in 1832, and in 1834 was elected a fellow. Called to the bar in 1837, he went on the home circuit for upwards of twenty years, and presided for three or four years as assistant-judge at the Westminster Sessions Court. In 1860 he was appointed chief-justice of Ceylon, and knighted. Ten years later he came home invalided on a year's leave of absence, after which he went out again, but was obliged to return home finally after struggling with his malady for two years more. He died at London, January 27, 1878. In 1840 he was appointed professor of History in University College. Creasy was the author of *The Fifteen Decisive Battles of the World* (1851), *Invasions of England* (1852), *History of the Ottoman Turks* (1854-56), &c.

Creatin, or KREATIN (Gr. *kreas*, 'flesh'), a constant and characteristic constituent of the striped muscle of vertebrates. It was discovered by Chevreul in 1835, but little was known about it till Liebig published his researches on the *Chemistry of Food* in 1847. Its chemical formula is $\text{C}_4\text{H}_7\text{N}_3\text{O}_2$. Except in one doubtful case, it has always been found as above indicated; it is very uncertain if it ever occurs in unstriped muscles, and it has never been demonstrated in invertebrates. A dehydrated form, known as *Creatinin*, $\text{C}_4\text{H}_5\text{N}_3\text{O}$, occurs as a constant constituent of urine, and has also been demonstrated in fish muscles. Under the influence of acids, creatin becomes creatinin, and by hydration the transformation may be reversed. As these changes may readily occur during extraction, there is often doubt whether creatin or creatinin is present in a given case. See Appendix to Foster's *Physiology*; Krukenberg, *Unters. Physiol. Inst.* (vols. iii.-iv. 1880-81).

Creation. For the scientific discussion of the method by which creation has been effected, reference must be made to the articles DARWINISM, EVOLUTION, MAN, SPECIES, and others; but it may be desirable to make a brief statement here regarding the controversy between Genesis and science. In reality, so far as modern scientific theology is concerned, this controversy is now practically at an end, so that only the briefest historical sketch will be necessary to show the nature of the problem and the steps by which the final conclusion has been reached.

To theology, Genesis had for centuries seemed to affirm that the world was created in six days by successive divine commands. To modern science, on the other hand, the rocks disclosed accumulating evidence that the earth and its forms of life were not 'created' in this sense at all, but

slowly built up or evolved by secondary causes under the control of natural laws. The new scientific position did not traverse the biblical view of the origin of matter or of life; nor did it deny that the laws of nature might be 'the hands of the Living God.' But it claimed that the creation of the world was an ordinary problem for scientific investigation, and that so far as that had gone, some form of development was probably the means by which creation had been brought about. Frankly recognising the right of science to deal with this question, and accepting on certain points the overwhelming evidence of geology, theologians found themselves compelled to reconsider their ground. The first difficulty was that of time. And here they yielded at once by substituting 'periods' for the 'days' of Genesis—an expedient which, whatever literary objection may be taken to it, was certainly allowed by the original Hebrew. Efforts were next made to reconcile these 'periods' with the formations of geology and with the succession of life as revealed by paleontology. Devout men of science worked out these harmonies with great learning and ingenuity, and as new discoveries of science threw their labours aside, fresh workers by further manipulation of the data on either side continued the attempt to bring the apparently rival records once more into line. Prominent among these attempts were the Universal Pre-Adamite Chaos theory of Dr Chalmers; the Partial Chaos theory of Dr Pye Smith; the Vision theory of Hugh Miller; and the cognate though not identical theories of Kurtz and Guyot. Such attempts were at that time perfectly admissible, and even inevitable—invisible because the true direction from which the solution was to come was not yet suspected. But one by one these efforts failed. An attempt by Mr Gladstone, so recently as 1885, elicited a reply from Mr Huxley, who, in the name of modern science, not only repudiated the immediate theory but made it obvious that no reconstruction along that line was ever likely to square with acknowledged facts of science. It is of course always possible to challenge the current reading of a growing science, and the harmonist may still take refuge if he chooses in the fallibility of contemporary interpretations of nature. But on the general question of gradual development *versus* specific creation, the consensus of mature scientific opinion is now so pronounced that any one still clinging to the latter would find it impossible to impress his views upon his age. In some other way, then, the educated mind will seek to reconcile to itself the apparent want of reconciliation between the teaching of nature and the teaching of Scripture.

Stated in a word, the explanation is to be sought for in the fact—recently brought into prominence by the young science of biblical criticism—that the Scriptures really contain no teaching at all upon matters of science. It is an elementary canon of literary criticism that any interpretation of a part of a book or of a literature must be controlled by the dominant purpose or *motif* of the whole. And when one investigates that dominant purpose in the case of the Bible, it is found to reduce itself to one thing—religion. The books of the Bible, respectively, can only be read aright in the spirit in which each was written, with its original purpose in view, and its original audience. Bearing that in view in the case of Genesis it soon becomes evident that a scientific theory of the universe formed no part of the original writer's intention. Could any one with any historical imagination for a moment expect that it would have been? There was no science then. Scientific questions were not even asked then. And to have given men science would not only have been an anachronism, but a source of

mystification and confusion. If the Bible had really aimed at science-teaching, geology would have been one of the last things upon which it would have enlightened mankind. Why was not physiology taught to physicians, or the use of chloroform to surgeons, or of the stars to navigators—matters which would have affected the well-being and actual life of man? In fact it is a first principle of revelation—involvement in the very meaning of the word and proved by its whole expression—that matters which are discoverable by human reasoning and observation should find no place in it, that its subject matter is that alone which men could not find out for themselves. Men could find out for themselves the order in which the world was made. What they could not find out was, that God made it. That therefore was the object of Genesis—theology, not geology. Genesis is a presentation of one or two great elementary religious truths to the childhood of the world. Dating from the infancy of the world, written for children, and for that child-spirit in man which remains unchanged by time, its literary form takes colour and shape accordingly. It is not dedicated to the reason but to the soul. It is a sublime theology, clothed in the most memorable and impressive dress, utilising, purifying, and trans-fusing with the religious spirit some material at least which was common to the cosmogonies of all nations. Now from this point of view the problem of the reconciliation of Genesis with geology simply disappears. The question becomes as irrelevant as when it is asked what the *Paradise Lost* is meant to prove. Science and Genesis are no longer in competition as to which shall be the accepted authority regarding the process of the creation of the world. Genesis does not even enter the field. And in ceding this position it is only to assume, with even greater authority, its legitimate and much higher function.

The strength of this attitude is that it is quite independent of all conclusions of science. Evolution may be true or false, science may change its ground, new discoveries may arise; but these cannot affect the literary and theological province within which wholly this question is now seen to lie. Hence the attack of science is for ever disarmed. And those who assent to evolution, and the many who in its present form do not yet see their way to accept it, may hold an equal truce with Genesis.

As regards the material utilised by the writer in Genesis, it is sufficient to remark that most of it is a common property of the older cosmogonies. The mythology of Persia describes six creative periods of a thousand years; the cosmogony of the Chaldeans is similar; while that of the Etruscans agrees still more closely with the order of Genesis. Thus the Bible did not create this material, nor reveal it. It incorporated it, inspired it, and so made it the vehicle of a revelation.

Crébillon, PROSPER JOLYOT DE, a French dramatist, was born at Dijon, on January 13, 1674. His parents belonged to the middle class, and he was educated in Paris for the law. He soon abandoned a legal for a literary career, and his tragedy of *Idoménée* was successfully produced in 1703. It was followed by *Atrée et Thyeste* (1707), *Electre* (1709), and *Rhadamiste et Zénobie* (1711). The last is his best play, the character of Zenobia being drawn with remarkable power. After writing several other pieces, Crébillon fell into neglect and produced nothing for more than twenty years. He was then pushed forward as a dramatic rival to Voltaire by Madame de Pompadour and other enemies of the great writer, elected to the Academy, awarded a pension of 1000 francs, and appointed royal censor, and one of the royal

librarians. His tragedy of *Catiline*, for which the king furnished the properties, was brought out with great success in 1748. Among his other works were *Xerxes*, *Semiramis*, *Pyrrhus*, and *Le Triumvirat*, the last of which was written when he was eighty-one years old. He died on June 17, 1762. He was a very unequal writer. An oppressive gloom pervades the tragedies which he founded on Greek legend; but occasionally he writes naturally and powerfully. 'Not a few of his verses have a grandeur which has been said to be hardly discoverable elsewhere in French tragedy between Corneille and Hugo' (Saintsbury). Next to Voltaire, he was the best tragic dramatist of his age in France. There are editions of his works by Perelle (2 vols. 1828) and Vitu (1885).—CLAUDE PROSPER JOLYOT DE CRÉBILLON, the younger son of the dramatist, was born in Paris on February 14, 1707. He was educated at the Jesuit College of Louis le Grand, and after writing a number of slight pieces for the stage, acquired great popularity as an author of prose fiction. In 1740 he married an Englishwoman, Lady Stafford. One of his books, *Le Sopha, conte moral*, having given offence to Madame de Pompadour by its indecency, he was banished from Paris for five years, but on his return in 1755 was appointed to the censorship. He was believed by his friends to be dead long before he died on April 12, 1777.

Crèche (Fr., 'manger'), a sort of public nursery where, for a small payment, the children of women who have to go out to work are fed, nursed, and taken care of during the work hours of the day.

Crécy-en-Ponthieu, or CRESSY, a village in the French department of Somme, on the Maye, 12 miles N. of Abbeville. Crécy is celebrated on account of the brilliant victory obtained here, 26th August 1346, by Edward III., with 40,000 English soldiers, over a French army amounting, according to Froissart, to 100,000 men under the command of the Count of Alençon. In this great battle, one of the most honourable to English prowess recorded in history, perished the flower of the French chivalry, as well as the blind king of Bohemia, who was fighting on the side of France. Altogether about 30,000 of the French soldiers bit the dust. In this battle the Black Prince distinguished himself greatly, and gained his spurs (see WALES, PRINCE OF). Pop. 1382.

Credence, a small table placed near the altar or communion-table, at its south side, on which the bread and wine intended for consecration are placed in readiness. In the Greek Church this is called the *trapeza protheseos*, or simply *prothesis*, but is always placed north of the altar, usually in a structural side-chapel. Archbishop Laud was a great stickler for the credence, and pleaded the authority of Bishop Andrewes and other bishops for its use. There are ancient credences in various Anglican churches; among others, in the Collegiate and St John's churches, Manchester, and in the parish church at Ludlow, where they have been in use from time immemorial. Sometimes the place of the credence was supplied by a mere shelf across the Fenestella, or a niche in the south wall of the chancel. The term was also used for a buffet, or sideboard, at which the meats were tasted in early times before being presented to the guests, as a precaution against poison. Hence the origin of the word, which is derived from the Ital. *credenzare*, to taste meats and drinks before they were offered to another, an ancient court practice, which was performed by the cup-bearers and carvers, who for this reason were called in Ger. *credenzler*. The usage is still observed at Rome when the pope celebrates mass, some of the wafers and of the wine to be offered being tasted by the assistant ministers

before they are brought to him as oblation. The introduction or restoration of credences is one of those restitutions of old usages which marked the Oxford movement in England; and they have been judiciously pronounced legal ornaments of the church, as subsidiary or auxiliary to the celebrating of Holy Communion, in order to compliance with the rubrics in that part of the Common Prayer-book.

Credentials, papers or letters given to an ambassador, or other public minister, to a foreign court, in order to enable him to claim the confidence of the court to which he is sent.

Credit, in Political Economy, may be defined as the power to make use of another man's wealth. It rests on the simple fact that when one man has more wealth than he proposes to use himself, he is ready, for a consideration, to lend it to another. The wealth thus lent may be used for purposes either of production or consumption, though the great function of credit in modern industry is to furnish the means of production to those who are in need of them. Credit of course is not capital, but it enables one man to utilise the capital of another. The credit system is an elaborate system of appliances and institutions, by which facilities for lending and borrowing are provided. Bills and bank-notes are well-known instruments of credit. Banks are the most notable institutions of credit, which is further facilitated by companies of every kind, designed to transmit superabundant capital to the most distant colonies and to all the ends of the earth. Credit is thus a mighty organ of industry, whose operations are co-extensive with the world, but it has attained to this far-reaching and cosmopolitan position only in comparatively recent times. Yet it is also one of the oldest phenomena in the history of society, marked by usages and laws, which are of the highest interest and importance. Credit is found in the earliest communities, one of its most striking forms being in the relations of the primitive farming class to the money-lender. It was considerably developed in ancient Greece and Rome, as also in the commercial Phœnician states on the Mediterranean. During the middle ages it grew up in the Italian republics, and afterwards in the cities of Germany and the Netherlands. But its vast extension dates from the great development of commerce and industry connected with the United States, India, and the colonies, combined with the utilisation of steam and the electric telegraph. In short the development of the credit system has gone hand in hand with the development of modern industry. While the credit system has thus so powerfully aided the development of industry by supplying capital to those who have ability and opportunity to utilise it, it is needless to say that it has led to many abuses. In early communities the creditor had power to enslave, maim, or even to slay the debtor. In modern times, by rendering capital accessible to adventurers of every class, it has occasionally given scope for the wildest and most dishonest speculation.

Credit, CASH. See CASH ACCOUNT.

Crédit Foncier ('landed credit'), a system of lending money on the security of landed property, established in France by an edict of 28th February 1852. Its peculiarity is that the loan is repayable by a terminable annuity, the amount and currency of the annuity being so calculated that when the last payment is made, the loan and the interest on it will be extinguished. Or it may be described as a loan repayable by instalments. The borrower, however, has the right of anticipating repayment. The system is precisely regulated by the edict, which prohibits an advance to more than one-half of the value of the property pledged or hypothecated.

Three companies were established by the French government in Paris, Marseilles, and Nevers. They were all formed in 1852, and on 10th December of the same year were amalgamated as the *Crédit Foncier de France*, with the privilege of making such advances. The *Crédit Foncier* stands relatively to real estate as the *Crédit Mobilier* to personal property. The companies formed in Britain to advance money for improvements on landed properties are of a similar character. The *Crédit Foncier* (Limited), formed in London in 1864, was a general finance company. It speculated largely in the promotion of public works at home and abroad, met with heavy losses, and was several times reorganised.

Credit, LETTER OF. This is the term applied to a letter addressed to a correspondent at a distance, requesting him to pay a sum therein specified to the person named, or to hold the money at his disposal, and authorising the correspondent to reimburse himself for such payment, either by debiting it in account between the parties, or by drawing on the first party for the amount. This arrangement may take place between merchants or others, but in general it occurs between bankers residing in different places—e.g. between a banker in London and his correspondent in New York; and it is designed to enable any one who has money lodged at one place to obtain the use of it at another for a small charge, or commission, without the risk or trouble of actually carrying money between the two cities. It is thus a sort of primitive or informal *Bill of Exchange* (q.v.), though not, like a bill, a negotiable instrument. Sometimes the letter is addressed to all or several of the correspondents of the bank issuing it, in which case it is termed a *Circular Credit*; and any of them may pay the sum mentioned, or sums to account as desired, taking the holder's receipt, or his draft on the granter, in exchange; and the sums so paid are *indorsed* on the letter, to show how far the credit has been used. Even where the granter has no correspondent, the holder of an authentic letter will usually have little difficulty in obtaining money upon it; and the system is thus productive of much convenience to all who have occasion to travel.

Some bankers, having an extensive correspondence abroad, issue what are called *Circular Notes*, usually of the value of £10 or £20 each, which any of the granter's correspondents, or indeed any one else, may cash to the holder, on his indorsation and production of a letter of indication. In this kind of credit, the notes are bought outright; whereas for the ordinary letter of credit, the banker debits the drafts under it only when they are advised to him. The introduction (about 1770) of these notes, which have proved of great convenience to travellers, though of little direct profit to the banks, is due to Mr Herries, the founder of the eminent banking-house of Herries, Farquhar, & Co., London.

A *marginal credit* is one in which the due payment of the bills or drafts under it are guaranteed by a third party interested in the transaction; the guarantee being usually expressed in a *marginal note* on the bill. See CIRCULAR NOTES.

Crédit Mobilier. See MOBILIER.

Crediton, or KIRKTON, a borough in the middle of Devonshire, on the Creedy, a tributary of the Exe, 7 miles NW. of Exeter. It lies in a narrow vale between two steep hills, and, having suffered much by fire in 1743 and 1769, is mostly modern. Its church, however, is a fine old cruciform structure. The birthplace of St Boniface (q.v.), the apostle of Germany, Crediton was the seat of a bishopric from 910 to 1050, when it was

transferred to Exeter. Its woollen manufactures are a thing of the past. Pop. (1851) 3924; (1881) 4165.

Creditor. See DEBTOR, BANKRUPT.

Creecb, WILLIAM, Edinburgh bookseller, born 21st April 1745, learned his trade in Edinburgh and London, and spent some time on the Continent before beginning business in 1771. For more than forty years he issued the chief literary productions of that period in Edinburgh, including the first Edinburgh edition of Burns, and the works of Blair, Beattie, and Dugald Stewart, and Mackenzie's *Mirror and Lounger*. He was Lord Provost (1811-13), and died 14th January 1815. His newspaper letters and odd writings collected in *Edinburgh Fugitive Pieces* (1791; new ed. with memoir, 1815), contain much curious information about old Edinburgh, and the way of life of a past generation.

Creedmoor, a village of Long Island, 12 miles E. of New York by rail, with an extensive rifle-range.

Creeds, the authorised expressions of the doctrine of the church at large, or of the several main sections into which it is divided. Such statements of doctrine sprang up naturally in the course of the church's progress. As the doctrines taught by Christ became the subjects of thought, of argument, of controversy, they could not fail to receive a more defined intellectual expression, and to be drawn out into more precise dogmatic statements; and the great creeds, as they rise in succession, and mark the climax of successive controversial epochs in the church, are nothing else than the varying expressions of the *Christian consciousness and reason*, in their efforts more completely to realise, comprehend, and express the originally simple elements of truth as they are recorded in Scripture. Accordingly, the creeds of Christendom grow in complexity, in elaborate analysis and inventiveness of doctrinal statement, as they succeed one another.

What has been called the *Apostles' Creed* is probably the earliest form of Christian creed that exists, unless we give the precedence to the baptismal formula at the close of St Matthew's Gospel, out of which many suppose the Apostles' Creed to have grown. There were in the early church differing forms of this primitive creed: that which is received and repeated in the service of the Church of England has come to us through the Latin Church; and some of its clauses, as, for instance, 'He descended into hell,' and again, 'The communion of saints,' are at any rate additions to the earliest known forms, even if they are not developments of doctrine. A great variety of opinions has been held as to the origin of this creed. It has not only been attributed to the apostles directly, but a legend has professed to settle the clauses respectively contributed by the several apostles. The earliest account of its origin we have from Rufinus, an historical compiler of the 4th century. His statement is, that the apostles, 'when met together, and filled with the Holy Ghost, composed this compend of what they were to preach, each one contributing his share to the one composition, which they resolved to give as a rule of faith to those who should believe.' But Rufinus is no great historical authority, and even learned Roman Catholics (as Wetzzer and Welte) regard the story as a legend. It is not improbable in itself, however, that even in the age of the apostles some formula of belief existed. The exact form of the present creed cannot pretend to be so ancient by four hundred years, but Irenæus repeats a creed not much unlike the present; and Tertullian also affirms that a similar creed had been 'prevalent as a rule of faith in the church from the beginning of

the gospel.' The same thing is proved by the creeds administered to the candidates for baptism in the 2d and 3d centuries. They correspond, with slight variations, to the Apostles' Creed. The true view of this formula of church belief, therefore, seems to be that which regards it as the Roman or Latin form of the creed which prevailed in all the early churches. It is not strictly apostolic; but it is substantially apostolic—fairly representative of the different elements of Christian faith as handed down from the apostles.

The *Nicene*, or rather the Niceno-Constantinopolitan Creed is the next great expression of doctrinal truth that we meet with in the history of the church. It sprang out of the conflict, which had begun even in the 2d century, as to the dignity and character of Christ. (For the various Christological doctrines, see CHRIST, CHURCH HISTORY.) These debates continued more or less throughout the 3d century; and early in the 4th Arius denied that Christ was 'of the substance of God,' or 'without beginning;' he was only the highest of created beings, in a sense divine, but not the same in substance with the Father, nor equal with him in power and glory. Athanasius came forward as the opponent of Arius, and the contest raged throughout the church. The Council of Nicæa was summoned in 325 by Constantine, with the view of settling this controversy, and the Nicene Creed was the result. There were these three parties in the council—the Athanasians, or extreme orthodox party; the Eusebians, or middle party; and the Arians, or heretical party. The heretics were few in number, and possessed but little influence; but the Eusebians were a strong party, and for some time resisted certain expressions of the orthodox or Athanasians, which seemed to them extreme and unwarranted. At length the Homœousians, as the Athanasians were called, prevailed; and Christ was declared not merely to be of like substance (*homœousios*), but of the same substance (*homoousios*) with the Father. At the later Council of Constantinople (381), the additional tenet of the divinity of the Holy Spirit was added, and the creed completed in the form in which it is familiar in the mass and in the communion service in the Book of Common Prayer, except the memorable phrase 'and from the Son' (*filioque*). This phrase, teaching the procession of the Holy Spirit from the Son, which was destined to be the subject of controversy between the Eastern and Western Churches (see Greek Church), seems to have been added by the Western Churches in the 5th and 6th centuries.

The next remarkable monument of doctrinal truth in the church is what is called the *Athanasian Creed*, a product probably of the 5th century, much later than Athanasius himself, but representing, with great formal minuteness and fidelity, his doctrine of the Trinity, as apprehended and elaborated by the Western Church. See ATHANASIAN CREED.

The Apostles', the Nicene, the Athanasian, may be said to form the great catholic creeds of the church. After the time of the last-mentioned formula, there is no general symbol of faith that claims our attention till the period of the Reformation. When the eye of free criticism and argument was turned upon Scripture, new creeds, or rather confessions, began to spring up; these are treated at CONFESSIONS. The *Professio Fidei Tridentina*, commonly known as the *Creed of Pope Pius*, arose out of the *Decrees of Trent*, and is practically the Confession of Faith of the Roman Catholic Church (q.v., and see TRENT). This was published in 1564, but some important additions to it were made in 1870, in consequence of the decision of the Vatican Council.

It is remarkable that the oriental churches have never formally accepted any creed except the Nicene, without the insertion of the word *filioque* in connection with the Procession of the Holy Spirit (q.v.).

See Smith's *Dictionary of Christian Antiquities*; the *Encyclopædia* of the Roman Catholics Wetzer and Welte; the works of Dr Heurtley of Oxford; of the Lutheran Dr Caspari; and the three volumes of the Presbyterian Dr Schaff (Lond. 1877). Among patristic treatises may be specially named the Catechetical Lectures of St Cyril of Jerusalem, in the 4th century, and somewhat later the tractates of St Augustine, *De Fide et Symbolo*; *De Symbolo ad Catechumenos*. In the 17th century an English prelate, Bishop Bull, received the thanks of the Gallican Church, led by Bossuet, for his *Defensio Fidei Nicenæ*, and Bishop Pearson and Dean Jackson won lasting fame by their respective volumes on the Apostles' Creed. On the Roman Catholic side the learned Jesuit Petau (Petavius) is conspicuous, and in 1832 Möhler published two volumes entitled *Symbolik*, which treated of the Reformed and Roman Confessions. See ARTICLES, ATHANASIAN CREED, CONFESSIONS, THEOLOGY.

Creek, in Geography, is a small inlet on a low coast, and in rivers formed by the mouths of small streams. In America and also in Australia, the term creek is applied to small rivers.

Creeks, or MUSCOGEES, a formerly powerful tribe of American Indians, of the Appalachian stock, who, reduced by war to some 25,000, were in 1836 removed from Georgia and Alabama to Indian Territory. In 1872 their number was estimated at 13,000.

Creepers (*Certhiæ*), a genus of Passerine birds, the type of the family Certhiade. The bill is long, much curved, laterally compressed, and pointed; the tongue is long, narrow, sharp-pointed, and jagged near its tip; the tail is rather long, and the tips of the tail-feathers are firm and pointed, extending beyond the webs. The feet are rather slender; the hind-toe about as long as the others. The feet are well adapted for tree-climbing, and the stiff feathers of the tail are also employed for support. There is probably more than one species, but this is doubtful, and the distribution is somewhat wide. The Common Creeper (*C. familiaris*) is

Common Creeper (*Certhia familiaris*).

found in all temperate parts of the northern hemisphere, wherever woods abound. It is a permanent resident, but is never numerous or gregarious. It is not so well known as many other birds, in consequence of its restless habits, its rapid movements, and prompt retirement to the farther side of the tree from the spectator. The Scotch name, *Bark-speeler* ('climber'), describes its almost con-

stant habit. The usual course of action is a rapid jerky ascent up the trunk, and then a headlong flight to the root of the next tree. It searches for insects and their larvae in the crevices of the bark. The nest is usually formed in a hole of a decayed tree. The creeper is one of the smallest of British birds, although considerably larger than the wren. The continental species or varieties are said to be really songsters, but in Britain only the males are known to sing, and that only at the breeding season. A shrill monotonous cry is all that is usually heard. Its prevalent colour is dark gray above, with spots of yellow and white; the under parts are white. Like other members of the family, the creeper is of much importance in clearing insects from forest trees.—The Wall Creeper (*Tichodroma muraria*) of the south of Europe frequents walls and the faces of rocks; it has a more slender bill, and the tail-feathers are not pointed.—The Nuthatch (q.v.) is a closely allied genus.

Creeper. See CLIMBING PLANTS.

Crema, a town of Lombardy, 27 miles NW. of Cremona by rail, with a cathedral (1341). Pop. 8251.

Cremation, the reduction of the dead human body to ashes by fire, was a very early and widespread usage of antiquity. The early Aryans—as opposed to the non-Aryan aborigines of India—the Greeks, Romans, Slavs, Celts, and Germans, burned their dead, so that cremation may be regarded as the universal custom of the Indo-European races. The graves of North Europe throughout the 'bronze age' contain only jars with ashes. It was Christianity that gradually suppressed the practice of cremation. In India it is still a usual method for disposing of corpses, and is also practised by numerous uncivilised peoples of Asia and America (see BURIAL). A return to the practice has been strongly insisted on by many in modern Europe. This is opposed mainly on grounds of kindly feeling for the dead, and for religious reasons connected with the belief in the resurrection of the dead. Advocates of cremation assert that these are prejudices founded on misapprehension, and allege that the question is solely a sanitary one. The damage to the health of such as live near churchyards and cemeteries, from the exhalations of noxious gases and the poisoning of water supplies, is an indisputable fact, and is in many cases quite inevitable. By burning, the body is reduced more swiftly to its constituent elements, without disrespect to the dead or hurt to the living. The ashes of the body of an adult after due incineration weigh from 5 to 7 lb. Others allege as the juridico-criminal difficulty that cremation might be made to destroy the evidence of murder (as by poisoning); but advocates of cremation answer that a properly organised system of medical inspection would obviate this objection. In Italy cremation has been legal since 1877, and is not unusual at Milan, Lodi, Cremona, Brescia, Padua, Varese, and Rome, and at these places crematory furnaces, on the Gorini system, have been erected. About 1000 cremations have taken place in these and other Italian towns. In Berlin, Dresden, and Leipzig there has been strong agitation in favour of cremation; and at Gotha there is a large mortuary and crematorium, where between 1878 and 1888 more than 550 bodies had been cremated and lodged in the Columbaria of the crematory temple. Societies for securing the legalisation of the process exist in nearly every country in Europe, and in some the rite of cremation is permissible. At present this is not so in Belgium, Russia, or Austria. Two crematory furnaces were erected in 1888 by the municipality of Paris at Père-la-Chaise. The movement found for long but little favour in the United

States; thus, there were but twenty cremations between 1875 and 1882, but now several crematories are in frequent use in North America. Interest in this movement was awakened in England in 1874 by Sir Henry Thompson: the council of the society established in that year purchased ground at Woking, in Surrey, in 1878, and there erected a crematory on the principle of that at Lodi. This apparatus had by 1889 consumed forty human bodies in the most complete manner. For each cremation about seven shillings' worth of wood fagots and coal are needed. The time occupied in the reduction of an adult varies from 1½ to 1¾ hours, and the ashes weigh, as before stated, from 5 to 7 lb. Cremation having been declared legal in England, it is expected that some of the large cities will very shortly possess these media for destruction of the body by fire. The human body consists of 60 per cent. of water and 40 per cent. of solid matter; and quickly to reduce this to ashes requires a strong furnace. A special form of Siemens' regenerator furnace is that which has found most favour in Germany, but elsewhere only the Gorini form of apparatus is used. The Gorini crematory furnace consists of a receiver, a furnace, and a chimney. The receiver is a flat-bottomed chamber open at each end, one of which communicates with the upper part of the furnace, and the other with the lower part of the chimney. The furnace, which discharges its heat into the receiver, is somewhat spacious, sufficiently so to produce the necessary heat by means of wood fuel only if found requisite. The chimney is also of sufficient sectional area to remove the products of combustion from the receiver as well as the furnace, and high enough to permit the draught to keep above the gases pervading the receiver, and prevent any dispersion of heat or smoke through the apertures around the receiver or cremation chamber. In order to perfectly overcome the idea as to any organic molecules escaping from the shaft, a grating is placed near the base of the chimney, and upon this a portion of coke is kept burning. The products of animal combustion which issue still highly heated from the receiver, are subjected to higher temperature in passing through the burning coke, and any organic matter which may have resisted or escaped the first combustion is destroyed by the second, and mixes harmlessly with the atmosphere. The literature of the subject began with Thompson's *Treatment of the Body after Death* (1874); Erichsen's *Cremation of the Dead* (1887); Ullersperger's *Urne oder Grab* (1874); and some works by Italian doctors. The *Transactions* (vol. ii.) of the Cremation Society of England contain a complete bibliography on the subject up to date. Since 1874 upwards of 3000 works and pamphlets have been published on this subject in various countries.

[While this volume was passing through the press, the author of the above article died, and his body was cremated at Woking.—ED.]

Crémieux, ISAAC ADOLPHE, jurist and politician, was born of Jewish parents at Nîmes, 30th April 1796, and became an advocate in Paris in 1830. In 1842 he entered the Chamber, and in 1848 was a member of the provisional government. Imprisoned at the *coup d'état*, he subsequently confined himself to professional work, till 1870, when he was a member of the government of national defence. He was made a senator in 1876, and died 10th February 1880. He was the founder of the *Alliance Israélite Universelle*.

Cremona, a decayed city of Northern Italy, on the north bank of the Po, 60 miles SE. of Milan by rail, and 46 E. of Pavia. Cremona has some fine buildings—the principal the cathedral (1107–1606), with gorgeous interior; the neigh-

bouring octagonal Baptistery; the Palazzo Publico (1245); the so-called Campo Santo; and the famous Torrazzo (1288) or belfry—the loftiest campanile in Italy, being 396 feet high, and commanding magnificent views over the fertile plains of Milan. By means of the Po, Cremona carries on a considerable trade in the produce of the district; and it has manufactures of silk, cotton, earthenware, and chemicals. In the 16th, 17th, and 18th centuries it was greatly celebrated for its manufacture of violins, the most famous makers being the Amatis, the Guarneris, and Stradivari (see VIOLIN). Pop. 31,930. Cremona is the capital of a province of the same name; area, 632 sq. m.; pop. (1886) 314,755.

Cremonne Gardens, near Battersea Bridge, on the north side of the Thames, a very popular place of amusement for Londoners down to 1877, when they were closed.

Crenelle, a Battlement (q.v.), or an embrasure in a battlement.—CRENELLE, in Heraldry, embattled, signifies that any ordinary is drawn like the battlements of a wall.

Creole (Span. *criollo*), in general an individual born in the country but not of indigenous blood, a term applied, especially in the former Spanish, French, and Portuguese colonies of America, Africa, and the East Indies, to natives of pure European blood (*sangre azul*), in opposition to immigrants themselves born in Europe, or to the offspring of mixed blood, as mulattoes, quadroons, Eurasians, and the like. In Brazil the native whites call themselves *Brasileiros*. Creole dialects are corruptions of French, Spanish, Portuguese, English, or Dutch, arising in various colonies, and may be studied in such formal treatises as Thomas, *The Theory and Practice of Creole Grammar* (Port of Spain, 1869) and Quentin, *L'Histoire de Cayenne et de la Grammaire Créole* (Paris, 1872). Mr Cable's stories revealed to English readers the singularly quaint charm of the phraseology and manners of the Creole population of Louisiana.

Creosote. See CREASOTE.

Crescendo, in Music, means a gradual increasing of sound, or changing from piano to forte and fortissimo. It is marked thus < , or with the abbreviation *cresc.* The converse is *decrecendo*. The swell of a good organ produces a most perfect crescendo.

Crescent. A representation of the half-moon with the horns turned upwards, called a crescent, is often used as an emblem of progress and success. It was the emblem of the Greek before it became that of the Turkish rule; but it was not adopted by the Turks from the Greeks, as is often said. It had been used by them hundreds of years before, in Central Asia. Genghiz Khan's Tartars had the crescent on their banners, and so had the Janissaries of Sultan Orchan.

Crescent, a decoration, sometimes called order of, in Turkey. In 1799, after the battle of Aboukir, the Sultan Selim III. testified his gratitude to Nelson by sending him a crescent richly adorned with diamonds. It was not intended as an order, but Nelson wore it on his coat; and Selim, flattered by the value attached to his gift, resolved that a similar decoration should be conferred on foreigners who have done service to the state. There was an old Order of the Crescent, instituted by René, Duke of Anjou, in 1464.

Crescentia. See CALABASH TREE.

Cress, a name given to many plants belonging to the order Crucifere, which have in common, in greater or less degree, a pungent mustard-like taste, and antiscorbutic, diaphoretic, and other medicinal qualities. They are very generally distributed abundantly over the temperate and northern

countries of the earth, and much used as salads and medicinally by the peoples of those countries. In Britain the most commonly used is the Common Cress (*Lepidium sativum*), of which there are several

Common Cress
(*Lepidium sativum*):
a, silicle.

Bitter Cress
(*Cardamine amara*):
a, silique, opening.

varieties, the most favoured being that known as the Curled Cress. Sown thickly in soil in moderate heat under glass, this may be raised during winter in a few days; and the seeds spread out thickly on flannel, which is kept saturated with warm vapour, as from a boiler or tank of boiling water, will vegetate and yield a crop within 48 hours after sowing. In this way it has been found invaluable during arctic voyages as an antiscorbutic. The Poor Man's Pepper is the Broad-leaved Cress (*L. latifolium*), a native of Britain, and formerly used as a condiment by the poor. The Virginian Cress (*L. virginicum*) has similar properties to the Common Cress, and is cultivated in Britain, in North America, and in the West Indies for use as a salad. *L. pisidium*, a native of the South Sea Islands, is there used to stupefy fish, and by sailors as an antiscorbutic. The allied genus *Barbarea* supplies the Winter Cress or Yellow Rocket of gardens (*B. vulgaris*), a native of Britain, and the American Cress (*B. precox*), by some regarded as merely a variety of the preceding, is also a native of Britain, the European continent, and America, where both are used for the purposes already described. The Bitter Cress (*Cardamine amara*), the Lady's Smock or Cuckoo-flower (*C. pratensis*), and the Hairy Cress (*C. hirsuta*), are all natives of Britain and of other temperate and northern countries of the globe, but being more bitter than

Water Cress
(*Nasturtium officinale*).

pungent, are less used in salads in this country than on the Continent and in America. Water Cress (*Nasturtium officinale*) is an aquatic perennial species of the same natural order, largely cultivated in England and on the Continent in slowly running brooks and ditches, where the water is pure and the bottom gravelly. In stagnant water and a muddy bottom the plant soon perishes. For *Indian Cress*, see *TROPÆOLUM*.

Cresset, a name given to a great light on a beacon or watch-tower, to a lamp or torch, or a light fixed on a pole.

Cressy. See *CRECY*.

Crest (Lat. *crista*, 'a comb or tuft'), a heraldic figure or ornament, which in its original use surmounted the helmet. Though often popularly regarded as the most important part of the heraldic insignia of a family, it is, in the eyes of heralds, an accessory without which the bearing is complete. The practice of ornamenting the helmet with a capriciously assumed figure existed in classical times; but no such usage is found in the early middle ages, or at the time when heraldry had its rise. Crests first appear occasionally on the helmets of knights in the 13th century, and were a mark of dignity and estate beyond what was implied by the use of arms. Edward III. was the first English king who assumed a crest; and crests are found in use by the early Knights of the Garter. The practice gradually spread, particularly in England, till the crest became the almost indispensable adjunct of a shield of arms, as it now is. On the Continent there are still many families of distinction who have never used a crest. The crest is generally placed on a Wreath (q.v.) of the principal metal and colour of the shield; sometimes, however, it is (by permission of the sovereign or king-at-arms) allowed to issue out of a ducal coronet, mural crown, or cap of maintenance. Different crests are, in modern times, often assigned to separate branches of the same family, and there are many crests which so many families have in common that they are hardly distinctive. No ladies except sovereign princesses can, with any propriety, attach a crest to their arms. The assumption of crests by churchmen is equally objectionable. Corporations occasionally use them, a practice for which precedent may be shown from the 15th century. Crests are not to be confounded with family badges, which were never placed on a helmet, and ought not to be borne on a wreath. See *BADGE*; Fairbairn's *Crests* (2 vols. new ed. 1882), and Knight and Butters' *Crests* (2 vols. 1885).

Creste, in Architecture, an ornamental finishing, either in stone, or of tiles or metal, running

Creste, 13th century (from Viollet le Duc).

along the top of a wall or the ridge of a roof. Such crestings were adopted by the Romanesque architects from the East, but the designs were soon made after their own style. Elaborate ornaments of this kind were frequently used in Gothic buildings. In modern times cast-iron has been greatly

used for such ornaments, many roofs being covered with gilded iron rails or crests.

Crested, in Heraldry. When a cock or other bird has its comb of a different tincture from its body, it is said to be crested of such a tincture, naming the tincture.

Creston, a town of Union county, Iowa, 115 miles W. of Ottumwa. It is connected by railway with Burlington, Chicago, and St Joseph, and has large machine-shops and railway-carriage works. Pop. (1870) 411; (1885) 7393.

Creswell, SIR CRESWELL, judge, born in Newcastle in 1794, was educated at Charterhouse and Cambridge, and called to the bar in 1819. Between 1822 and 1830 he issued, with Barnewall, a valuable series of *Reports*; in 1830 he was appointed recorder of Hull, and in 1834 a king's counsel. He was returned to parliament by Liverpool in 1837 and 1841, and in 1842 Peel made him a puisne judge. He sat in the Court of Common Pleas till 1858, when he was appointed first judge of the newly-created Probate and Divorce Court, the success of which was mainly due to his unsparing exertions. He died 29th July 1863.

Creswick, THOMAS, R.A., a popular landscape-painter, was born at Sheffield, 5th February 1811. He early exhibited a taste for drawing, and removed to London in 1828, where two of his pictures during that year found a place in the Royal Academy's exhibition. Creswick loved to paint the beautiful streams, and glens, and wooded dells of his native land; and these, which, along with some coast scenes, form the subject of his best paintings, are represented on his canvas with great delicacy of finished detail and truth of aerial perspective, the figures introduced being frequently from the brush of Ansdell, Cooper, Frith, and other artists. He was well known as a book-illustrator by his drawings for the wood-engravers, and he contributed to the publications of the English Etching Club. He was elected an A.R.A. in 1842, an R.A. in 1851. He died 28th December 1869. More than a hundred of his works were collected in the London International Exhibition of 1873.

Cretaceous System, the highest division of the Mesozoic or Secondary strata, rests conformably upon the Jurassic System (q.v.), and is overlaid unconformably by the oldest deposits of the Eocene System (q.v.). The cretaceous strata of Britain are confined chiefly to the east and south-east of England. They form the Yorkshire Wolds, extend over large parts of Norfolk, Suffolk, and Hertford, and compose the Chiltern Hills, Salisbury Plain, the Downs, and the south part of the Isle of Wight. On the Continent the cretaceous rocks have a considerable development. They form a broad basin in the north of France, and stretch eastward from Belgium, Holland, Denmark, and the south of Sweden, through the great plains of northern Europe to the south end of the Ural Mountains. But over extensive regions within that wide area they lie more or less concealed under younger formations. There is another extensive development of cretaceous strata in southern Europe, where they enter largely into the composition of many of the Mediterranean coast-lands. The chief petrological feature of the cretaceous strata of western and northern Europe is the great development of white chalk in the Anglo-French area, and its gradual replacement, when followed eastwards into Germany, &c., by earthy limestones, shales, sandstones, &c. The most marked characteristic of the cretaceous system in southern Europe is the great development in that region of massive marine limestone (hippurite limestone).

In North America cretaceous strata likewise occur in force, especially in the western states and

territories. They also occupy wide tracts in the Gulf states, whence they extend up the Mississippi valley to the Ohio; they put in an appearance at intervals on the Atlantic borders between South Carolina and New Jersey; and we meet with them again on the Pacific border and in the coast-range. Strata of the same age occur also in the far west of British America, at the mouth of the Mackenzie River, and in Greenland. In India the system is marked in the Deccan by a massive series of basalt-rocks, 4000 to 6000 feet thick, and covering an area of 200,000 sq. m. In Australia and New Zealand there is a considerable development of cretaceous rocks, such as the 'desert sandstones' of Queensland, and a small coal-bearing group of beds. In New Zealand the system likewise contains coals, some of which are lignites, while others are bituminous coals of fair quality. The following is the succession of cretaceous strata in England:

Upper Cretaceous—	
Upper Chalk.....	600 feet.
Middle Chalk.....	200 "
Lower Chalk and Chalk Marl.....	450 "
Chloritic Marl and Upper Greensand.....	250 "
Gault.....	300 "
Lower Cretaceous—	
Lower Greensand.....	550 "
Wealden Series.....	1850 "

The Wealden Beds consist largely of clay and sand, and are almost entirely of fresh-water origin. In Yorkshire, however, the strata which occur on the same horizon as the Wealden beds of the south are of marine origin, as seen in the Speeton clay near Bridlington. The Lower Greensand, consisting of sand, clay, &c., are marine. The Gault (q.v.), a tough blue clay, is likewise marine, and so also are the shallow-water sands of the Upper Greensand, and the thin layer of chalky marl called Chloritic Marl (q.v.), which is characterised by the presence of glauconitic grains and phosphatic nodules. The most characteristic rocks of the system, however, are the chalk beds. The basement of these beds is the argillaceous chalk known as Chalk Marl. The lower chalk is a grayish-white chalk, while the middle chalk is a pure white chalk, containing in its upper portions layers of flint nodules. A hard layer of yellowish limestone called Chalk-rock lies at the top of this division. The upper white chalk is a thick massive white chalk, containing numerous layers of nodules and occasional tabular sheets of flint. All these chalks are of marine origin. The following are the divisions adopted by continental geologists, and now largely used by geologists in Britain:

Continental Cretaceous.	Equivalent English Strata.
Danian.....	(wanting).
Senonian.....	Upper Chalk.
Turonian.....	Middle Chalk.
Cenomanian.....	Lower Chalk and Chalk Marl.
	Chloritic Marl.
	Upper Greensand.
Albian.....	Gault.
Neocomian.....	Lower Greensand.
	Wealden.

The cretaceous strata of Britain being almost exclusively of marine origin, it is not surprising that land-plants seldom occur, and that they are met with chiefly in the fresh-water beds near the base of the system. They consist chiefly of ferns, cycads, and conifers—a flora resembling that of the preceding Jurassic period. The upper cretaceous rocks of Germany, however, have furnished many plant remains. Amongst those are the oldest known dicotyledons, such as extinct species of maple, oak, walnut, beach, laurel, magnolia, &c., also several proteaceous plants. A similar admixture of forms occurs in the cretaceous strata of North America. Amongst animals the Protozoa played a very important part—the white chalks

and earthy limestones being very largely composed of the minute shells of foraminifera, such as Globigerina, Rotalia, and Textularia, which still swarm in the ooze of the Atlantic. Sponges, such as *Ventriculites*, *Siphonia*, &c., were very abundant, and sea-urchins also occurred in great numbers. Star-fishes and bryozoans were fairly common, as were also, amongst brachiopods, *Terebratula* and *Rhynchonella*. But the brachiopods as a class were feebly represented as compared with their abundance in the earlier stages of the world's history. Ordinary bivalves, however, were very numerous, such as *Inoceramus*, *Hippurites*, *Spondylus*, *Lima*, *Pecten*, &c. In the Danian beds carnivorous gasteropods begin to abound, and they include a number of existing genera. Cephalopods are not only the most abundant, but also the most characteristic fossils of the cretaceous rocks. Amongst them are a great variety of Ammonites, and many forms of *Belemnites*. Amongst the fishes were ganoids, and various kinds of the shark tribe, together with the earliest representatives of the Teleostei—which include most living genera of fishes. The waters of the period seem also to have swarmed with reptiles, such as *Ichthyosaurus* and *Plesiosaurus*. Winged reptiles were also present, such as *Pterodactylus*. Amongst dinosaurs were *Cetiosaurus*, *Megalosaurus*, and *Iguanodon*. Another remarkable reptile was the serpent-like *Mosasaurus*. Besides these, there were lizards, chelonians, and crocodiles. The American cretaceous system is likewise characterised by the presence of huge dinosaurs and other reptiles—some of them being European types, while others are peculiar. One of the most remarkable features of the American rocks, however, is the occurrence in them of the toothed birds—*Ichthyornis* and *Hesperornis*. (Separate articles deal with most of these various forms.)

No break separates the Jurassic from the cretaceous system—there is a gradual passage from the upper beds of the former into the lower beds of the latter. At the beginning of cretaceous times most of the British and Irish area existed as dry land. Over the south-east of England lay the estuary of a large river, flowing probably from the north. The Wealden beds are the delta-deposits of that river; the English and French beds of this division covering an area of 20,000 sq. m. The sea into which that river flowed occupied a considerable area in the north of France, spread over the Low Countries into Hanover, filled the basin of the North Sea, and overflowed a portion of eastern England. Wealden beds occur in north-west Germany, and indicate the delta of a river, like that of the British area, flowing from the north. While land-conditions predominated in northern and middle Europe, an open sea covered vast areas in southern Europe. Gradual subsidence of the sea-bottom took place during the deposition of the Wealden series, and eventually the great deltas became submerged, and a wide sea covered most of what are now the low grounds of the British area, and passing eastwards, submerged vast regions of middle Europe up to the slopes of the Ural Mountains. The depression was greatest in the western areas, where in the deep clear waters there gradually accumulated the calcareous matter which subsequently formed our white chalk. There is no deposit forming at present which is quite analogous to white chalk. The calcareous oozes of existing seas which most resemble it are of abyssal origin, but the sea in which the chalk accumulated probably did not exceed 1000 or 2000 feet in depth. The extreme purity of the chalk, consisting as that rock does of 95 per cent. and more of carbonate of lime, is difficult to account for on the supposition that the sea in which it formed was comparatively shallow.

The sea of western Europe may have been dotted with small islands—from none of which large rivers descended; and possibly the formation of the chalk was not so slow a process as many geologists suppose. Professor Prestwich even suggests that it may to some extent be of the nature of a chemical precipitate thrown down under special and peculiar conditions prevailing at the time. However that may be, the shells of foraminifera and other organic remains certainly enter very largely into its composition. In the Mediterranean basin, a deep open sea would seem to have persisted all through the cretaceous period. It was in this sea that the massive hippurite limestone was formed. Open water appears at this time to have extended through the Mediterranean area into Asia, covering there also vast tracts of what is now dry land, and communicating with the Indian Ocean. The conditions of climate seem to have been remarkably uniform over vast regions of the earth's surface. Ferns, cycads, and conifers flourished in the lands within the Arctic Circle, and the waters of the same region were tenanted by cuttlefish, ammonites, and huge reptiles.

Crete (Ital. *Candia*, Turk. *Kirit*, Gr. *Krētē*), a Turkish island in the Mediterranean, is the most southerly portion of Europe. It is 60 miles S. of Cape Malea in Greece, 110 SW. of Cape Krio in Asia Minor, 100 SSW. of Rhodes, and 300 W. of Cyprus. Its length is 156 miles; its breadth varies from 30 to as little as 7 miles; and its area is 3326 sq. m., or twice the size of Hampshire. The climate, inferior only to that of Rhodes, is excellent, and has always been celebrated for its salubrity. The air is pure, fresh, and bracing; the rainfall about 27 inches. In July, August, and September it is hot in the plains, but the sea-breezes temper the heat, especially at night, and during the rest of the year the climate is delightful.

Crete is for the most part mountainous, especially in the west, where the White Mountains form the most important range. In the centre Mount Ida, now called Upsilonliti, the loftiest in Crete, rises to a height of 8055 feet. The east is less mountainous, and everywhere numerous small valleys are exceedingly fertile. The rivers are unimportant, being almost invariably dry in summer, and in winter and spring rushing down to the sea as torrents. The country is, however, fairly well watered, even in the dry season, as springs abound all over the island.

The coast-line, deeply indented on the north, includes some good harbours: Suda Bay, on the north, is one of the finest anchorages in the Mediterranean, and now well known by name as the resort of the British fleet at interesting political crises; and on the south is the small but well-sheltered Kaloi Limenes, or the Fair Havens, by which name it is spoken of in Acts, xxvii. 8. In the immediate neighbourhood of Crete are three islands: Clauda, the modern Gavdo, off the south-west coast, with an area of about 15 sq. m., also spoken of in Acts, xxvii. 16, was in the middle ages the see of a bishop. At the present day it is remarkable for its lighthouse, whose brilliant revolving light—flash every minute—is visible at a distance of 25 miles. Dia, eight miles north of Candia, and Grabusa, at the extreme north-west, were both fortified by the Venetians as strongholds in their wars with the Turks.

Wheat and fruit are the most important products. Oranges and lemons particularly flourish. The grapes are good, but the wine, though abundant and cheap, is of very inferior quality. In the middle ages the wine made at Malevesi, near Canea, was celebrated under the well-known name of Malinsey (Fr. *Malvoisie*). The forests, as usual in the Levant, have almost entirely dis-

appeared. But on the hills the cypress flourishes, and in the plain country the olive is the most important tree. Chestnuts, valonia oak, and carobs also grow in certain localities. The principal exports are olive-oil, soap, carobs, wool, cheese, valonia acorns, and fruits. Sheep are largely bred, and the wool is exported, but is not of fine quality. Sponges are found upon the coast. There are few wild animals, the most important being the Cretan ibex; there are no serpents of any kind, and there is a paucity of game, whether of fur or of feather.

The population, in 1881 numbering 279,000, chiefly of Greek descent, consists of 204,700 Christians and 74,300 Mohammedans, although these latter are rarely Turks, but native Mussulmans, speaking Greek and not Turkish as their mother-tongue. There are also 700 Jews and only 250 Roman Catholics. The Cretans are a turbulent race, of proved and proverbial mendacity, bold, independent, and hard to govern. Their subjection to the Ottoman Porte is more nominal than real. They are practically independent, they pay no taxes to Stamboul, and the viceroy who represents the dominion of the Porte in the island is invariably a native or 'Greek' Christian.

Crete had once, according to Homer, 'a hundred cities.' There are now but three towns of any importance: Megala Kastron or Candia, pop. 14,000; Rhithymnos, or Retimo, 8000; and Canea or Khania, the residence of the governor and of the foreign consuls, about 23,000.

History.—The early Cretans were seafaring Greeks, rivals of the Phœnicians. The island was the favourite resort of colonists from every part of Greece (*Odyssey*, xix. 175), and was celebrated at once for its climate, its laws, and its great law-giver, judge, and king, Minos. Crete was subdued by the Romans in 67 B.C. under Q. Metellus, called in consequence Creticus. It was occupied in succession by the Saracens and the Greek emperors, with varying fortune, until in 1205 it passed under the dominion of Venice, in whose hands it continued for over 450 years, till it was conquered by the Ottoman Turks in 1669. In 1821 the Greek insurrection was heralded by an outbreak in Crete. From 1830 to 1840 Crete was administered by the Viceroy of Egypt by order of 'the Powers.' There were revolts against the Turks in 1859 and 1866, and a great measure of freedom and independence was granted to the Cretans in 1868, which was confirmed by the Treaty of Berlin. See Spratt's *Travel and Researches in Crete* (1865), and C. Edwardes' *Letters from Crete* (1887).

Cretinism, from Fr. *crétin*, 'an idiot of the Alps,' and this again probably from *chrétien*, 'a Christian,' one who, from his state of fatuity, could not sin, and was viewed with some degree of religious respect (cf. the frequent use of 'innocent'). The name cretinism is now applied to idiocy or defective mental development of a particular type, associated with bodily deformity or arrested growth. Cretinism occurs occasionally in most parts of the world, but particularly in connection with enlargement of the Thyroid Gland (q.v.) or Goitre (q.v.), in the lower Alpine valleys, not only of Switzerland and Italy, but of the Pyrenees, Syria, India, and China. In Europe it is rarely met with at a higher elevation than 3000 feet, and haunts chiefly the valleys surrounded by high and steep walls of rock, which exclude the light, and limit the free circulation of air. In some such localities it is extremely prevalent. Cretins are always pitiable and frequently repulsive objects; they are generally dirty, shameless, and obscene; their appetite is commonly voracious; the mouth is large and open, the tongue often protruded, the eyes small, the nose flat and broad, the skull flattened above and

expanded at the sides, the forehead retreating, the complexion cadaverous; in addition to which, the whole body is dwarfish, the skin thick and coarse, the hands and feet large, the limbs often rickety, the belly protuberant. Recent investigations have shown that the connection between cretinism and goitre is an extremely close one. The disease called Myxœdema (q.v.) closely resembles cretinism, except that it comes on during adult life; and it has been proved to be always associated with destructive change of the thyroid gland. A similar condition has also been found to follow the removal of the thyroid gland by surgical operation in a large proportion of cases. It is, therefore, probable that loss of the function of the thyroid gland is the essential factor in the production of cretinism, while goitre consists in its enlargement. It is as yet quite uncertain, however, why the inhabitants of particular districts are so liable to disease of this organ. Many attempts have been made to improve the condition of the cretin in childhood, by removing him from the locality of his birth, and by careful training; the institution founded by Dr Guggenbühl on the Abendberg, near Interlaken in Switzerland, having been the prototype of many others on the Continent, and of some in England and Scotland, for the education of idiots.

Cretonne, originally a white cloth of French manufacture, is a name now applied to a printed cotton fabric used for curtains or for covering furniture, which was introduced about 1860. Chintz (q.v.), so much employed for the same purpose in former years, is a comparatively thin printed cloth usually highly glazed. Cretonne, on the other hand, is generally thick and strong for a cotton fabric, and with a twilled, crape, basket, wave, or other figure produced on the loom. When a pattern is printed on this uneven surface (it is sometimes plain), it has a rich, soft appearance. A cretonne is rarely calendered or glazed. The thick weft threads of inferior qualities are commonly formed of waste cotton, and the patterns upon these, though often bright and showy, are as a rule printed in more or less fugitive colours. Some cretonnes are now printed on both sides with different patterns.

Creuse, a river and a department in the centre of France. The river rises near Féniers, on the northern slope of Mont Oduze, and flows 146 miles north-westward till it falls into the Vienne, a tributary of the Loire, 12 miles N. of Châtellerault. —The department, with an area of 2150 sq. m., had a population of (1872) 274,663; (1886) 284,942. Low mountains and chains of hills, 2000 to 3000 feet high, occupy the greater part of the land. The climate is moist and variable, and the soil thin and light, interspersed with stretches of heath and pasture in the southern hilly district, but better in the lowlands of the north-east. The rearing of cattle forms the chief industry, and large quantities of chestnuts and fruit are grown. Coal is mined at Ahun. The people of Creuse, who use a rude patois, annually migrate in large numbers to find work in various parts of France. Creuse is divided into the arrondissements of Aubusson, Bourgneuf, Boussac, and Guéret, with Guéret for its capital.

Creusot, LE, a town in the French department of Saône-et-Loire, 14 miles SSE. of Autun, and 236 SSE. of Paris. Situated in the midst of a district rich in coal and iron, it owes its importance to the establishment here in 1837 of the great ironworks of Schneider & Co., which rank amongst the largest in the world. They occupy 770 acres, and turn out yearly 190,000 tons of pig-iron, besides steel rails, iron rails, and locomotives. Pop. (1846) 4012;

140

(1886) 17,703. See Vadot, *Le Creusot, son Histoire, son Industrie* (1875).

Creuzer, FRIEDRICH, a learned German philologist, was born at Marburg, March 10, 1771, and studied there and at Jena. In 1802 he was called to a chair at Marburg, and in 1804 to that of Philology and Ancient History at Heidelberg, which he filled till his retirement in 1845. Here he died, 15th February 1858. Creuzer's first and greatest work was his perversely ingenious and learned *Symbolik und Mythologie der alten Völker, besonders der Griechen* (4 vols. Leip. 1810-12). His symbolical explanation of ancient mythologies was assailed by Hermann, Voss, Lobeck, and Pott. His next work in importance was a complete edition of the works of Plotinus (3 vols. Oxford, 1835). With G. H. Moser, Creuzer edited several of the philosophical works of Cicero. Most of his writings are collected in the series of *Deutsche Schriften* (1837-54), which contains also his autobiography, under the title *Aus dem Leben eines alten Professors*, subsequently divided and arranged into *Deutsche Lehr- und Wanderjahre* and *Paralipomena*. In 1854 appeared his *Opuscula Selecta*.

Crevasse. See GLACIER.

Crevecoeur (Fr., 'heart-breaker'), a once famous Dutch fort in the province of North Brabant, at the confluence of the Meuse and the Dieze, 4 miles NNW. of Bois-le-Duc. It figures in history from 1587 to 1794.

Crevillén, a town of Spain, 20 miles WSW. of Alicante. Pop. 8683.

Crew, of a ship, is a collective name for all the persons employed therein, but usually limited to designate petty-officers and seamen only. In men-of-war, the entire crew are divided into five groups: (1) Commissioned and warrant officers; (2) chief petty-officers; (3) first-class petty-officers; (4) second-class petty-officers; (5) able seamen, ordinary seamen, non-combatants, and boys. In the royal navy there are upwards of 180 different ranks, grades, or offices among the crew, excluding officers and marines.

In the case of a merchant-ship about to proceed on a foreign-going voyage from a British port, the crew sign the agreement between the shipowner and themselves (usually called 'the articles') in the Mercantile Marine Office in the presence of the officers of the Board of Trade; and on returning to the United Kingdom, the master must lodge the articles at the Mercantile Marine Office within forty-eight hours of his arrival, and the crew are discharged there. Seamen leaving the vessel abroad must be discharged before the British consul, and new engagements abroad must be made before the same official. In the case of vessels in the coasting trade, the crew sign articles on board the vessel, but the agreements are handed over to the Mercantile Marine Offices every June and December. Vessels under 80 tons hand over their crew-lists only, in the same manner. There is no statutory scale for manning British ships, but the Passengers Act requires that a ship carrying emigrants shall be manned with an 'efficient' crew to the satisfaction of the emigration officer clearing her. Owing to improvements in masting and rigging, the use of better mechanical appliances, and the necessity for economical working, merchant-ships' crews are now smaller than in former years, except in the best class of passenger vessels.

Crewe, a town of Cheshire, with a great railway junction and the huge works of the London and North-Western Railway, to which it owes its present importance. It is 158 miles NW. of London, 43 SE. of Liverpool, 31 SSW. of Manchester, and 53 NW. of Birmingham. About 1840

there were only two or three houses where Crewe now stands; but since then its population has grown to 4491 in 1851, 8159 in 1861, 17,810 in 1871, and 24,385 in 1881—chiefly employed in the railway stations, and in the world-famous locomotive and carriage works, which were commenced in 1843. Naturally, Crewe is not an attractive place, though the London and North-Western Company have erected a good many handsome buildings, done much in the way of sanitation; and in 1887-88 presented the town with a beautifully laid-out park of 40 acres. Crewe was incorporated in 1877. Lord Crewe's seat, Crewe Hall, by Inigo Jones, was destroyed by fire in 1866, but has been since rebuilt.

Crewel-work is a kind of embroidery in fine worsted or silk. See EMBROIDERY.

Crewkerne, a market-town of Somersetshire, in the fertile valley of the Parret, 15 miles S.E. of Taunton. It has a cruciform Perpendicular church, with a splendid west front; a grammar-school (1499), occupying commodious new buildings; a railway station (1860); and manufactures of sail-cloth, girth-web, hair-seating, &c. Pop. (1851) 3303; (1881) 3557. See Pulman's *Book of the Ace* (4th ed. 1875).

Cribbage, a game at cards, probably of English origin. It does not appear in foreign treatises on games, and in the *Academy of Play* (1708), translated from the French, cribbage is called an English game. Cribbage is played with a pack of fifty-two cards; the scores accrue in consequence of certain combinations in play, hand, and crib (for an account of which see any treatise on the game). The scores are marked on a cribbage board pierced with holes. Cribbage was formerly called *noddy*. It is mentioned under that name in an epigram by Sir John Harrington (1615). Nares (*Glossary*) says noddy was not played with a board; but Gayton (*Festive Notes upon Don Quixot*, 1654) speaks of noddy-boards. The earliest description of the game is in *The Compleat Gamester* (1674). Under cribbage it is stated that the game was sixty-one, 'set up with counters;' and that knave-noddy is one in hand and two to the dealer—i.e. if turned up. In 1791 Anthony Pasquin (pseudonym) published a treatise on the game of cribbage; and in 1800 cribbage was added to revised editions of Hoyle's *Games*. The most comprehensive work on the game is Walker's *Cribbage Player's Handbook*, long out of print, but republished in great part in Bohn's *Handbook of Games*.

Crib-biting is a bad habit and an unsoundness met with especially in the lighter breeds of horses, and those spending a considerable amount of leisure in the stable. The act consists in the animal seizing with his teeth the manger, rack, or any other such object, and taking in at the same time a deep inspiration, technically called *wind-sucking*. Crib-biting springs often from idle play, may be first indulged in during grooming, especially if the operation is conducted in the stall, and the animal be needlessly teased or tickled; is occasionally learned, apparently, by imitation from a neighbour; and in the first instance is frequently a symptom of some form of indigestion. Its indulgence may be suspected where the outer margins of the front teeth are worn and rugged, and will soon be proved by turning the animal loose where he can find suitable objects to lay hold of. It usually interferes with thriving and condition, and leads to attacks of indigestion. It can be prevented only by the use of a muzzle or throat-strap; but in those newly-acquired cases resulting from gastric derangement, means must further be taken to remove the acidity or other such disorder.

Crichton, JAMES, surnamed the 'Admirable,' son of Robert Crichton of Elioock, Dumfriesshire, Lord Advocate of Scotland, was born on 19th August 1560. He was educated at St Salvator's College, St Andrews, where George Buchanan was his tutor, and where he graduated M.A. in 1575. In 1577 Crichton left Scotland. He was for two years in France, where he seems to have served in the French army. There is no trustworthy evidence that he distinguished himself as a disputant at the university of Paris. In July 1579 he was at Genoa, and addressed the senate in a Latin oration, which was printed. Next year he reached Venice, and printed a Latin poem addressed to the scholar Aldus Manutius, grandson of the founder of the Aldine press. Aldus took the youth under his patronage, and issued a printed handbill announcing a great scholastic disputation in which Crichton was to take part. The young Scotchman was there described as a skilled athlete, scholar, poet, linguist, with unparalleled powers of memory. In 1581 (according to Aldus) Crichton went to Padua and overcame all the scholars there in public disputations. At the end of 1583 Aldus issued an edition of Cicero's *De Universitate*, dedicated to Crichton's memory, and asserted there that his versatile protégé died on 3d November 1583. No details are given, and although Aldus's date has been widely adopted, it is clearly an error. In 1584 Crichton visited Milan. There late in that year he published an elegy on the death of the archbishop, Cardinal Borromeo, and two gratulatory odes—one addressed to the cardinal's successor, Gaspar Visconti, and the other to Charles Emmanuel, Duke of Savoy, on his marriage. Early next year (March 1585) he issued a collection of scattered Latin poems dedicated to the chief-magistrate of Milan. This is the latest date at which he is known to have been alive. In 1591 Crichton's younger brother Robert had become owner of his father's property in Scotland. Hence Crichton died between 1585 and 1591. In 1601 one Thomas Wright, in *Passions of the Mind*, related that when in Italy he heard that a young (unnamed) Scotchman, 'of most rare and singular parts,' was attacked by an (unspecified) Italian prince in disguise; that the prince, running some risk from the Scotchman's sword, announced his name; that the Scotchman, who was previously acquainted with the prince, handed him his sword, and the prince thereupon basely ran his opponent through the body. John Johnston, in *Heroes Scoti* (1603), states that Crichton was killed at Mantua by a son of the duke in a nocturnal brawl, and that he was buried at Mantua. Crichton's early 17th-century biographers combine Wright's and Johnston's stories, adding such doubtful details as that Crichton was tutor to his assailant, the Duke of Mantua's son, on the recommendation of Pope Clement VIII. Wright and Johnston were practically contemporaries of Crichton, and the outline of their story is doubtless true. But the fatal encounter at Mantua must be dated at least two years later than the date of Crichton's death supplied by Aldus. John Johnston in 1603 first used the epithet 'admirable' in describing Crichton ('*omnibus in studiis admirabilis*'), and it was again employed in David Leitch's *Philosophia illacrymans* (1637). But Crichton chiefly owes his popular reputation, as well as his designation of 'the Admirable,' to Sir Thomas Urquhart of Cromarty, who wrote an extravagantly fantastic account of the scholastic and athletic prowess which he displayed at Paris and Mantua in his *Discovery of a most exquisite Jewel* (1652). There is little that is historical in Urquhart's fables, although they have been largely accepted by later biographers, including P. F. Tytler, the first edition of whose biography of

Crichton appeared in 1819, and the second in 1825. Aldus's testimony to Crichton's versatility is alone worthy of serious consideration. Aldus was in the habit of praising extravagantly promising young strangers at the Italian universities, and ascribes to a Polish contemporary of Crichton, Stanislaus Niegowski, almost the identical accomplishments with which he credits Crichton. That Crichton's power of memory was extraordinary, is, however, independently corroborated by a physician of Treviso near Venice, named Bartolomeo Burchelati, in his *Epitaphiorum Dilogi Septem* (1583). And there is no reason to doubt his linguistic facility or his skill as a fencer. But the numerous Latin verses and prose essays which Crichton printed indicate no special capacity. Harrison Ainsworth wrote a novel on Crichton's apocryphal career in 1837. For a critical and bibliographical account, see articles in *Dictionary of National Biography*, and in *Gentleman's Magazine* for March 1888 (both by Sidney L. Lee). A genealogical paper by John Stuart in *Proceedings of Society of Antiquaries of Scotland* (1855), ii. 103-18, is also useful. Unique copies of most of Crichton's publications are in the Grenville Library of the British Museum.

Cricket. Like that of most games played with a ball, the origin of cricket may be said to be lost in obscurity. Numerous researches have been made in the hope of fixing a date, but no really satisfactory conclusion has been arrived at, though it is tolerably certain that the game, in some shape or form, existed at a very remote period of antiquity. Various attempts have been made to prove that the birthplace of cricket was outside the limits of Great Britain; but the weight of evidence favours the popular view that to England alone the world is indebted for this manly and universally-liked game. It is considered highly probable that the word cricket is a corruption of *creag*, a variation of an old Saxon word signifying a game played with a crooked bat; if so, it would appear that cricket was known amongst us nearly 600 years ago, as the word is found to have been in use during the reign of Edward I. (1300). This, however, is supported only by material of slender character. Strutt, one of our best authorities on ancient sport, adduces some evidence to show that 'club-ball,' played in the 14th century, may have been the parent of cricket, but both 'cat-and-dog' (mention of which occurs in the 16th century) and 'stool-ball' (frequently referred to in the 17th century) have a closer affinity. It is stated in Russell's *History of Guildford* that cricket was played in that well-known Surrey town in the middle of the 16th century, but for fifty years subsequently no trace has been found; and indeed history tells us really little or nothing of the game that is not speculative until the opening of the 18th century, from which period its growth may be readily followed, though scarcely anything of a definite character is to be gleaned even at that time as to the mode of playing the game. While it was then generally admitted to be healthful, it was condemned on account of the amount of gambling associated with it.

There is some evidence of a match having been played between Kent and All England previously; but the earliest matches of which copies of the scores have been preserved were those of Kent v. All England, decided on the Artillery Ground, Finsbury, in 1746, and of Hambledon (a club started about 1750, and which held a somewhat similar position to that afterwards taken up by the Marylebone Club, inasmuch as the Hambledonians played matches in different parts of England, and generally promoted the interests of the game) against Kent, which took place at Bishopscourt Paddock, near Canterbury, August 19, 1772.
